USING THIS BOOK

Chilton's MOTORCYCLE REPAIR MANUAL has been designed for maximum ease of use by the experienced owner or mechanic, while providing, at the same time, detailed information on basic concepts and procedures which are needed by the beginner.

To accomplish this goal, a "General Information" section is included at the front of the manual, and the novice should refer to this first before attempting the operations outlined in the individual model sections.

The "General Information" section contains all of the basic information necessary for motorcycle maintenance and tune-up, including such items as tips on lubrication, decarbonization, cable and chain care and adjustments, breaker points, ignition timing and the use of timing lights, spark plug readings, and carburetor theory and troubleshooting.

Also included is an "Engine Rebuilding" section which covers typical rebuilding operations such as inspection of cylinders, pistons, valves and guides, camshafts, bearings and seals, as well as providing helpful hints on engine work.

While most of the information contained in "General Information" is applicable to the great majority of motorcycles, exceptions and special cases will, of course, be noted in the individual sections.

Necessary specifications are included either in the test or collected in charts at the end of the related section.

SAFETY NOTICE

Proper service and repair procedures are vital to the safe, reliable operation of all motor vehicles, as well as the personal safety of those performing repairs. This manual outlines procedures for servicing and repairing vehicles using safe effective methods. The procedures contain many NOTES, CAUTIONS and WARNINGS which should be followed along with standard safety procedures to eliminate the possibility of personal injury or improper service which could damage the vehicle or compromise its safety.

It is important to note that repair procedures and techniques, tools and parts for servicing motor vehicles, as well as the skill and experience of the individual performing the work vary widely. It is not possible to anticipate all of the conceivable ways or conditions under which vehicles may be serviced, or to provide cautions as to all of the possible hazards that may result. Standard and accepted safety precautions and equipment should be used when handling toxic or flammable fluids, and safety goggles or other protection should be used during cutting, grinding, chiseling, prying, or any other process that can cause material removal or projectiles.

Some procedures require the use of tools specially designed for a specific purpose. Before substituting another tool or procedure, you must be completely satisfied that neither your personal safety, nor the performance of the vehicle will be endangered.

GLOSSARY OF COMMON TERMS 73

GENERAL INFORMATION

The "General Information" section following is intended to provide an overview of the various motorcycle component systems and the maintenance and service procedures pertinent to them. Because of the similarity of these systems among motorcycles in general, most of the material here is applicable to the overwhelming majority of machines currently on the road. There are always some exceptions to the rules, however, and this must be borne in mind when applying this material to individual bikes.

The subsections under "General Information," such as "Maintenance," or "Tune-Up," correspond to the organization of each of the individual model sections. We recommend that the novice mechanic or new owner first master the general principles in this portion of the book, and then apply them to the specific machine in question. For specific information on your machine, however, always refer to the individual model procedures. This section is provided not only to avoid repetition of common procedures, but to allow easier and faster information retrieval when using the model sections.

INTRODUCTION

There is no guarantee that every motorcycle owner will be able to perform every procedure contained in this book, nor is this even likely. Some jobs require special tools which may be extremely expensive, while others will require a great deal of experience and skill which comes only with ample practice or a gift for the job at hand. There is no reason to be discouraged, however, since every motorcycle owner of even modest mechanical skills can use this manual to help keep his or her motorcycle in peak condition—a state of affairs which is not only financially important, but, from the aspect of riding safety, absolutely imperative.

Routine tune-up and maintenance procedures on many machines can be carried out by the owner with only a few simple hand tools and careful attention to detail.

We recommend that the novice read the following sections carefully before beginning any work.

USING THIS MANUAL

Individual model procedures are divided to group similar or related operations under convenient headings.

Be sure your machine is listed there before you begin work. The following subsections are designed to cover the various component systems which comprise the motorcycle.

The "Maintenance" section deals with those routine operations necessary at periodic intervals to keep the machine on the road: lubrication of the engine, drive line, forks, and controls; adjustments of cables, brakes, and chains; and checks of tires, wheels, lights, brakes, and other related and safety items. At the end of each "Maintenance" section is a list of the manufacturer's recommended lubricants, factory recommended maintenance intervals, and other data such as oil capacities, tire pressures, etc.

The "Tune-Up" section involves periodic adjustments or checks of the valve assembly, ignition system, and carburetors. In this portion is information relating to plugs and points, cam chains, valve clearances, and so on. Tune-up specifications are summarized in a chart at the end of the section.

"Engine and Transmission" gives detailed instructions for the removal, repair, and installation of the motor and its parts, including checks for wear, replacement limits, and other necessary specifications.

The oil pump, pressure relief valves (where applicable) and other oil-related components can be found in the "Lubrication System."

The "Fuel System" deals with carburetor rebuilding and petcock service.

"Electrical Systems" is concerned with the charging components (alternator/generator, rectifier, voltage regulator), ignition parts which are not a cause or routine maintenance (coils, etc.), and switches, safety devices, or other electrical items applicable.

"Chassis" includes rebuilding procedures and service operations on forks, brakes, and other parts of the rolling frame.

Since service procedures for many items are similar regardless of their design or manufacturer, basic information common to all or most of the machines covered in this manual has been deleted from the individual sections, and has been collected in this "General Information" section. This has been done not only to avoid repetition of material, but to make the manual easier to use.

Less experienced owners are urged to refer to this section first before attempting any of the operations outlined in the manual.

Before beginning any job with which you are not familiar, read the given procedures thoroughly. This will not only give you a good idea of what is involved, but will prepare you for any unexpected occurences. It will also allow you to have all of the necessary tools and spare parts on hand at the outset. Some parts, such as gaskets or seals, must always be replaced if they are disturbed. Have them ready before beginning. Any work is made easier if all of the necessary materials are readily available.

Of special importance are the so-called "special tools" which may be necessary in any given operation. Sometimes these are general purpose items such as gear or flywheel pullers which are usable in a number of different places, while at other times they are single purpose items designed and made for a specific job on a particular motorcycle. The latter type may be very expensive or difficult to obtain, or it may just not be cost efficient for the individual owner to purchase one which he or she may use only rarely. Occasionally it is possible to get around using the special factory tool, but very often it is not. The frustration that the lack of the proper tool can cause, and the damage to fragile components which can be done with improper working procedures, must be experienced to be believed. We have attempted to make things as easy as possible for the owner without special equipment by mentioning alternatives to special tools in those cases where they exist and can be employed without danger to the mechanic or the machine. In most cases, however, there is simply no safe substitute for the factory-recommended equipment, and these instances, too, are pointed out in the working instructions. All users of this manual are urged to abide by this commonsense approach and avoid "shade tree" methods of working on the motorcycle. There are simply too many variables which can lead to mechanical damage and/or personal injury if the correct methods and the proper tools are not used.

SAFETY PRECAUTIONS

Several steps must be taken, depending on the nature of the job you are doing, to avoid the risk of personal injury either to yourself or to other persons in the vicinity of the motorcycle or work area. Once again, a commonsense approach is the safest path to follow. Generally, however, the following precautions are always applicable although this list is not all inclusive.

1. Make sure that the motorcycle is securely parked on a hard, level surface, and is on the centerstand unless the job requires the sidestand to be used.

2. If the engine is to be started or run as part of the operation, be sure that the bike is in an open, well-ventilated area. Doing a tune-up in a closed garage is simply not safe. Keep the door open regardless of how cold it is outside.

3. Take care to keep children and other innocents away from the work area—especially if the engine is running. Never leave a running motorcycle unattended.

4. Keep gasoline or other flammable fluids well clear of a running motorcycle. Have plenty of rags on hand to mop up any gas or oil spills immediately.

5. Keep a fire extinguisher on hand in your work place. Be sure to get one which is suitable for fuel and electrical fires. This should be considered an absolute necessity—especially if you do most of your work in the garage or basement.

6. Study the nature of unfamiliar materials before you try to use them. For example, adding the hardening catalyst to fiberglass resin produces an *exothermic* reaction: it gives off a great deal of heat. It is vital that this be considered before you try mixing up a batch. Other materials produce noxious fumes. Be sure to read all of the warning labels and instructions for use on all containers.

7. Always use protective clothing or devices if they are called for. Safety glasses should be in every work area. Protective face mask filters are also a good idea if the operation you are performing is going to produce a fair amount of fine particulate matter.

8. Misusing tools can cause personal injury. Never attempt to use a tool for a job for which it was not intended just because it is handy or looks like it might work.

9. Try to work in a place which allows you to move around the motorcycle without tripping over things. Try to move safety hazards out of the way. Be careful when moving around in a close space. Remember that it is relatively easy to lose your balance when jumping up and trying to get from one

spot to another in an undue hurry. This is not meant to be amusing. For example, crouching by the side of a bike, it is easy to forget that the end of the handlebar is just a few inches above your head. Getting up suddenly can get you a nasty bump or worse.

10. Never forget that the engine gets very hot when running, and it gets especially hot if it is sitting still. The hottest part of a running engine exposed to touch is the exhaust pipe header. Remember this when reaching around an engine to make an adjustment.

11. If it becomes necessary to rig a potentially unstable device such as a fuel tank propped up to allow access to vacuum screws, be absolutely certain that the tank is firmly secured while the adjustments are being made.

Above all, let common sense be your guide. There is nothing inherently dangerous about working on a motorcycle provided that proper precautions are taken.

NECESSARY TOOLS

This topic is included for the benefit of the owner who is working on his or her own motorcycle or those of friends. A long-time owner/mechanic may have already accumulated a large selection of tools over a period of years. A relative newcomer, however, is faced with the problem of what to buy. This can be an expensive investment, since good tools cost money, and it is really not economical to buy things you may seldom or never use. Your tool requirements will largely depend on the type of work you are willing or able to do yourself, and, of course, on the kind of machine you ride. The toolkits which come with motorcycles vary in quality from "fair" to very good. In general, however, most consist of only a few open-end wrenches and a number of special sockets for items such as axle nuts and spark plugs, and screwdriver bits. Unfortunately, these tools are not always of the highest possible quality.

Most riders will profit from the purchase of a basic set of high-quality hand tools. We recommend that you spend the extra money for a good set of tools now, rather than trying to save a little on cheaper items which may have to be replaced in a few years. Well-known brand name tools got that way because of their quality, and investing in this type will seldom be disappointing.

Your tools will more than likely be metric since all Japanese, Italian, and German motorcycles are built to metric specifications.

For those who intend to do more than the most basic work, the following items are recommended:

a. A set of open-end wrenches;

b. A set of twelve-point sockets with ⅜ in. drive ratchet. Get a set which includes a couple of extensions. As your need for more sophisticated equipment becomes available, you will find that there are any number of attachments, adapters, and swivels which will make your socket set extremely flexible;

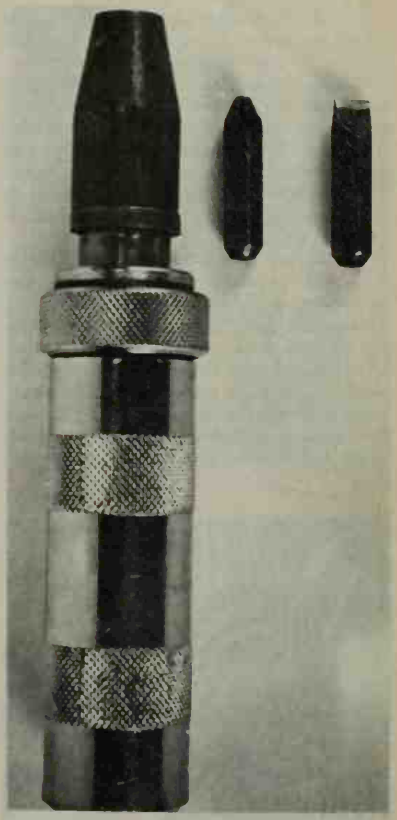
c. A selection of Phillips and slot-head screwdrivers;

d. A set of allen keys if your bike is fitted with these fasteners as many of the newer models are;

e. An impact driver with Phillips and slot head bits. This is the one "special tool" to buy if you are only going to buy one. It will repay your initial investment almost immediately, since you will find that it is virtually impossible to remove engine screws on most motorcycles without one. These screws are put on very tightly to begin with, and may sometimes seize in the alloy engine cases. Most attempts to remove them without an impact driver will only succeed in stripping the screw heads. The driver should also be used when installing these screws, since it is hard to get them tight enough to stay on with only a screwdriver. Once the head of a screw is stripped, removing it can be very expensive. Don't take the chance. Get an impact driver.

f. A pair of good tire irons. To remove or install tires, always use tire irons designed for motorcycle tires. Two irons are usually sufficient, although a third can be helpful. Never use screwdrivers, crowbars, or anything else which may pinch the tube, rip the tire carcass, or damage the wheel (which is just about everything else other than a genuine tire iron). When the proper tire lubricant is used, almost any tire can be removed or fitted with the smallish tire irons sold in any motorcycle shop.

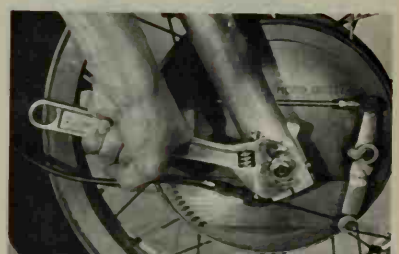
g. A tire pressure gauge. Many different types are available at relatively inexpensive prices. Since the meters attached to the hoses in filling stations are not particularly accurate, a tire gauge is a worthwhile investment. Proper inflation of your tires not only affects tire wear, fuel mileage, and traction, but the safety aspects of the subject should be obvious—especially if you are generally riding two-up or carrying luggage.



These tools may be considered as basic necessities. As you progress in your knowledge of the motorcycle or of motorcycles in general, you may be willing to take on increasingly difficult tasks which may require more specialized equipment. As one example, note that we have recommended twelve-point sockets for a start. Really heavy-duty sockets of the six-point type are also available. These fit directly over the hex bolt or nut giving greater purchase, which is important on slightly rounded nuts or bolts, but will not slip over the fastener as readily as the twelve point type. This may be a disadvantage when working in tight places. In addition, the six-point sockets are usually a bit more expensive.

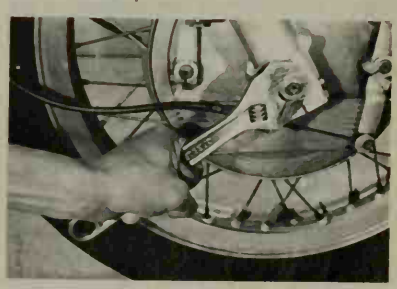
A ⅜ in. drive ratchet will be suitable for most work which you will encounter. For heavy-duty jobs, a sturdier ½ in. drive ratchet is better. Of course, you will still be able to use the ⅜ in. sockets provided that you purchase an adapter.

Large adjustable wrenches are useful for items like axle nuts or situations in which the nut or bolt size is larger and a lot of torque is required. However, adjustable wrenches should not be used in place of precision-sized sockets or open-end wrenches, since they can easily round off a nut or bolt head if not used correctly.



When using an adjustable wrench, always position it on the nut or bolt so that the force will bear against the fixed jaw of the wrench.

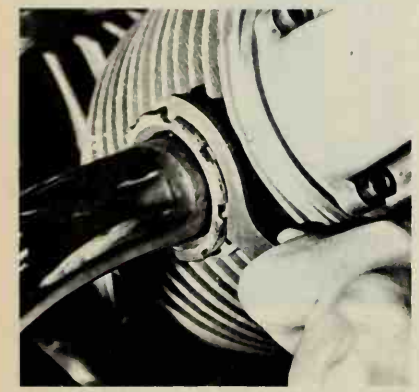
You may find that your machine requires one or more "special tools" which will make a job much easier. For example, a thin-walled socket might be used to get at the cylinder head bolts. You will probably learn these tricks and others like them as you do more work on your own machine.



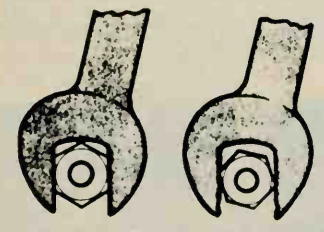
Impact driver and bits

Insofar as factory special tools are concerned, your needs will depend, again, upon the kind of motorcycle you own, and the type of work you intend to do.

Incorrect use of an adjustable wrench (loosening nut)



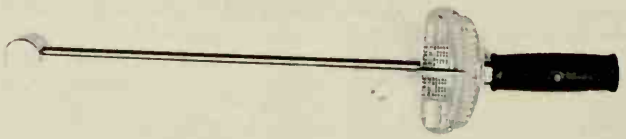
Correct use (loosening nut): stress applied to fixed jaw



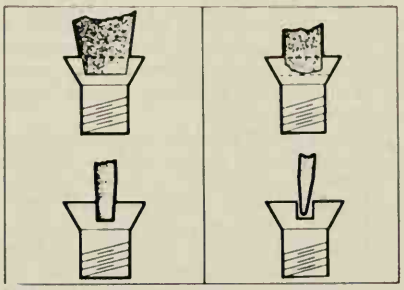
A *magneto flywheel puller* is a basic item which any owner of a motorcycle equipped with a flywheel magneto should consider. Removal of the flywheel is usually required to replace the contact breaker points, and sometimes to adjust the ignition timing, both procedures being within the capabilities of the majority of owners. So a device to remove the flywheel, which is usually press-fit onto a tapered portion of the crankshaft, is handy to have.

The motorcycle manufacturers supply these pullers for their own motorcycles, so this tool will be available at your dealers'.

On some motorcycles, the exhaust pipes are secured at the engine by circular nuts which thread into the cylinder or cylinder head. These nuts are often finned, sometimes not, but always require a *pin wrench* for removal or tightening. A pin wrench which will fit these fasteners is a wise investment.



A pin wrench is a necessity when loosening or securing exhaust pipe nuts such as this



Be sure the wrench fits the nut properly (left)

Another helpful tool, which is becoming increasingly more necessary, is a "*chain breaker*" for use on machines with pressed-on masterlinks on the final drive chain. The masterlink, with its spring-clipped side plate, is the weakest point of the chain, and to remedy the problem of broken chains on the larger motorcycles, more manufacturers are fitting "endless" chains which require a chain breaker to remove and to install the masterlink.

Other tools, which might be worth the initial investment depending upon how often you use them, include a *plastic mallet*. There are numerous uses for this tool, for example, breaking loose a clutch cover, oil pan, or other alloy casting which stays put even after its screws have been removed. A steel hammer will certainly damage parts like this, and prying it off may damage the gasket mating surface.

A beam-type torque wrench

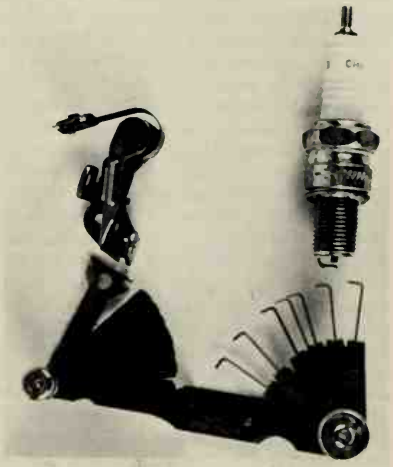
Keep your screwdriver tips in good shape (left)

A *torque wrench* is a necessity for installing cylinder heads and any other large parts which are secured by a number of bolts. Proper tightening of the fasteners is required due to the stresses involved, and an *even* tightening is required to prevent warpage or distortion and ensure a good seal. Proper torquing of axle nuts and suspension parts is a safety item. On two-strokes, which will require relatively frequent removal of the cylinder head(s) for routine decarbonization, a torque wrench is an essential tool. Distortion of the head due to improperly tightened bolts is a very real danger, and proper installation become even more imperative on multi-cylinder motorcycles in which the head is a single casting.

There are two types of torque wrenches—the beam type and the click type. Click-type (or breakaway) torque wrenches can be set to any desired setting and will automatically release once the setting is reached. These are used mostly by professionals, and are not really necessary for the backyard mechanic. The beam-type torque wrench, while not quite as accurate or as fast to use as the click-type, is perfectly adequate for everyday use, and quite inexpensive. When using a torque wrench on any fasteners, keep the socket as straight as possible on the fastener. Trying to torque something on an angle just won't work.

Feeler Gauges

Feeler gauges are needed for jobs like adjusting valves, setting breaker point gaps, gapping spark plugs and so on.



Blade-type feeler gauges are suitable for valves and points, but spark plugs should be gapped with wire-type gauges, most of which also come with a small lever for bending the side electrode.

Most feeler gauges are stamped with their thickness in both English and metric measure. One type, which is known as a "go-no-go" gauge is very easy to use since each blade has two thicknesses. It is therefore obvious whether the gap being set is within tolerance.

No matter what gap you are setting with a feeler gauge, the proper method is to adjust it so that a blade of the proper size is a light drag when pulled through.

It is important that feeler gauges be properly cared for and kept out of the weather as much as possible. Long exposure will cause corrosion to build up on the blade, which will affect the thickness. It may be impossible to remove this corrosion without abrasive methods, which is, of course, not practical since this will also affect blade thickness.

If your tools sits out in a garage, it may be profitable to spray your feeler gauge with a demoisturizing agent from time to time in order to protect the blades. Naturally, make sure you clean off any blade thoroughly before using it.

Soldering Gun

Soldering is a quick, efficient method of joining metals permanently. Everyone who has the occasion to make electrical repairs should know how to solder. Electrical connections that are soldered are far less likely to come apart and will conduct electricity far better than connections that are only "pig-tailed" together.

The most popular (and preferred) method

Soldering irons are available in many sizes and wattage ratings

of soldering is with an electric soldering gun. Soldering irons are available in many sizes and wattage ratings. Irons with high wattage ratings deliver higher temperatures and recover lost heat faster. A small soldering iron rated for no more than 50 watts is recommended for home use, especially on electrical projects where excess heat can damage the components being soldered.

There are 3 ingredients necessary for successful soldering—proper flux, good solder and sufficient heat.

FLUX

A soldering flux is necessary to clean the metal of tarnish, prepare it for soldering and to enable the solder to spread into tiny crevices. When soldering electrical work, always use a resin flux or resin core solder, which is non-corrosive and will not attract moisture once the job is finished. Other types of flux (acid-core) will only leave a residue that will attract moisture causing the wires to corrode.

GOOD SOLDER

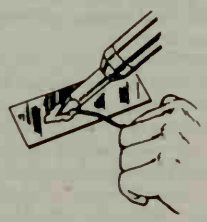
Tin is a unique metal. In a molten state, it dissolves and alloys easily with many metals and has a low melting point. Solder is made by mixing tin (which is very expensive) with lead (which is very inexpensive). The most common proportions are 40/60, 50/50 and 60/40, the percentage of tin always being listed first.

Low priced solders often contain less tin and this makes them very difficult for a beginner to use, because more heat is required to melt the solder. A common solder is 40/60 which is well suited for all-around general use, but 60/40 melts easier, has more tin for a better joint and is preferred for electrical work.

SUFFICIENT HEAT

Successful soldering requires enough heat to raise the areas of the metals to be joined to a temperature that will melt the solder, usually somewhere around 360–460°F., depending on the tin content of the solder. Contrary to popular belief, the purpose of the soldering iron is not to melt the solder itself, but to heat the parts being soldered to a temperature high enough to melt solder when it is touched to the work. Melting flux-cored solder on the soldering iron will usually destroy the effectiveness of the flux.

How to Solder

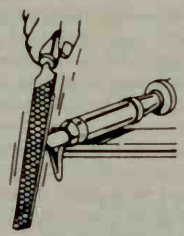


1. Soldering tips are made of copper for good heat conductance, but must be "tinned" regularly for quick transference of heat to the project and to prevent the solder from sticking to the iron. To "tin" the iron, simply heat it and touch flux-cored solder to the tip, the solder will flow over the tip. Wipe the excess off with a rag.

2. After some use, the tip may become pitted. If so, simply dress the tip smooth with a smooth file and "tin" the tip again.

3. An old saying holds that "metals well-cleaned are half soldered." Flux-cored solder will remove oxides, but rust, bits of insulation and oil or grease must be removed with a wire brush or emergy cloth.

4. For maximum strength in soldered parts, the joint must start off clean and tight. Weak joints will result in gaps too wide for the solder to bridge.



5. If a separate soldering flux is used, it should be brushed or swabbed on only those areas that are to be soldered. Most solders contain a core of flux and separate fluxing is unnecessary.

Test Equipment

Continuity lights and *test lights* are very handy to have for any number of tasks. In addition to tracing electrical troubles such as shorts and open circuits, either can be used for static (engine off) ignition timing, for battery-ignition motorcycles.

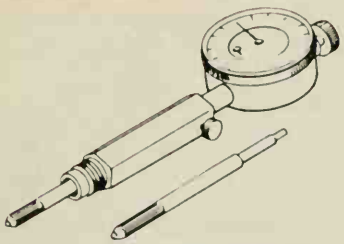
A test light need be nothing more than a small bulb of the same voltage as your motorcycle's electrical system (6 or 12V) with two leads attached. Alligator clips are necessary if you intend to time the bike with this light, since your hands will be otherwise occupied during this procedure.

Simple continuity light

Timing light with a self-contained power source

A continuity light can be rigged in a number of ways. Basically, it is a bulb wired in series with a battery. You can use a flashlight battery and bulb providing the bulb is matched to the battery voltage.

With the simpler test light, ignition can be checked on battery-ignition motorcycles by connecting one light lead to ground on the engine case, and the other to the breaker point primary terminal or spring. The motorcycle's ignition must be *on*. When the points open, the bulb will go *on*.



A continuity light used for ignition timing is connected in the same manner as the test light. The difference is that the bike's ignition must be turned *off* when setting the timing. When the points open, the continuity light bulb will go *off*.

On many motorcycles, it is preferable to set the ignition timing *dynamically*, that is, with the engine running. For this job, a stroboscopic timing light is necessary, and suitable strobes through a wide range of prices can be obtained almost anywhere.

Neither of these methods may work on a large number of magneto-ignition motorcycles, however, due to the characteristics of magneto construction. For many of these machines, the moment of point opening must be checked with an *ohmmeter*. Yamaha dealers sell a sensitive ohmmeter called a "Points Checker" for this very purpose.

In addition, a dial indicator may be needed for your bike. When setting the ignition timing it is necessary to know just where the picton is at the time the points open. On many battery-ignition machines, this is indicated by top dead center and firing marks on the alternator rotor. On some magneto-ignition bikes, however, this is not the case, and a dial gauge is needed.

A *voltmeter* is used to measure the difference in electrical "pressure" between two points in a circuit. Just as water pressure is measured in pounds per square inch, electrical pressure is measured in volts. When a voltmeter's two probes are placed on two "live" portions of an electrical circuit with different electrical pressures, current will

A dial gauge for finding piston position

flow through the voltmeter and produce a reading which indicates the difference in electrical pressure between the two parts of the circuit. An ohmmeter differs from a voltmeter in that it incorporates its own source of power so that a standard voltage is always presednt. An *ohmmeter* is connected in the same way as a voltmeter, but since it is self-powered, all the power in the circuit should be off and the portion of the circuit to be measured contacted at either end by the probes of the meter. Remember that a voltmeter is measuring volts or electrical pressure, while an ohmmeter is measuring ohms, or circuit resistance. Volt/ohmmeters are only useful if you have some knowledge of electricity and of course have the factory specifications for whatever you are testing. It does you no good to know that a certain circuit has, say, twelve volts, unless you know what the factory specification for that circuit is. They are not used very often but are handy in certain situations.

Miscellaneous

There are a few other items which will make life a little easier when you are working on the bike. A *points file* is used to remove burned marks or flash-over from points surfaces and can also be used to square off spark plug electrodes.

A *wire brush* is useful for cleaning plugs, removing corrosion from bolt threads, etc.

You should also have a selection of emery cloth, sandpaper, and the like, as well as penetrating oil, parts-easing fluid, spray solvents, and thread-locking compound (non-permanent).

Of course, we cannot possibly list *all* of the tools you will ever need, but you may eventually run into the need for most of the ones mentioned above.

ORDERING PARTS

We recommend that you replace any necessary parts on your motorcycle with original factory equipment. This is the safest course. Other parts may differ slightly in quality, and using them may void your warranty. In addition, purchasing parts from an authorized dealer of your motorcycle will ensure that you get the right part for your bike.

When ordering parts, always provide the model, year, and engine and frame numbers where necessary.

Compare the new part with the old one where possible before trying to install it. Then, if a mistake has been made, you can return the incorrect item at no cost.

Be careful when buying electrical components, especially expensive charging system items such as regulators or rectifiers, or the even more expensive electronic ignition units. Almost all dealers and parts outlets have a standing policy against any returns or exchanges on electrical parts. The reason for this is that these items can be easily damaged or destroyed by such a simple mistake as reversing two connecting wires, or by another defective part in the circuit. There is usually no way of telling if the component is ruined just by looking at it either.

Buying Used Parts

Replacing worn or broken parts of your machine with acceptable used parts from a wreck, salvage yard, or other source is certainly a simple way to save money, but you had better know what you are doing before you try it.

Parts which are subject to normal wear such as pistons or clutch plates should never be purchased to replace what you have no matter how good they look. The same goes for bearings or bushings. They will only continue to wear at the normal rate, and before you know it you will be doing the same job again.

Some parts, however, do not normally wear out in the short run, and if you have had a spill, accident damage, or a freak occurrence such as a hole punched in the crankcase, some used items may cut the cost of repair significantly.

Before even considering used parts, first find out where they come from. A set of carburetors from a motorcycle which was wrecked in a collision may be a good buy, but carburetors from a motorcycle with a blown engine may not be. Did the carburetors themselves cause engine failure because of air leaks, bad casting, or some other hidden defect? You should ask yourself questions such as this before you commit yourself.

Rolling chassis components such as forks, shocks, wheels, and brakes often make good purchases since new items are very expensive, and the condition of the used parts will probably be evident at first examination.

Used electrical components are a very chancy proposition. It is impossible to determine how long they have been in service, or whether failure is imminent.

Major items, such as cylinder heads, can cost enormous sums if purchased new, so buying a used one might be considered. The part must be examined closely, however, and it helps, once again, to know where it came from and what kind of service it has seen. A part like a cylinder head will have to be reconditioned in any case, so barring unusual damage such as cracks in the casting or battered valve seats, you can save money if you are cautious. If you do not know what to look for in an engine component, however, it is best not to take the chance. Always remember that, aside from the money you invest in your bike, every part on the machine affects your personal safety when you ride. What kind of price can you put on that?

Another point to keep in mind when buying used parts is applicability. Be sure that the part comes from your exact model and year. Manufacturers very often make minor changes in parts from year to year or between similar models. Even if the differences are not immediately apparent, they may be very significant especially when, as is almost always the case, the part you are replacing has to work in close conjunction with another part. Even a minor difference here may cause a malfunction.

OILS AND ADDITIVES

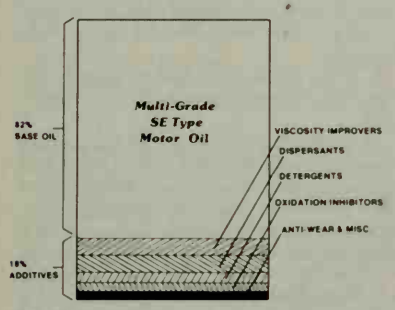
The Functions of Engine Oil

What does oil do in your engine? If you answered "lubricate," you're only partially right. While oil is primarily a lubricant, it also performs a number of other functions which are vital to the life and performance of your engine.

In addition to being a lubricant, oil also dissipates heat and makes parts run cooler; it helps reduce engine noise; it combats rust and corrosion of metal surfaces; it acts as a seal for pistons, rings, and cylinder walls; it combines with the oil filter to remove foreign substances from the engine.

Types of Engine Oil

Engine oil service classifications have been provided by the American Petroleum Institute and include "S" (normal gasoline engine use) and "C" (commercial and fleet) applications. The following chart compares the latest API oil classification with those previously used:



Oil Viscosity

In addition to meeting the SE or SF classification of the American Petroleum Institute, your oil should be of a viscosity suitable for the outside temperature in which you'll be driving.

Oil must be thin enough to get between the close-tolerance moving parts it must lu-

bricate. Once there, it must be thick enough to separate them with a slippery oil film. If the oil is too thin, it won't separate the parts; if it's too thick, it can't squeeze between them in the first place—either way, excess friction and wear takes place. To complicate matters, cold-morning starts require a thin oil to reduce engine resistance, while high-speed driving requires a thick oil which can lubricate vital engine parts at temperatures up to 250° F.

"SE" oil composition

According to the Society of Automotive Engineers' viscosity classification system, an oil with a high viscosity number (e.g., 40) will be thicker than one with a lower number (e.g., 10W). The "W" in 10W indicates that the oil is desirable for use in winter driving. Through the use of special additives, multiple-viscosity oils are available to combine easy starting at cold temperatures with engine protection at turnpike speeds. For example, a 10W-40 oil will have the viscosity of a 10W oil when the engine is cold and that of a 40 oil when the engine is warm. The use of such an oil will decrease engine resistance and improve your miles per gallon during short trips in which the oil doesn't have a chance to warm up.

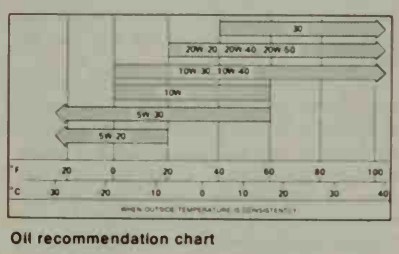
Some of the more popular multiple-viscosity oils are 5W-20, 5W-30, 10W-30, 10W-40, 20W-40, 20W-50, and 10W-50. In general, a 5W-20 or 5W-30 oil is suitable for temperatures below 0°F, 10W-30 or 10W-40 whenever the lowest temperature expected is 0° F., and 20W-40 whenever the lowest temperature expected is 32° F. However, consult your owner's manual or the "Recommended Lubricants" chart at the end of each "Maintenance" section for the recommended viscosity range for your motorcycle and the outside temperature in which it operates.

Additives

A high-quality engine oil will include a number of chemical compounds known as additives. These are blended in at the refinery and fall into the following categories.

Pour Point Depressants help cold starting by making the oil flow more easily at low temperatures. Otherwise, the oil would tend to be a waxy substance just when you need it the most.

Oxidation and Bearing Corrosion Inhibitors help to prevent the formation of gummy deposits which can take place when engine oil oxidizes under high temperatures. In addition, these inhibitors place a protective coating on sensitive bearing metals, which would otherwise be attacked by the chemicals formed by oil oxidation.



Rust and Corrosion Inhibitors protect against water and acids formed by the combustion process. Water is physically separated from the metal parts vulnerable to rust, and corrosive acids are neutralized by alkaline chemicals. The neutralization of combustion acids is an important key to long engine life.

Detergents and Dispersants use teamwork. Detergents clean up the products of normal combustion and oxidation while dispersants keep them suspended until they can be removed by means of the filter or an oil change.

Foam Inhibitors prevent the tiny air bubbles which can be caused by fast-moving engine parts whipping air into the oil. Foam can also occur when the oil level falls too low and the oil pump begins sucking up air instead of oil (like when the kids finish a milkshake). Without foam inhibitors, these tiny air bubbles would cause hydraulic valve lifters to collapse and reduce engine performance and economy significantly.

Viscosity Index Improvers reduce the rate at which an oil thins out when the temperature climbs. These additives are what makes multiple-viscosity oils possible. Without them, a single-weight oil which permitted easy starting on a cold morning might thin out and cause you to lose your engine on a hot afternoon. If you use a multiple-viscosity oil, it's this additive that helps your gas mileage during those short trips in cold weather.

Friction Modifiers and Extreme Pressure additives are valuable in so-called boundary lubrication, where there is metal-to-metal contact due to the absence or breaking down of the oil film between moving parts. Friction modifiers, or anti-wear agents, deposit protective surface films which reduce the friction and heat of metal-to-metal contact. Extreme pressure additives work by reacting chemically with metal surfaces involved in high pressure contact.

Oil recommendation chart

Synthetic Oils

Recently, a number of major oil companies have introduced synthetic oils, which are composed of manmade hydrocarbons instead of petroleum based hydrocarbons. There are quite a few claims being made for synthetic oils, including increased gas mileage, extended oil drain intervals, improved hot and cold weather engine performance, and less wear and tear on engines. Whether or not these claims are true has yet to be decided. One thing is certain, however. Synthetic oil is inexpensive. At prices that range up to three dollars a quart, synthetic oils will have to live up to every one of their claims to be cost-effective but, as long as it has an SE or SF rating, synthetic oil certainly will not harm your engine.

Transmission Lubricants

Four-strokes with transmissions which use a separate oil supply and two-strokes may require special oil for the gears.

Most four-strokes specify SAE 80 or SAE 90 "EP" (extreme pressure) lubricant for this purpose. This is a gear oil viscosity and has nothing to do with motor oil viscosity. For example, an SAE 80W gear oil can have the same viscosity characteristics as an SAE 40 or 50 motor oil.

Two-strokes generally use a lighter oil in their transmissions. This may be 10W-30 or 20W-50 motor oil. Check the "Recommended Lubricants" chart at the end of each "Maintenance" section for the proper oil for your bike.

Drive Box Lubricants

All shaft-drive motorcycles currently in production recommend SAE 90 EP gear lube for the rear drive box. In winter, SAE 80 EP may be used.

Front Fork Oil

Refer to the "Recommended Lubricants" chart included in each "Maintenance" section for fork oil recommendations. Depending on make and model, fork oils may range from ATF (Automatic Transmission Fluid) to SAE 30W motor oil or specially designed fork oils.

NOTE: *When fork capacities are given, the quantities shown always refer to the amount needed in each fork leg.*

Chassis Grease

Chassis grease is generally needed for the swing arm pivot, drum brake cams, exposed pivoting parts, and anywhere else that grease fittings occur.

Other uses include lubrication of speedometer drive boxes, internal lubrication of instrument cables, waterproofing control cables, throttle drums, etc.

There is not much differentiation among chassis lube. Generally, anything that will fit your cartridge-type grease gun should do the job.

Wheel Bearing Grease

Wheel bearing grease should be of the long fiber (high temperature) type, especially for motorcycles with disc brakes.

Bearing grease is also used for steering head bearings.

Disc Brake Fluid

DOT 3 or DOT 4 hydraulic disc brake fluid is recommended for most motorcycles. The SAE standard is J1709. The rating can be found on the can. Any exceptions will be noted in the applicable section.

Drive Chain Lubricant

A good brand of lubricant developed and marketed specifically for motorcycle drive chains is recommended in most cases. Follow the manufacturer's instructions when applying the lube.

Some drive chains now in use have rubber o-rings between the side plates and rollers. These o-rings may be damaged by certain

types of chain lube. For this reason, SAE 90W oil should be used to lubricate the chain. Check the "Recommended Lubricants" chart at the end of the applicable "Maintenance" section for the proper recommendation.

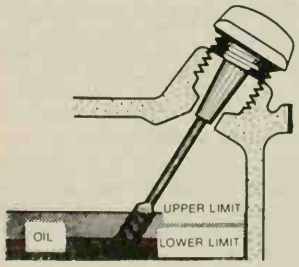
General Lubrication

For control cables, pivoting parts such as kickstands or folding footpegs, etc., light motor oil can be used. Alternatives include graphite or molybdenum disulphide lubricants which are readily available in small dispensers from your dealer or an auto supply store.

ENGINE OIL CHANGES

Oil changes should always be performed according to the recommended intervals, or more frequently under certain circumstances.

An often overlooked fact about oil change intervals is that they depend not only on mileage, but upon *time*, that is, how long the oil has been in the crankcase, regardless of how much the machine has been ridden.

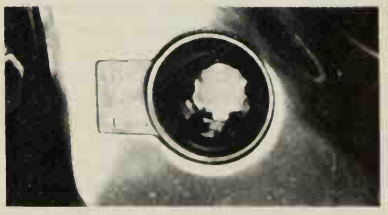


Oil wears out in time and loses its lubricating properties. Gradually the oil begins to be filled with acids from combustion as well as the more widely feared particles of dirt or metal.

As noted previously, oil oxidizes during exposure to air, and this naturally affects its efficiency. Acids get into the oil when the engine is started from cold. While the cylinder walls are not yet at operating temperature, the acids formed by the combustion process may condense on them and then get into the oil. Unless the lubricant is changed, these acids may destroy the oil's lubricating properties in time.

The recommended oil-change interval is based upon normal usage, and should probably be done more frequently if the bike is used under adverse conditions.

These conditions include extended periods of high-speed riding at high air temperatures, operation in an extremely dusty environment, extended periods of stop-and-go riding, extended short hops (such as commuting a short distance), infrequent operation, especially during the winter months, and so on.



The correct oil as recommended by the manufacturer is given in the "Recommended Lubricants" chart at the end of each "Maintenance" section. Note that motor oil service-rated "SE" or "SF" is recommended for all four-strokes. Oil of lesser quality should never be used.

On most bikes, the dipstick should rest on the threads of the inspection hole when checking the level

Maintain the oil level between the upper and lower dipstick marks (A and B)

Oil level sight glass

Most motorcycles are fitted with a dipstick to check the engine or transmission oil level. Some have a level plug. The dipstick or level plug must be the final determination as to whether the level is correct.

When checking any oil level, the engine should be warm, parked on the center stand, and on a level surface. Note that most manufacturer's specify that the dipstick rest on the threads of the dipstick hole when checking the level, although on some models, the dipstick must be threaded all the way into the hole.

On four-stroke motorcycles with a wet-sump lubrication system, oil level is checked at the tank. It is important that machines of this type be run for several minutes before checking the oil level, as the oil has a tendency to seep into the engine while the machine is at rest for any length of time, resulting in a false reading.

When changing oil, the engine should be close to operating temperature. This makes it easier for the oil leaving the engine to carry particulate matter with it. Be sure that all appropriate drain plugs are removed. On dry-sump machines, oil must be drained from both the oil tank and the crankcase.

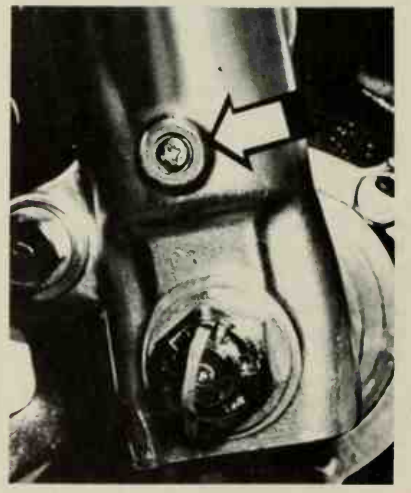
After adding the correct amount of oil, allow the engine to run for a minute or so and recheck the level. Top up if necessary.

The use of oil additives is not specifically recommended by any manufacturer. Some types of additive may cause clutch slippage on machines with a "wet" clutch.

TRANSMISSIONS/DRIVE BOXES

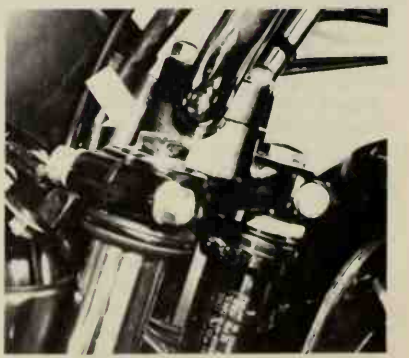
Motorcycles with separate gearboxes and shaft drive bikes with rear wheel drive boxes need oil changes at these points.

In all cases, proper oil level is determined by means of a level plug.



Change the oil when the unit is at operating temperature. After tightening the drain plug securely, refill the unit until the oil just begins to seep out of the level plug hole.

FRONT FORKS



1. Most motorcycle telescopic forks are similar as far as routine maintenance is concerned, using with a drain plug at the lower end of the slider and a filler cap on top of the fork tube.

2. Refer to the individual sections for the type of fork oil recommended for your motorcycle.

Many motorcycles can use ATF (automatic transmission fluid) in the forks. Others take various weights of motor oil. Although it is often possible to change the damping characteristics of the forks by filling them with a different viscosity oil, care must be taken to ensure that the oil you are adding is compatible with that which was previously in the fork. If you are not sure, flush the forks with a solvent before adding the new oil. On almost all motorcycle forks, *some* of the old oil will remain in the fork even if the slider is pumped after the drain plug is removed. This fact should also be taken into consideration when rebuilding forks. Note that many models give two fork capacities: one for routine changes, one for after disassembly of the fork

Front fork oil drain plug

Front fork filler cap

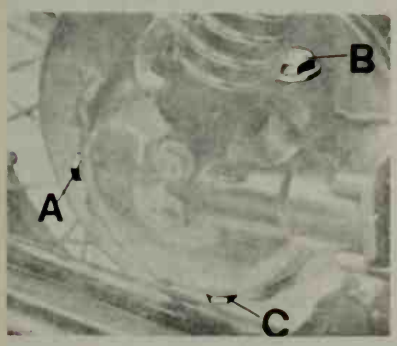
leg. The latter figure is roughly 10% greater than the former.

3. Care must be taken when changing fork oil.

To drain the oil, remove the drain plug from the bottom of the fork slider. On most forks, it will be necessary to pump the slider up and down several times to get it all out.

Inspect the drained oil. If the oil is very dirty, or if it contains water; it is probable that the slider seals are ineffective and should be replaced.

After refitting the drain plugs, remove the filler caps.



CAUTION: *On most forks, removal of both filler caps will allow the forks to collapse, possibly tipping the machine over. Therefore, either support the front wheel off the ground by placing a scissors jack or "sturdy crate beneath the engine (if necessary), or leave one of the filler caps in place while the other is removed.*

4. On some models, special procedures are necessary to remove the filler caps (such as moving the handlebars).

5. Adding oil to the forks is easy on some machines, but not so on others. Sometimes, the internal fork components necessitate that the oil be added very slowly since they impede it as it flows down through the fork leg. On some models it is possible to lift out the fork spring to speed filling.

A plastic baby bottle with the nipple cut off is a handy device for filling fork legs, since these are calibrated in ounces or "cc's."

6. After tightening the filler caps very securely, check fork operation. Check for leaks or seepage around the fork slider seals after several miles of operation. Even a small amount will necessitate replacement of the seals. A coating of grime building up in this area over a period of time is also indicative of ineffective seals.

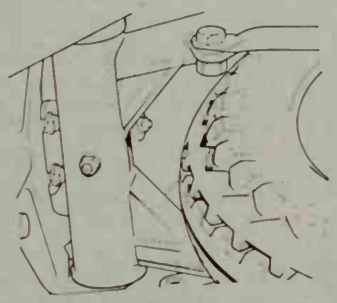
CHASSIS

Most modern motorcycles have only a single grease fitting—at the swing arm pivot.



Chassis grease is injected here to lubricate the swing arm bushings.

On the majority of designs, the fitting is easily visible on the side of the pivot. On others, it is located in the middle of the swing arm pivot tube.

In either case, chassis grease should be applied with a grease gun until some grease appears at both ends of the swing arm. Wipe off the excess grease.

CABLES AND CONTROLS

1. The throttle, clutch and drum brake cables should be lubricated about every 3,000 miles either with a light or medium grade of motor oil or with the newer graphite or molybdenum-based lubricants sold for this purpose.

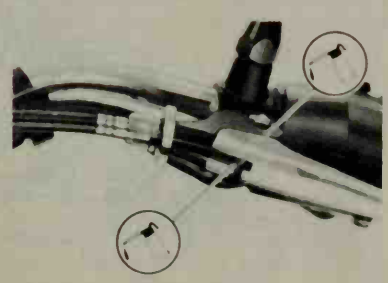
2. Disconnect the cable from the lever or twist-grip and dribble the lubricant down between the inner cable and the sheath until you think the lubricant is coming out of the other end. If you are using motor oil, a few drops of gasoline added to the cable first will make the surface of the cable slicker so that the oil will flow into the cable somewhat faster.

3. After lubricating the cables, apply some chassis grease to the exposed upper portion of each cable, and attempt to get some into the sheath. This will help prevent the entry of dirt and water.

4. A few drops of oil should be applied to the cable fitting in the clutch lever. Lack of lubricant here may cause a snatching feeling when the lever is pulled, due to the cable fitting binding in the lever. Since the lever's hole is on the lower side and hard to lubricate, one solution is to smear the cable fitting with grease before reconnecting it.

5. After fitting the clutch cable to the lever, readjust it, but to keep out water and foreign matter, try to position the slot in the cable adjuster so that it points downward.

6. The throttle twist-grip should be taken apart and the drum lubricated with a lightweight, multi-purpose grease.



CAUTION: *When working on the twist-grip, take care not to disturb the wiring connections in the twist-grip housing.*

7. When assembling the twist-grip, tighten the screws slowly and evenly while operating the throttle to ensure free movement.

8. A few drops of motor oil should be applied to drum brake pedal pivots. At more extended intervals, the drum brake cam should be lubricated with chassis grease. Disassembly of the brake plate will be required.

9. The tachometer and speedometer cables should be disconnected, removed from the sheaths, and smeared with a light coating of chassis grease. This should be done about every 3,000 miles. Use very little of the grease on the portion of the cable closest to the instrument to avoid getting any inside the works.

10. At about 12,000 mile intervals, the speedometer drive mechanism should be lubricated with chassis grease.

DRUM BRAKES

Drum brakes have one point which should receive periodic lubrication, and that is the brake cam or cams which open and close the brake shoes.

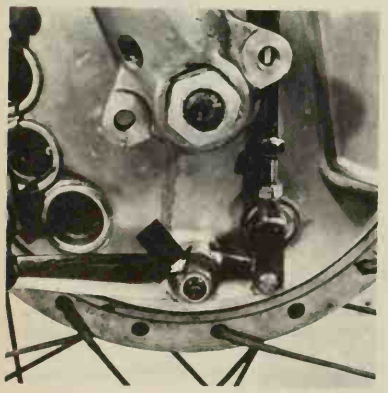
In most cases, the cams ride directly in holes in the aluminum brake plate. They are often protected by dust washers to keep out dirt and water.

To lubricate the cams, remove the wheel from the motorcycle and take out the brake plate.

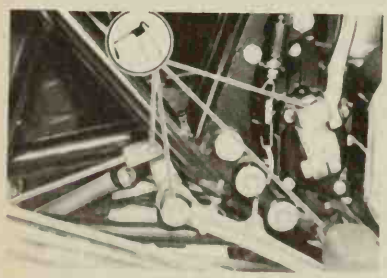
Remove the brake shoes from the plate.

Loosen the brake lever pinch bolt and carefully pry the lever from the splined cam shaft. It might be helpful to punch mark the lever and shaft for position before removal to facilitate reassembly, although on some designs the punch marks are there already.

Remove any dust washers or spacers and tap out the cam shaft.



Removing the brake plate lever



Removing corrosion from the brake cam

Clean the shaft thoroughly in a solvent to remove any old grease. Remove any rust or corrosion with a fine grade of emery paper. Clean out the hole in the brake plate as well.

Before installing the shaft, lubricate it thoroughly with a good grade of chassis grease. Check for free movement of the shaft before assembling the remaining components.

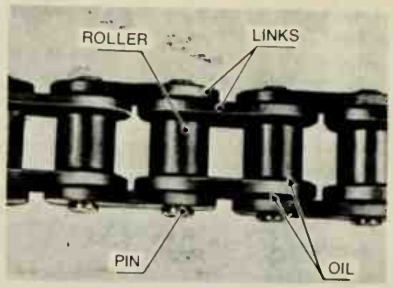
Typical brake cam grease fitting

Brake linkage, footpeg, and kickstarter lubrication points

On some older bikes, the brake cam is fitted with a grease nipple which allows the cam to be lubricated without disassembly. On set-ups like this, the cam nipple should receive no more than one shot of chassis grease from the grease gun.

MOVING PARTS

There are a number of moving parts on the motorcycle which should receive periodic lubrication with motor oil or light grease. These include drum brake rod pivots, folding footpegs, side and center stands, carburetor linkages, brake pedals, and kickstarter pivots.



DRIVE CHAIN LUBRICATION

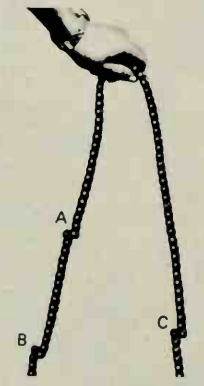
Some models now come with permanently lubricated drive chains, but most do not. Automatic oiling devices found on some models meter engine oil onto the chain while riding, but this is not usually sufficient to keep the chain properly oiled and should not be considered as the last word in chain lubrication.

Refer to the individual "Maintenance" section for the proper chain lubricant for your machine. Most motorcycles should have a special lubricant developed specifically for drive chains applied at regular intervals. These can be purchased at any shop. Note, however, that a number of late model machines are equipped with drive chains which incorporate rubber O-rings between the chain plates which serve as a kind of seal. Some of these O-rings can be damaged by synthetic or petroleum-based chain lubes. In this case, the manufacturer recommends lubricating the chain with 80 or 90W oil. The recommended lubricant for your machine can be found in the "Recommended Lubricants" chart of the applicable section.

Frequency of lubrication is dependent upon the type of lubricant used, riding habits, average speeds, weather conditions, and so on.

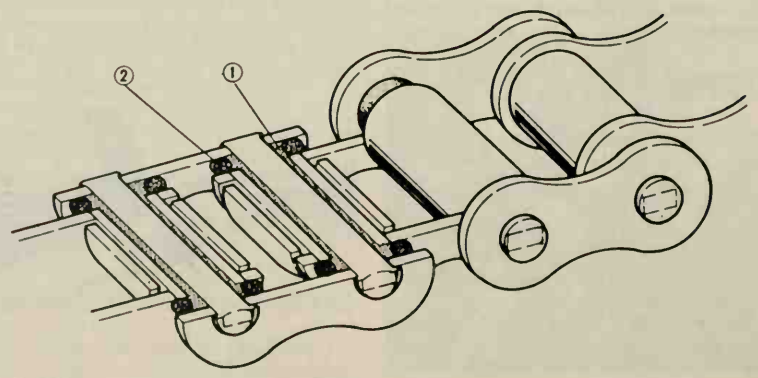
The rider should check chain condition frequently until he or she finds the maintenance interval compatible with his or her riding style. As in the case of engine oil, maintenance will be necessary at shorter intervals if the chain is subjected to severe use: high speeds, off-road riding, jack-rabbit acceleration, etc.

Drive chain lubrication points



Many riders find that an application of chain lube every 300 miles or so gives satisfactory chain life.

When applying a chain lube, be sure to follow the manufacturer's instructions for use. Many lubes are dispensed in a very fluid state. This facilitates their penetration into the chain. In a few minutes they become thick and sticky, enabling them to adhere to the chain as it spins around the sprockets while riding.



When applying the lubricant, direct it towards the edges of the chain plates so it will reach the pins beneath the rollers.

At extended intervals, about every 2000 miles, the chain should be removed from the motorcycle for cleaning.

NOTE: *Models with endless chains will require a special tool to break the chain. On all models, removal and installation of the masterlink spring clip should be done with a pliers—not a screwdriver—to avoid deforming the spring clip.*

Check for kinked or frozen links (A,B,C)

Drive chain lubricant (1) and sealing O-rings (2)

Install masterlink spring clips so that the closed end is facing the direction of chain rotation

Having an old chain on hand makes chain removal somewhat simpler, since the old chain can be attached to one end of the chain on the bike and pulled through over the engine sprocket, so that it is not necessary to remove the sprocket cover or other components.

Remove heavy deposits of dirt and grease with a stiff brush and solvent. Then soak the chain for several hours in a light motor oil. Hang it up to drain.

Check that each chain link can pivot freely. If there are any kinked or binding links which cannot be freed, or if the chain is rusted or has suffered damage from corrosion (such as might happen if it is touched by acid from an incorrectly routed battery overflow tube), replace it.

After cleaning the chain, refit it to the machine, lubricate it in the usual way, and adjust the tension.

When joining the chain, note the following points: models which use an endless type chain will require a new masterlink. On other models, the masterlink may be reused if in good condition. Also, check the condition of the masterlink spring clip. Be sure to install the spring clip with the closed end facing the direction of chain rotation. Also, if the clip is "sprung," the concave side must face the chain.

NOTE: *When washing the machine, especially at high-pressure car washes, keep water and detergents off the chain if possible. Never use high-pressure spray units to remove grease or dirt from the chain. This may damage O-rings on sealed chains or will allow water to get between the pins and rollers on other types of chain.*

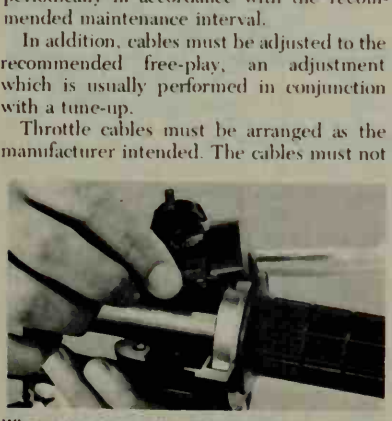
ROUTINE ADJUSTMENTS

CARBURETOR CONTROLS

One often-overlooked cause of poor fuel system operation can be found in the throttle controls: twist-grip, cables, and the linkage arrangements found on multi-carburetor motorcycles.

Proper lubrication of the carburetor controls is essential.

Twist-grips are usually of the split type in which the drum is contained in a two-piece housing. The housing top half can be removed for lubrication. Since many machines incorporate various electrical switches in the twist-grip, exercise care when removing to avoid damage to wiring and connections. Use a light grease in the throttle twist-grip. Apply some lubricant to the part of the grip which contacts the handlebar to ensure smooth movement. When putting the housing back together, note that on most motorcycles, there is a locating pin somewhere on the twist-grip to prevent it from rotating around the handlebar. This pin fits into a hole in the handlebar. Be sure it is engaged before tightening the housing.



When installing the top of the housing, tighten the fasteners slowly and evenly, checking for free throttle movement as you go along.

Throttle cables are arranged in many ways depending on whether the engine is a two or four-stroke, single, twin, or multi, and so on.

All throttle cables should be lubricated periodically in accordance with the recommended maintenance interval.

In addition, cables must be adjusted to the recommended free-play, an adjustment which is usually performed in conjunction with a tune-up.

Throttle cables must be arranged as the manufacturer intended. The cables must not be bent sharply or kinked anywhere along their length. Ensure that the cables are clipped to the frame only at those points determined by the factory. Removal and installation of the gas tank is one instance in which the cable(s) may be disturbed.

When separating the twist-grip, be careful of the electrical wiring

Check that cables are long enough, especially if new ones have been installed, or handlebars changed. With the engine idling, turn the handlebars from lock-to-lock. Any rise in the idle speed indicates that the cables are either too short, improperly adjusted, or are improperly installed.

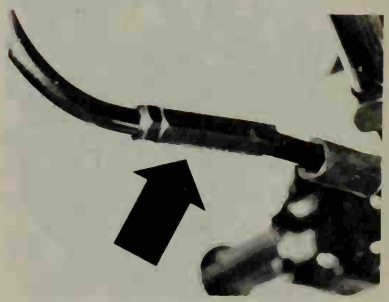
On some motorcycles, especially multicylinder ones, the throttle cables must be routed in specific ways over or under the top frame tubes. Altering this arrangement even in a seemingly minor fashion can cause improper operation. Memorize or make a sketch of the original cable routes before any work is done on the system.

Throttle linkages at the carburetors, such as the pulley arrangements now in wide use, are in most cases best left alone. Some of these linkages have grease fittings which should be lubricated with a light-weight grease at intervals recommended by the manufacturer. Systems of this sort also have the adjustments for throttle slide synchronization, and should therefore be approached with caution, unless you have the proper vacuum gauges to synchronize the slides.

Throttle slides must snap closed from any position except in those rare instances in which the linkage is the non-return type.

Pulley linkages as found on many machines are usually not prone to trouble in this regard. If the throttle slide(s) will not close when the twist-grip is released, first check that the tensioner sometimes fitted to the twist-grip for touring is not in play. Next, check cable lubrication. Inner cables which are sharply bent or kinked can cause the slide(s) to hang up.

Also, check the condition of the inner cable. A cable which is frayed or has even a single broken strand must be replaced at once.



The most common troublespot for throttle cables is at the twist-grip. Since on most motorcycles the cable is bent around the throttle drum when the twist-grip is turned, metal fatigue is only natural and the cable will eventually suffer one or more broken strands at this point. A broken strand can seize in the cable housing making it impossible to close the throttle slide(s). The frequency of cable damage at the twist-grip is dependent to some extent upon the diameter of the drum. A cable which must be bent around a small diameter drum will be more likely to break eventually than one which is not bent to such a great degree. Some machines which suffer frequent cable failure at this point may benefit from the installation of a "quick throttle," which has a large diameter drum.

Another problem which might cause control malfunction is seizing of the slide in the carburetor. Although relatively rare, this can happen on some models. Especially prone to this phenomenon are carburetors which are bolted to their manifolds with a flange. Uneven tightening or overtightening of the mounting nuts or bolts can warp the carburetor body and cause the slide to stick.

On carburetors of this sort, it is sometimes helpful to install the complete slide assembly with carburetor cap in the carb before bolting the unit to the manifold. Constantly operating the slide while tightening the fasteners is recommended. If the slide sticks suddenly, the nuts or bolts are either over-tight, or the carburetor body is warped. This presents a problem, since the fasteners must be relatively tight to form an effective seal at the manifold. If the body is warped, it should be replaced.

Adjust the throttle cable adjuster at the twist-grip so that the throttle has about 10–15° of free rotation before the slides begin to open.

After making this adjustment, start the engine and let it idle while turning the front forks from lock-to-lock. There should be no change in the idle speed. If there is, the cable is too tightly adjusted or is misrouted.

Throttle cable adjuster

HEADLIGHT ADJUSTMENT

The adjustment procedure is similar for all motorcycles.

1. Set the machine about 25 feet away from and perpendicular to a wall, preferably of a color which reflects light well.

The bike should be on its wheels, with a rider putting his weight on the seat as he would when riding.

2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.

3. Vertical adjustment is made by loosening the headlight shell mounting bolts slightly and pivoting the shell up or down.

4. For lateral adjustment, most makes have an adjusting screw at one side or the other.

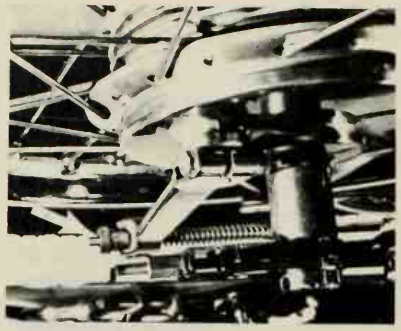
BRAKES

Drum Brakes



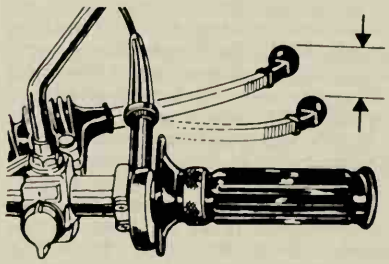
1. Drum brakes are operated by either cable or rod. In most cases, front brakes have cable adjusters at the brake plate and at the hand lever. Rear brakes usually have an adjuster at the brake plate.

Generally, brake adjustment should be maintained so that the brake hand lever or brake pedal has about 1 in. of movement before the linings contact the drum.

In the case of rod-operated rear brakes, this adjustment should be made with the machine off the stands and with a rider sitting on it. The reason for this is that the movement of the swing arm may vary the distance between the brake cam and the pedal pivot, thereby changing the brake adjustment as the machine is operated.

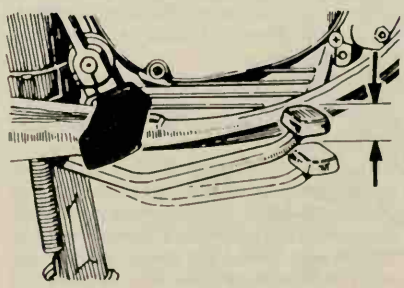
Adjusting the brake at the brake plate

Rear brake adjusting nut



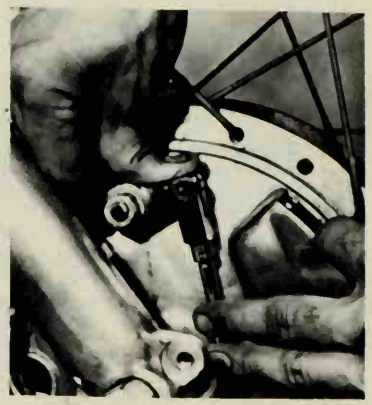
2. On front brakes, the adjustment is usually made at the brake plate, with fine adjustments made at the hand lever.

3. Twin-leading shoe brakes are fitted with a linkage connecting the two cams, and the linkage may not need routine adjustment unless the brake plate has been disassembled or new shoes have been fitted. One type of the linkage has both brake levers connected with a cable and the levers are pulled together when the brake is applied. This type is self-adjusting.



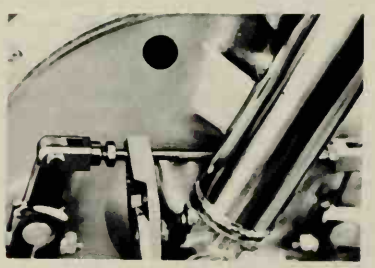
A more common method is to have the brake cable connected to one brake level, the remaining lever being connected to the first by means of a rod and clevises. The rod is usually threaded and means of varying the length of the rod to make an adjustment is possible.

This is done in one of two ways, depending upon how the rod is attached.

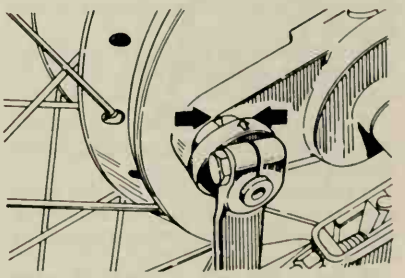


To check the adjustment, disconnect the rod at the main brake lever. There is usually a retaining clip or cotter pin at the clevis pin. Apply the brake hand lever until the shoe contacts the drum. Holding this position, apply the secondary brake lever with your hand until that shoe contacts the drum. The clevis holes should line up at this point. If they do not, lengthen or shorten the brake rod so that the holes align.

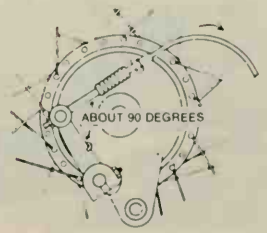
The brake lever should have about 1 inch of movement before the linings contact the drum



The brake pedal should have about 1 inch of movement before the linings contact the drum



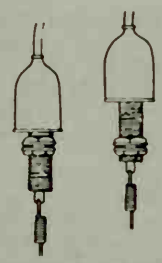
When the brake hand lever is applied so that one brake shoe fully contacts the drum, pushing the other shoe's lever until it too is in contact should result in the alignment of the lever and clevis holes, If not, the brake linkage is improperly adjusted



4. Brake lining wear on newer models can be determined by means of the wear indicator pointer fitted to the brake lever on the hub. If the pointer lines up with the red slash mark when the brake pedal is fully applied, the linings are worn as far as possible for effective braking and should now be replaced.

Adjusting the brake rod

Brake wear indicator marks



With the brake applied, the angle between the lever and cable or rod should be about 90

5. On older models, observe the angle formed by the brake lever on the hub and the brake rod or cable when the brake is fully applied. When the lever and rod or cable form an angle greater than 90°, the shoes should be checked for wear as they probably are worn to the point of needing replacement.

Brake Light Switches

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch and adjuster nut are mounted on a slotted bracket. The rear switch is adjusted by holding the switch and turning the adjuster not to effect adjustment. Moving the switch upon the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Do not turn the switch to effect adjustment as the wires will become twisted and may break. Generally, the brake light should come on just as the linings contact the drum.

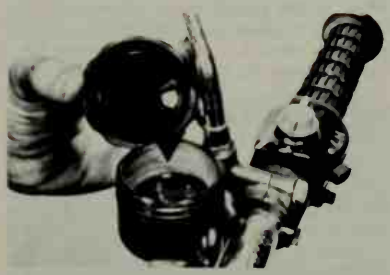
Disc Brakes

1. Disc brake systems need little routine maintenance other than an occasional check on pad wear and fluid level.

2. Pads should be replaced when they are worn to the limit lines. These are fitted to most types of disc brakes. Other types will have tab-type wear indicators. On others, the manufacturer will specify minimum pad thickness.

3. The master cylinder fluid level is usually inscribed on the master cylinder. The fluid level may drop slightly over a period of time as the pads wear, but this drop will be slight. Do not top up a master cylinder reservoir whose level has dropped slightly due to pad wear, since the level will return to the normal level when new pads are fitted. An exception, of course, will be made if braking effectiveness is reduced due to a low level.



Brake pad inspection slot

4. Brake pedal or hand lever travel should be about 1 in. measured at the end of the pedal or lever—the same as for drum brakes. On some systems, there is an adjustment for lever travel. Once properly set, no readjustment should be necessary. If lever travel becomes excessive, the system should be checked over.

5. Periodically check condition of hoses and lines. Be sure that all hoses are arranged as the manufacturer intended, and are properly mounted. Check for abrasion damage. Check banjo fittings for signs of seepage.

CAUTION: *Working with brake fluid requires special precautions. Refer to the "Chassis" section following for information.*

CLUTCH

Unsatisfactorily rough action of the clutch hand lever is almost always due to improper lubrication of the hand lever, clutch cable, or release mechanism.

Like all control cables, the clutch cable must be free of sharp bends or kinks along its route. If lever pull is hard, check this first.

Always keep the cable well lubricated by dribbling oil or a special cable lubricant between cable and sheath. Be sure that the lever itself has a well-lubricated pivot. Also, check the fit of the cable end in the lever. The cable end must turn slightly when the lever is pulled toward the handgrip, and if it cannot do so, lever action will be stiff and cable life short. An uneven or snatching feeling when the lever is pulled towards the handgrip is often due to the cable end fitting binding in the lever. This can usually be remedied by thoroughly lubricating the cable end fitting. If this does not work, the lever cut-out can be enlarged slightly with a file so that the cable end fitting is free to rotate in it.

The release mechanism on some machines requires occasional service. On some Hondas, the mechanism is fitted with a grease fitting easily accessible on the engine case. One or two shots of chassis grease every year or so should suffice here.

On some other makes no grease nipple is fitted, and the release mechanism must be removed for service. This is especially true of those makes in which the release mechanism is installed in the engine sprocket cover. In this location the mechanism can get very dirty due to its exposure, and rough clutch action will be the result.

The clutch cable on almost all designs has an adjuster fitted at the clutch hand lever. Clutch cable adjustment must always be maintained at the proper specification. If the cable has insufficient free-play, the clutch will slip and rapidly burn out. If it has too much play, the clutch will not disengage completely, resulting in hard shifting and creeping at stops.

Use the adjuster at the hand lever to maintain the correct amount of cable slack. The

Clutch cable free-play (arrow) should be 2-3 mm (0.08–0.12 in.)

Typical clutch adjusting screw and locknut

clutch lever should be able to be moved 2–3 mm (0.08–0.12 in.) measured between the lever and the lever holder before the clutch begins to disengage.

If clutch operation is not satisfactory after making this adjustment, the clutch itself must probably be adjusted.

Note that there is a large difference between adjusting the *cable*, and adjusting the *clutch*. Cable adjustment is not the way to get rid of clutch maladies. On the other hand, no amount of clutch adjustment will compensate for an incorrectly adjusted cable.

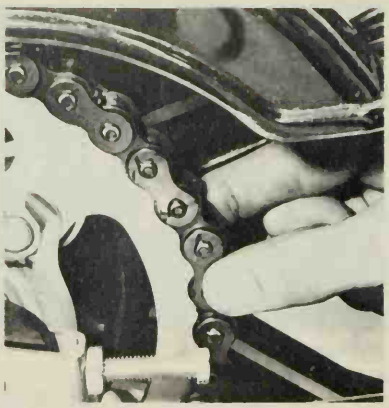
On most bikes, the clutch is adjusted by means of a screw which bears against the clutch pushrod. To adjust this type of set-up, first run down the cable adjuster or adjusters to give as much slack as possible in the cable.

Next, loosen the clutch adjuster locknut and back it off several turns.

Carefully screw the adjuster *in* until resistance is felt. This resistance will be the adjuster bearing against the pushrod(s) which in turn bear against the clutch pressure plate.

Back the adjuster off ½–¾ turns and tighten the locknut. Adjust the cable to give the proper amount of free-play.

CHAIN AND SPROCKETS



1. First make a visual inspection of the chain and its sprockets. If the chain is rust red in color, it has probably suffered too long without proper lubrication, and should be replaced as the damage done to the pin bushings (which you cannot see) is already beyond repair. The chain must also be replaced if it has any broken or cracked rollers.

If the chain is very dirty, covered with grease and dirt, it should be removed and cleaned.

2. Check the battery overflow tube, and ensure that it has been so routed as to avoid the chain completely. White deposits on the links is a sign that sulfuric acid from the battery has come in contact with the chain. If this has happened, the acid has probably damaged one or more of the links. This will weaken them to the point where the chain can no longer be trusted. The chain should be replaced immediately.

3. After lubrication and adjustment road test the bike to check chain operation. If the motorcycle vibrates at intervals, it could be that the chain is too tight, or that one of the sprockets is warped or worn. If the chain slaps the chainguard or swing arm, it is too loose and must be adjusted. Another symptom of a badly adjusted or worn chain or sprockets is noise while coasting. This can be checked by simply rolling the bike down hill for a short distance.

If the chain slaps the chainguard or swing arm, it is too loose and must be adjusted. Another symptom of a badly adjusted or worn chain or sprockets is noise while coasting. This can be checked by simply rolling the bike down hill for a short distance.

Attempt to pull the chain off the sprocket to check for wear

4. The drive chain slack is the total up and down movement of the chain measured at a point midway between the sprockets. The specifications may differ for various machines, but is usually about 20mm (¾ in.).

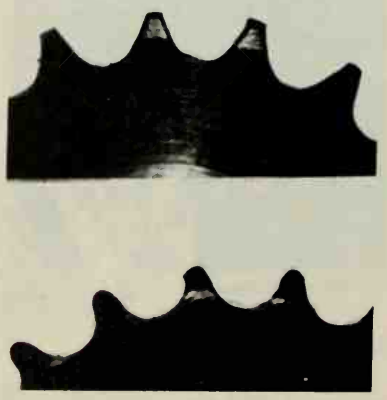
5. Conditions under which the chain slack is measured differ from make to make. Some manufacturer's specify that the machine be on the center stand with the rear wheel off the ground, while others state that the slack is measured with the weight of a rider on the bike. Refer to the individual model section for the correct method.

6. On all machines, however, it is imperative that the chain be clean and well lubricated before checking slack.

7. The chain must be checked for tight spots before making this adjustment. Rotate the wheel slowly and note any variances in chain tension. If the tension varies greatly, it is probable that the chain or the sprockets are worn to the point of replacement. If a tight spot is found, make a mark on the rear sprocket relative to some fixed point. Continue to rotate the wheel. If the chain becomes tight each time the sprocket mark passes the point you chose, the sprocket is warped and should be replaced. If there is no relation between the periods of chain tightness and the rotation of the sprocket, chances are that the chain itself is the problem.

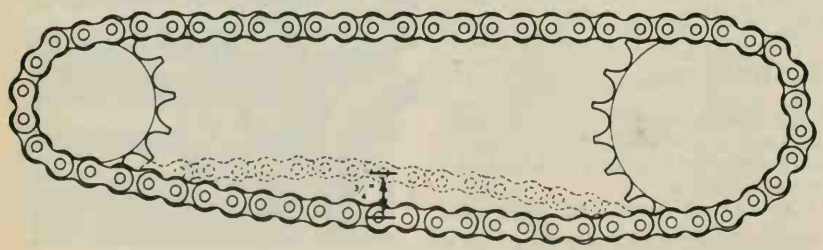
8. Although a chain with a tight spot must soon be replaced, if it must remain in service for a period of time be sure to adjust the chain tension to the given specification at the tight spot. This will probably mean that the chain will have some very loose spots at which it may slap and hit the chainguard, but the potential of breaking the chain will be somewhat reduced.

9. After adjusting the chain to the manufacturer's specification, check for wear by attempting to pull the chain off the rear wheel sprocket. If you can see more than ½ of the sprocket tooth at the point this is done, the chain is worn and should be replaced as soon as possible.



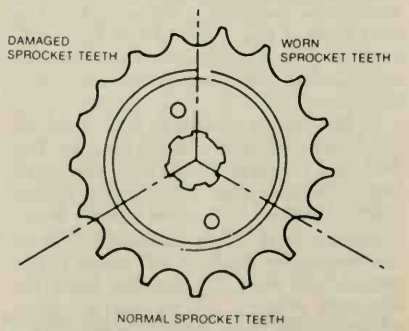
10. Other methods of checking the chain for wear involve first removing it from the machine. Stretch the chain out to its full length and measure it. Then compress the links so that the chain is as short as possible, but not bent. Measure the chain again. If the difference between the two measurements amounts to more than ¼ in. per foot of chain, or more than 3% of its total length, the chain should be replaced.

11. In the event of a worn chain, the sprockets should be inspected closely. A worn chain can ruin sprockets, and conversely, worn sprockets will quickly wear out a new chain.



Check that the sprocket teeth are not hooked. This is the most common sign of a damaged sprocket. Also check for wear on the edges and sides of the teeth. If possible, remove the sprockets, place them on a flat surface and check for warpage. The sprockets must be perfectly flat.

If one of the sprockets is worn, it is recommended that both of them be replaced.



12. Proper alignment of the rear wheel is very important for handling and for chain and sprocket life. Most motorcycles have axle alignment marks on the swing arm, and care should be taken when adjusting the chain that the index on the adjuster are lined up

Normal (top) and worn sprocket

Chain play should be measured in the middle of the lower run

Sprocket wear patterns

with the same mark on both sides of the wheel.

If such alignment marks are not fitted, it is possible to align the wheel by "eyeballing" it using the front wheel as a reference. Alternately, if there is not too much in the way, you can measure the distance from the swing arm pivot to the center of the axle and make sure it is the same on both sides.

TWO-STROKE DECARBONIZATION

Decarbonization of the top end of two-stroke engines is a very important service which must be done regularly and thoroughly if engine performance is to be maintained. The cylinder head, piston crown, exhaust port, and exhaust system should all be cleaned at the same time.

Each manufacturer has their own recommended service interval for decarbonization, but this is only an approximation since the amount of carbon build-up on engine components is largely dependent upon carburetor settings, the type of two-stroke oil used, riding habits, and several other factors.

A substantial loss of power, especially in the higher gears, is usually a signal that decarbonization is necessary. Also, the presence of carbon deposits 1/16 in. or more in depth on the exhaust system baffles indicates that service is required.

To perform a routine decarbonization, it is usually only necessary to remove the exhaust system baffle(s), the exhaust pipe(s), and the cylinder head(s). After an extended period, however, removal of the cylinder itself may be required to check or replace the piston rings. These may also become carbon-fouled.

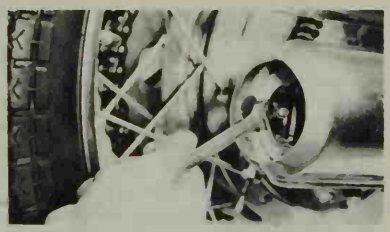
The following items are needed for this procedure:

a. A blunted screwdriver, or broken hacksaw blade, or other unsharpened device for scraping off carbon.

b. A propane torch;

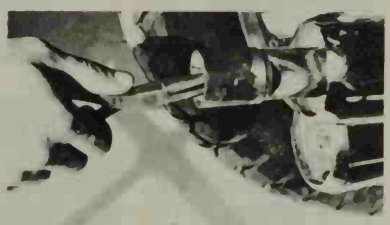
c. Some steel wool and a wire brush;

d. A quantity of solvent;



e. A torque wrench to refit the cylinder head;

f. Replacement parts: Exhaust pipe gasket(s), cylinder head gasket(s), and cylinder base gasket(s) if the cylinder is to be removed. If the cylinder is going to come off, it is recommended that the rings be replaced in any event. Piston rings not only wear rapidly on some machines, they often tend to become carbon-clogged after extended mileage. Rings in this condition are usually impossible to free without breaking them, and replacement is the only solution. The relatively small expense involved in fitting new rings makes this operation worthwhile from a maintenance standpoint.

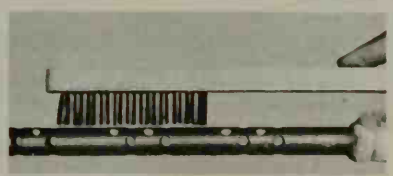


1. Remove the set screw or bolt which secures the baffle at the rear of the exhaust pipe(s). Grasp the baffle with a large pliers and pull it out.

2. Unbolt the exhaust pipe(s) from the cylinder and from the frame and remove it from the machine.

3. Loosen each cylinder head nut or bolt ¼ turn at a time, and in a cross pattern, until they are loose, then remove them and the cylinder head. If the head is stuck, tap it with a plastic mallet to free it. Remove the head gasket.

Removing the baffle securing bolt



Pulling out the baffle

4. To clean exhaust pipe baffles, first heat them with a propane torch until quite hot. Grasping the baffle with a pliers, tap it against a wooden block to knock off heavy carbon deposits. After it cools, remove any remaining deposits with a wire brush and solvent.

5. Check the amount of carbon buildup on the inside of the exhaust pipe. If substantial, much of it can be removed on some types of exhaust systems by running an old length of drive chain back and forth inside the pipe. Alternatively, a bent up coat hanger should remove most deposits at the engine end of the pipe.

Heating the exhaust pipe and then tapping the outside with a plastic mallet can remove some otherwise inaccessible carbon deposits

Remove deposits with a wire brush

Scraping exhaust pipe carbon deposits

Carbon can sometimes be removed from exhaust systems which are not chromed by heating the pipe itself with a torch and tapping the outside with care with a plastic mallet to break carbon loose.

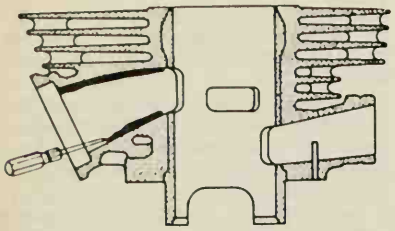
If exhaust pipe deposits are heavy, and especially if they show a wet, oily appearance, check the adjustments of the carburetor, oil pump, etc.

6. Remove carbon deposits from the combustion chamber using a blunt tool.

CAUTION: *Take care not to scratch the combustion chamber as this may cause localized "hot-spots" during operation.*

Remove as much carbon as possible, then finish up with steel wool and solvent. Leaving stubborn deposits in place is not recommended. Be sure to clean out any carbon chips which may have accumulated in the spark plug hole.

7. Remove carbon from the piston crown in the same manner. The piston must be placed at top dead center while this is done. Still, care must be taken to remove any particles which may become trapped between the piston and cylinder wall. Use compressed air



Decarbonizing the cylinder head

Use a piece of a broken ring to clean out the piston ring grooves

Removing exhaust port carbon buildup

to blow out such particles, or imbed grease between the piston and cylinder. When the piston is lowered in the bore, the grease will retain the particles which may then be wiped off. This procedure must be repeated several times to be effective.

8. To decarbonize the exhaust port, position the piston at the bottom of its stroke. Stuff a clean rag into the cylinder so that it covers the piston and blocks the exhaust port. Use a blunted instrument to scrape carbon from the exhaust port, being careful to prevent particles from entering the cylinder. If possible, parts can be decarbonized with a solvent specifically designed for this purpose, such as Gunk "Hydro-Seal."® Parts to be cleaned are immersed in the fluids for periods ranging from 4 to 24 hours. Be sure the solvent you choose is safe for aluminum.

9. If the cylinder is removed, check that the piston rings are free to move. If they are stuck, they must be freed or replacement is necessary. If the old rings are removed, clean out the ring grooves with a thin screwdriver, once again being careful not to gouge the metal.

10. When assembling, be sure that the cylinder head studs or bolts are clean. Use a torque wrench to tighten the nuts or bolts to the recommended tightness. Tighten the nuts or bolts in a cross pattern and in increments of a few ft. lbs.

STORAGE

Storage procedures will depend to some extent on the length of duration and the place where the machine is kept. Some or all of the following precautions should be taken:

1. Change the engine and/or transmission oil.

2. On two-strokes, drain the oil injection tank and stuff a clean, lint-free rag into the filler neck to keep out foreign matter and help prevent condensation.

3. Drain the fuel from the carburetor(s), fuel lines, and petcock.

4. If the machine is to be stored out-of-doors, fill the gas tank to the top. If it is to be stored in a closed area, drain the tank. Leave a small amount of gasoline in the tank and add a cup or more of oil. Slosh this mixture around inside the tank so the oil will coat the tank walls to prevent rust. These precautions are not necessary on machines with fiberglass or alloy tanks which need only be drained.

5. Remove the spark plug(s) and add an ounce or two of oil to each cylinder. Turn the engine over slowly several times, then add a little more oil. If possible, position the piston(s) at top dead center, and add a little more oil. Repeat this procedure every few weeks of storage. Stuff a piece of a clean, lint-free rag into the spark plug hole(s).

6. Place a piece of business card which has been coated with clean oil between the contact breaker points to retard oxidation.

7. Remove the battery from the motorcycle. Store it in a cool, dry place and trickle charge it monthly.

8. Put a coat of wax on all plated surfaces.

9. Support the machine vertically, preferably with both tires off the ground. Decrease tire pressure by a few psi.

10. Cover the machine with a breathable cover.

11. Before restoring the machine to service flush the gas tank and refill with fresh gasoline. Change the oil. Clean the oil out of the cylinder(s) by kicking the engine over briskly several times with the plug(s) out. Continue kicking the engine over to circulate the oil thoroughly before starting the engine (especially important on ohc models). Clean the points, check tire pressure, etc.

TUNE-UP

NOTE: *Specific tune-up procedures for individual motorcycles are given in the respective sections. Common operations applicable to all or most motorcycles follow.*

What constitutes a "tune-up" will vary according to what you ride. In general, some or all of the following items should be considered:

a. A compression test;

b. Spark plug inspection, cleaning, gapping, or replacement;

c. Breaker point inspection and gapping (if applicable);

d. Ignition timing,

e. Cam chain adjustment (if applicable);

f. Valve adjustment for four-strokes;

g. Carburetor synchronization, idle speed and mixture adjustments;

h. Carburetor cable adjustments and oil pump adjustments for injected two-strokes;

i. A road test to determine whether settings are correct or should be rechecked.

Some of these procedures are not necessary on certain models. Obviously, you do not have to worry about breaker points on CDI-equipped machines. On most magneto-ignition bikes, changing the point gap is the way ignition timing changes are made, so this will be one procedure, rather than two separate operations.

In other cases, the operation may require special equipment which you do not have, or be extremely complex. Setting valve clearances on a Triumph is easy. Hondas use somewhat smaller clearances, and are therefore a bit more difficult to do with great accuracy. Motorcycles with camshafts which ride directly on the valves have clearances adjusted with shims, and this can be a painstaking operation, and far from the ability of the average owner.

In general, however, you might need some or all of the following equipment for a complete tune-up:

A wire brush for removing spark plug deposits;

A points' file;

Wire-type feeler gauges for gapping spark plugs;

A good set of blade-type feeler gauges for gapping breaker points and checking valve clearances;

A micrometer for adjusting valve clearances on dohc engines where the cams ride directly on the valves;

A timing light or ohmmeter for checking ignition timing;

Vacuum gauges for synchronizing carburetors;

A dial gauge for determining piston position of some two-strokes;

A torque wrench for cylinder head installation if decarbonization is necessary prior to the tune-up;

A compression gauge;

A selection of small screwdrivers and wrenches.

In many cases, poor running or hard starting are due to the fact that routine adjustments which should be checked periodically have not been carried out.

If a competent tune-up is performed, and the machine still fails to run correctly, then you can begin to check more serious items.

Tune-up related items, though, are very common sources of trouble. Replacement items such as spark plugs and breaker points are subject to harsh conditions. Points will become worn just in normal use due to the job they perform. They must make and break electrical connections for spark to occur. They also have a fiber heel which is constantly in contact with the breaker cam, and this will wear.

The points will become unserviceable even faster if they are not properly adjusted, or if the condenser is bad.

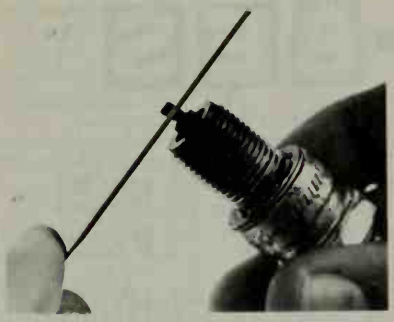
Spark plugs can last 15000 miles in some motorcycles under some conditions. They can also become fouled after only 1500 miles in other bikes under other conditions. The number of factors which affect spark plug life are legion. If the fuel/air mixture is too lean or too rich, the plugs may burn or foul. Two-stroke oil pump adjustments will naturally come into play here. If the plug is too hot or too cold for the type of riding you do, this will also have an adverse affect not only on performance, but also on the life span of the plugs.

If you have a two-stroke, even the brand of injection oil you use will have a bearing on the matter.

All these items should be kept in mind when attempting a tune-up. Manufacturers give recommended change intervals for things like points and plugs, but these are really only estimates based on their experience with machines used under "normal" conditions. "Normal" for you, certainly, may be another matter.

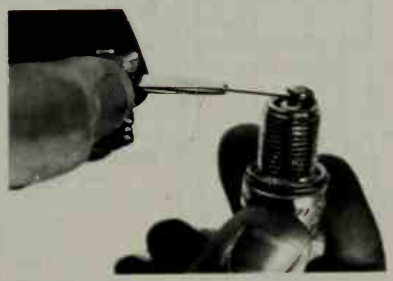
COMPRESSION TEST

1. A compression check should be made before each tune-up, as this will give a general clue to engine condition.
2. The engine should be at operating temperature.
3. Insert the gauge into the spark plug hole. If the gauge is the "hold-in" type, use a quantity of oil on the rubber tip to give a good seal.
4. Hold the throttle wide open and kick the engine over briskly. Note the compression reading.
5. Although not all manufacturers provide compression specifications, most four-strokes will average about 160 psi, and most two-strokes about 110 psi.
6. On multi-cylinder machines, the difference between cylinders is important. Cylinders must have compression within 10% of each other. If they vary more than this, suspect some sort of mechanical damage to the low cylinder(s).
7. On four-strokes with low compression, squirt a small quantity of motor oil into the cylinder and check compression again. If it is now higher than the original reading, the piston rings or cylinder are worn. If the second compression reading is not higher than the first, suspect worn, damaged, or improperly adjusted valves.
8. On two-strokes especially, if the compression increases over a series of several tune-ups, the piston crown and combustion chamber are becoming carboned up and should be decarbonized.



Checking compression

SPARK PLUGS



1. Spark plug deposits may be cleaned with a wire brush. Remove deposits from the center and side electrodes. Clean out any trapped particles with solvent or air pressure. If a commercial "plug cleaner" (sandblaster) is used, note that oily or oilfouled plugs should not be cleaned with these devices as the oil will catch and hold the abrasive cleaning particles.
2. Check electrode condition. Replace the plugs if they are worn, rounded or partially melted. "Square off" electrodes with a thin file.

NOTE: *Do not attempt to file plugs with a fine wire center electrode. This will only bend or damage the electrode making the plug useless.*

3. Adjust the gap by bending the side electrode. Plugs should be gapped with a wire-type feeler gauge, rather than the blade type, since they are more accurate.

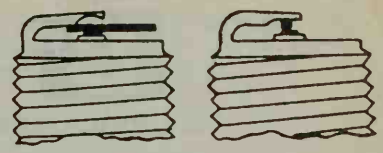
Squaring off the center electrode

Checking spark plug gap

4. If new plugs are being fitted, be sure they are the correct heat range and reach. The latter is especially important. If plug reach is too long, the lower threads will protrude into the combustion chamber. Even if the piston does not hit the plug when the engine is turned over, these threads will become carbon coated during operation, and it will become impossible to remove the plug.

If a plug with too short a reach is fitted, the plug hole will shield the spark with adverse effects on the combustion process. Additionally, the lower plug hole threads will become carbon covered, making it difficult or impossible to fit the correct reach plug later.

5. Spark plug heat range refers to the plug's ability to dissipate heat, and is dependent upon the amount of insulation around the center electrode.

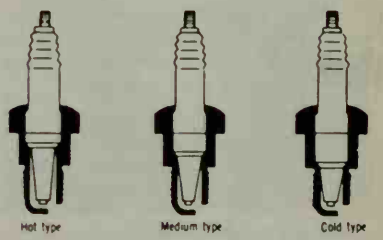


Spark plugs of a certain heat range are recommended by the various factories after extensive testing, and should therefore be suitable for most riders.

There is, however, some range of choice if performance of the standard plugs is not satisfactory. If the machine is run constantly at high speeds or under heavy loads, a plug one heat range colder than standard may be used. Note that the colder plug may tend to load up during low speed operation, however.

If the machine is run at predominately slow speeds and low loads, a plug one heat range hotter than standard can be used.

CAUTION: *Fittings of plugs more than one heat range step in either direction from the recommended plug is not recommended.*



6. Before fitting spark plugs, check that the sealing gasket is in good condition. Lightly lubricate the threads with oil or light grease. Use a torque wrench, where possible, to install the plugs. Take care not to overtighten the plugs. Plugs with 14 mm diameter threads should be torqued to about 18 ft lbs. Smaller plugs (10–12 mm) should

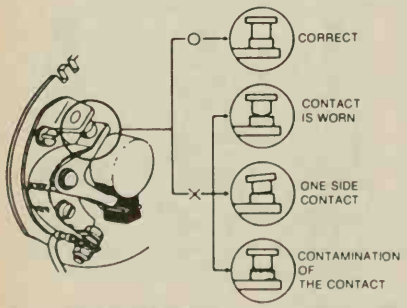
be tightened to about 12 ft lbs. If it is not possible to use a torque wrench, turning the plugs about ¼ to ½ turn after they are hand-tight should secure them sufficiently.

NOTE: *Plugs for individual models as recommended by the manufacturer are given in the "Tune-Up Specifications" chart of each section. Comparable plugs of different makes may also be used provided heat range and reach are the same.*



BREAKER POINTS

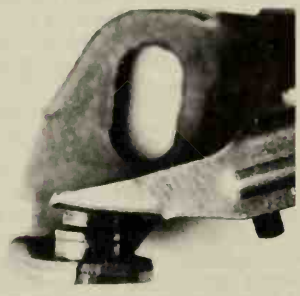
The breaker points and the condensers wired to them are one of the most critical parts of the ignition system. The points are subjected to wear through electrical arcing and wear of the heel or rubbing block which bears against the breaker cam. For this reason, the points are worthy of close attention.

Inspection

1. Make visual inspection of the breaker point surfaces. A slight graying of the surfaces is normal.

2. Check for pitting or burned spots on the points.

Breaker point conditions



3. If the surfaces are the normal gray, or if burnt spots are small, the point surfaces may be restored by running a thin, flat points file through them. This file should be designed specifically for contact breaker points, and the points should be open when using the file.

4. A too vigorous use of the file may render the points unusable. Do not remove any more material than is necessary to eliminate pitting or other irregularities.

5. After filing, clean off the points with a solvent. Finish up by allowing the points to close on a piece of business card, and then pulling it out. Continue doing this until the points no longer leave a mark on the card.

Points should be aligned when closed as shown

Points incorrectly aligned

Unserviceable points. Note deeply pitted area, cracked contact, and the fact that the pitted area is off center indicating misalignment

Check contact surface for pitting as shown

6. It is also possible to restore points by working them on an oilstone, which of course will require their removal from the machine. In this case care must be taken to avoid removing too much metal.

7. If pitting or burning is severe, the points should be replaced rather than filed.

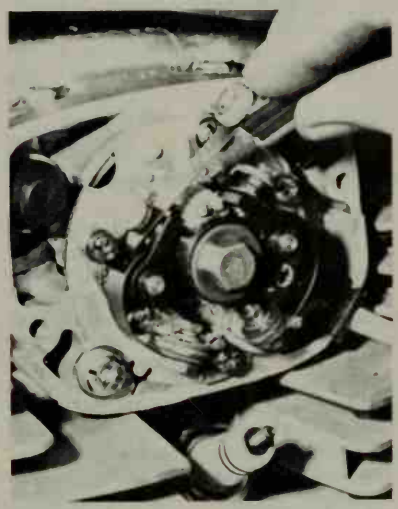
Extremely dirty points must be cleaned. Excess breaker cam lubricant is often the cause

These points show normal wear and require only cleaning to stay in use

NOTE: *New points may have a preservative coating on them to retard oxidation. This must be removed with a solvent before the points are installed.*

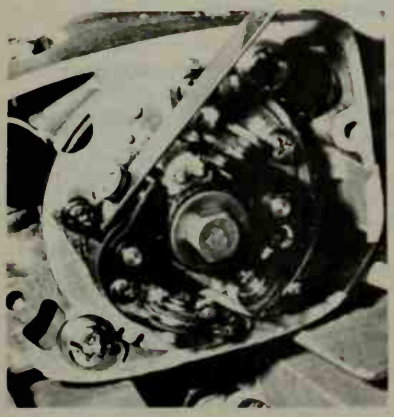
The condenser(s) should be replaced as well.

8. When closed, points should lie flat against one another. If they do not, it is possible that one of them is unevenly worn or that one or the other is bent out of alignment. In this case, replace the points.



9. On battery-ignition motorcycles, an ohmmeter can be used to give a further clue to point condition. When closed, the resistance across the points should be zero. If resistance is somewhat higher than this value, the points should be replaced.

10. If the ignition timing is being set by a static method, note that the reaction of the test light or meter should be immediate when the points open. A noticeable hesitation in the meter or light is often due to worn or dirty points.



11. Check the condition of the heel which bears on the breaker cam (if it is visible). Replace the points if the heel is excessively worn.

12. Make sure that point wire(s) are properly arranged. The moving point must be electrically insulated from the engine which is accomplished in most cases by means of insulating washers. These must be properly installed. Check the positions of any such insulators whenever points are replaced. Be sure that the points primary wire is correctly routed through any rubber grommets, and that the wire has no frayed or cut insulation. Be sure that fitting the points cover (where applicable) will not pinch the wire(s) or touch the points themselves. On some machines, clearance between such covers and the points is very small, and it may be possible that the cover will touch the primary wire terminal if installation is not correct. This will ground out the points resulting in a no-spark condition.

NOTE: *Points must be regapped after filing.*

Checking point gap

Filing breaker points

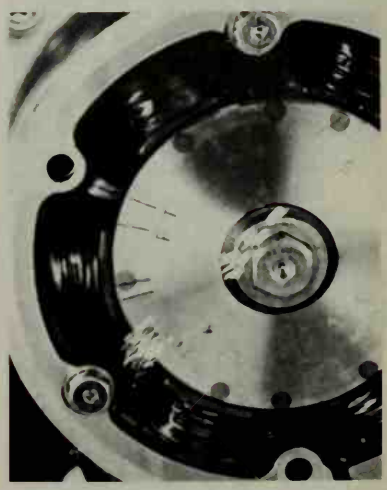
Lubrication

1. It is necessary to lubricate the point breaker cam occasionally to minimize wear to the breaker point heel, which will eventually cause retarded ignition timing.

2. Most motorcycles have one or two felt wicks so mounted that they gradually apply lubricant to the cam. A small amount of high melting-point grease should be applied to the felt, and the felt arranged to that it bears lightly on the breaker cam.

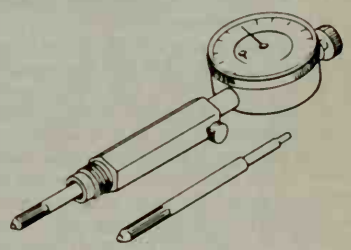
3. On a few motorcycles, the felt does not contact the breaker cam directly, but sits in the breaker cam shaft. Lubricators of this type should get a few drops of oil.

4. If the felt wick is missing, a small quantity of grease should be applied to the cam itself. Care must be taken in either case, however, not to overlubricate, or the points may be fouled.



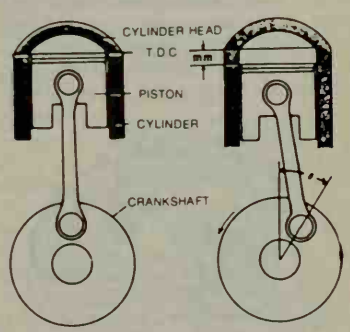
5. A drop of oil, or other lubricant such as molybdenum disulphide, can also be applied to the moving point pivot.

IGNITION TIMING



1. The ignition timing procedure varies according to the type of ignition system fitted (battery-and-coil, magneto, CDI) and according to the number of cylinders, and other factors.

2. In the most basic sense, however, ignition timing is the procedure whereby the spark plug is set to fire at an exact piston position.



3. There are two ways the plug is signaled to fire: by mechanical or electronic means. The "electronic" method refers to Capacitor Discharge Ignition systems. The more com-

Typical timing marks: "T" for top dead center, "F" for the fixed advance firing point, and two slash marks for the full advance firing point

Dial indicator for finding piston position when there are no marks provided

Ignition timing is expressed either in millimeters before top dead center (TDC), or degrees of crankshaft rotation before TDC

mon mechanical signal device refers to the familiar contact breaker points found on most motorcycles.

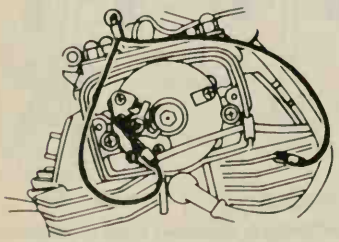
The spark plug fires at the instant the breaker points begin to separate.

4. To check the ignition timing, then, one must know when the points open, and where the piston is at this point.

Piston position can be determined in a number of ways, depending on model. On many motorcycles, timing reference marks are provided on the alternator or magneto rotor. These usually indicate piston Top Dead Center, the plug firing point at fixed advance, and the firing point at full advance.

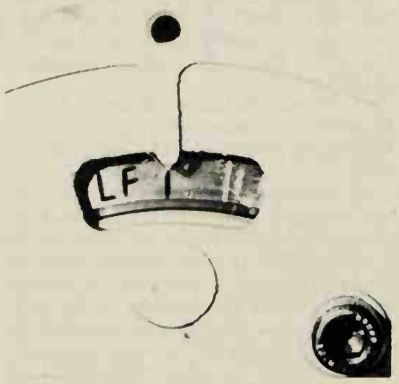
On other models, however, piston position must be determined by means of a dial gauge or a degree wheel. Since in these cases the ignition timing specification is given in millimeters or inches before top dead center, or in degrees of crankshaft revolution before top dead center, the dial gauge or degree wheel is used to position the piston at the proper spot and to check if the points open at that point.

5. When piston position has been established by one of the above methods, the next step is to determine when the points open. This can be accomplished in several ways.



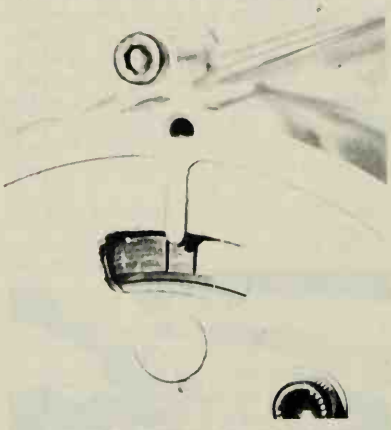
On magneto-ignition motorcycles, an ohmmeter or "points checker" is the simplest method of determining when the points open. One lead of the test instrument is connected to ground on the engine, and the other to the points primary wire, or primary wire terminal.

When the points begin to open, the meter will register an increase in resistance.



A device known as a "buzz-box" accomplished the same thing, but allows the mechanic to hear when the points open, since it changes the pitch of its signal when this happens.

Battery ignition motorcycles can be timed with a simple test or continuity light.



6. On the large majority of four-strokes, and on most two-strokes which are equipped with an electric starter, a timing advance mechanism is incorporated into the breaker cam. As the name implies, this device automatically advances the ignition timing (allowing the spark plug to fire sooner relative to the piston position) as the engine revolutions increase. This is the reason for the two sets of firing marks found on some alternator and magneto rotors mentioned previously. If an ohmmeter, test light, or continuity light is used to check the timing, the engine will not be running and you will be checking the timing at the fixed advance point unless you open the advance mechanism manually. This is "static timing." On some motorcycles, "dynamic timing" is also possible. This is done with the engine running, and it is possible to check the timing both at the fixed advance *and* the fully advanced points. To do this, an automotive-type strobe light is used. Checking the timing at the full advanced position is preferred, since this is more critical to proper engine operation.

Full advance firing point is indicated by two lines

7. On most models, the ignition timing is changed by rotating the plate on which the points are mounted, or by moving the points themselves. This allows them to open sooner or later relative to the piston movement. On others, notably two-strokes, ignition timing can only be changed by changing the point gap.

8. Breaker points should be inspected, filed and cleaned if necessary, and gapped before checking the ignition timing.

Timing Troubleshooting

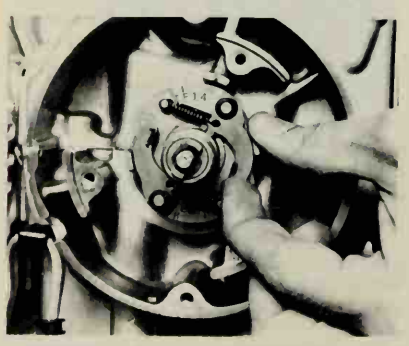
If trouble is encountered during the ignition timing procedure, check the following possibilities:

1. If the points have been replaced, check that the contact surfaces are cleaned. Some points are coated with a preservative to prevent oxidation which must be removed with solvent when the points are put into service.

2. If new points have been installed, check that all insulating washers, grommets, etc., are correctly installed. On battery-ignition systems the moving points must be electrically insulated from the engine (ground) when the points are open. On magneto ignition motorcycles there will be some continuity here in any case.

3. If there is a no-spark condition after the points have been gapped, the feeler gauge blade probably deposited some foreign matter on the contact surfaces. Clean them and try again. Such a condition may also cause sparking at the points when the engine is running, but this may also be caused by a bad condenser.

4. If it is not possible to set the gap wide enough, the breaker points heel is worn.



5. If it is not possible to set the timing correctly, a severely worn breaker point heel may be the cause. Alternately, a sticking or otherwise defective timing advance mechanism may be the trouble.

6. Using the dynamic method of ignition timing allows the operation of the timing advance mechanism to be checked. On many machines, the mechanism is fitted behind the breaker point mounting plate and is easily accessible after this plate is removed. On those magneto machines which use this mechanism, it is probably incorporated into the back of the flywheel.

Timing advance mechanisms consist of spring-controlled weights which are pivoted at one end. As engine speed increases, the centrifugal force exerted on the weights gradually overcomes the spring tension, and the weights swing out from their pivot point, carrying the cam along with them.

As shown in the illustration, turning the breaker cam in the advance direction will swing the weights out. When released the cam should return to its original position.

Sticking or frozen advance mechanisms must be replaced. It may be possible to free them with penetrating oil. The most common problem is loss of spring tension which occurs after extended mileage and which allows the advance to come on too soon.

Electronic Ignition

Electronic ignition systems (those not using breaker points) have been used for several years on a number of two-stroke motorcycles, and have recently been seen on some four-strokes as well.

Point-less systems are usually referred to as "CDI" (Capacitor Discharge Ignition) or, as in the case of Suzuki, "PEI," or Pointless Electronic Ignition.

In either case the principle is the same: the substitution of a solid-state electrical component system in place of the breaker points.

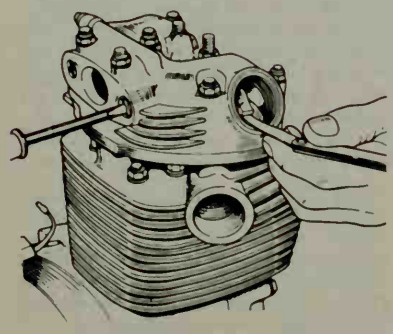
The advantages are obvious: usually, the system needs only periodic inspection of the timing which should never vary, and it obviates the need to gap, clean, or replace the breaker points. A hotter spark and more accurate ignition timing can also be obtained.

Although similar in theory, these electronic systems differ widely from make to make and it is not possible to generalize about them.

In practice, they offer either low maintenance or no maintenance once set properly, and it is usually not necessary to recheck the ignition timing as a part of the tune-up procedure. For more specific information, refer to the individual sections.

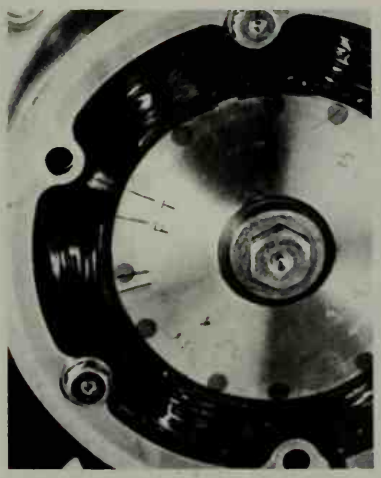
VALVE ADJUSTMENTS

For valve adjustment procedures for four-stroke engines, refer to the individual sections.



In all cases, valves must be adjusted on a cold engine.

Most motorcycles use a simple screw fitting on the end of the rocker arm to make this adjustment, although there are exceptions. Some machines, like the 350 Honda, have the rocker arms mounted on eccentric shafts, and these shafts are rotated to provide more or less clearance, the clearance being measured between the valve stem and the rocker arm. Some others use shims between the cam lobes and the valve stems to adjust the clearance, and in these instances you will need a micrometer and a selection of shims of the proper thicknesses.



On machines on which clearance can be adjusted with feeler gauge blades, note that the blade should be a slip fit in a correctly adjusted valve.

Checking valve clearance

Some models use eccentric shafts to adjust clearance

Position the piston at TDC on the compression stroke to adjust the valves

Great care must be taken when adjusting the valves. While some small error is permitted on the loose side (which will result in noisy valves), setting the clearances too tight will often burn the valves after few miles.

Before attempting to check or adjust the valve clearance, always check first that the valve is indeed fully closed. You should be able to feel a little play in the rocker arm if it can be reached.

For single-cylinder machines, position the piston so that it is at Top Dead Center on the *compression* stroke. This will allow all valves to be adjusted, since all will be closed. Piston position marks can be found on the alternator or generator rotor, and "T" will indicate top dead center when it is aligned with the stationary timing mark. Note, however, that this is no guarantee that the piston is on the compression stroke: it may be on the *exhaust* stroke. Therefore, check for clearance at the valves before going further. If one valve seems to be open, rotate the engine 360° until the "T" mark is again aligned with the timing mark and recheck for play.

For twins, the procedure is essentially the same. If rotor marks are there, they will probably be differentiated "T" and "LT", the first being TDC for the right cylinder, the second for the left cylinder.

If the twin has a 360° crankshaft (meaning that the pistons rise and fall together), there may be only one set of marks. What can be done in this case is to turn the engine over until the right (or left) intake or exhaust valve is opened by the rocker arm, then you can be sure that the corresponding valve for the other cylinder is closed, and can be adjusted. Continue to turn the engine over in like manner until all valves have been checked.

Three- and four-cylinder engines are somewhat more complicated and information regarding them can be found in the individual model sections.

CAM CHAINS

Occasional adjustment of cam chains is necessary on most overhead-cam motorcycles in which the cam is driven by this method. Some, however, have hydraulically-tensioned chains which need no attention.

On most designs, the chain tensioner consists of a spring-loaded rod with a chain slipper at one end. When the crankshaft is positioned at the point yielding the most slack at the point on the chain where the tensioner is located, a nut or bolt is loosened which releases the rod and allows the spring tension to take up the chain slack. The locknut or bolt is then tightened securing the rod in this position.

Obviously, the most important part of the procedure is ensuring that the crankshaft is properly positioned. Usually, the position will be given with reference to the timing marks on the alternator rotor.

Refer to the individual model section for specific cam chain adjustment procedures.

CARBURETORS

Carburetor tune-up procedure will largely depend upon the type of engine, the type and number of carburetors, what kind of carburetor controls are fitted, and ancillary systems, if fitted, such as oil pumps and the like which operate in conjunction with the carbureator.

Carburetor adjustments must always be made when the engine is at operating temperature.

Pre-Adjustment Checks

Before attempting to make carburetor adjustments, all of the following points should be checked:

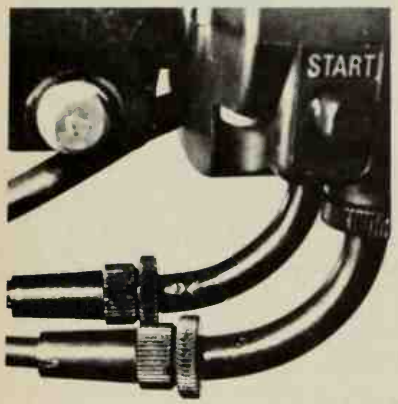
1. Carburetor alignment. On flexible-mounted units, ensure that the carburetor(s) are vertically oriented, and not tilted to one side or the other. This may effect fuel level and high-speed operation.

2. Cable condition. Check throttle operation, ensuring that the cable(s) are not kinked or binding, and that they and the twist-grip are well-lubricated. If the gas tank has been removed and reinstalled, check that it has not trapped or pinched the throttle cables, or that the cables have not been forced to make sharp bends anywhere along their route.

3. Ancillary systems. Carburetor adjust-

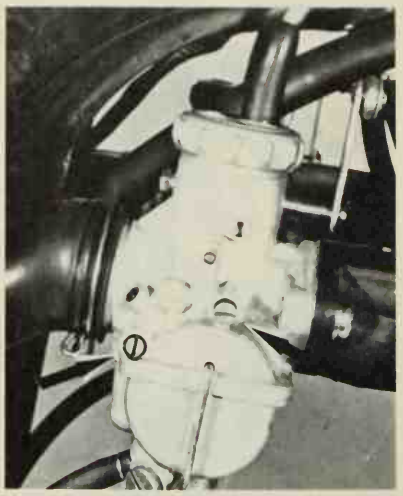
ments should be made last after all other systems have been attended to in order to prevent misleading symptoms. Check that the air clean is serviceable, the spark plugs are in good condition, valves (four-stroke) are correctly adjusted, and the ignition timing at least approximately correct. Also ensure that the gasoline is reasonably fresh, of the correct octane, and that foreign material, such as water or dirt, has been purged from the fuel system. Check fuel filters, if applicable.

Cable Adjustment



1. On most motorcycles, provision is made for adjusting the throttle cable to compensate for stretching. The adjuster is usually found at or near the twist-grip. This device should be adjusted so that the twist-grip has a small amount of noticeable free-play when turned. In general, this free-play should amount to about 10–15° of grip rotation before the slides begin to lift.

2. On oil-injection two-strokes, the oil pump cable adjustment must be checked any time the throttle cable is adjusted.



3. After adjustment, turn the forks slowly from side to side with the engine idling. Idle speed must not change or the cable is too tightly adjusted or too short. Check routing.

Idle Speed and Mixture

Idle speeds which are recommended by the manufacturer should be adhered to in most cases. The idle running of a motorcycle engine is usually the most unsatisfactory carburetor range. There are many reasons for this. For one, the quantities of fuel and air which are going into the engine are relatively

Throttle cable adjusters

Direct-control carburetor. Pilot air screw (left) and throttle stop screw (center)

small, and are controlled by equally smallish passages. These are more likely to become clogged with dirt or varnish than the much larger jets, and the mixture will then be upset. Further, the relative quantities of gas and air are more critical at idle, a situation which is compounded by the fact that one or the other can be adjusted by means of a knob or screw on the outside of the carburetor, and can easily be adjusted incorrectly.

Finally, since the engine is turning slowly, and is not under load, any irregularities in the mixture flow cause an erratic idle which may be irritating.

On most motorcycles, a satisfactory idle can be obtained by carefully setting the carburetors, ignition, and plugs to the recommended specifications. As noted, above, idle speed should be set to the recommended specification. An idle speed which is too low may cause trouble by making smooth transition to the slow or mid-range circuit impossible. On some motorcycles, too low an idle may cause damage to bearings and other moving parts due to the great lapse between power pulses.

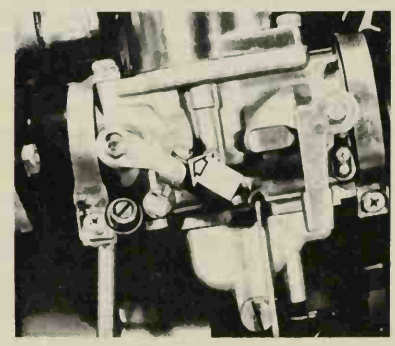
On the other hand, too high an idle speed may cause the rpm to hang up for a moment or so when the throttle is closed. It may also make engaging the gears noisy or difficult, or result in excessive brake lining wear by negating the effects of engine braking.

Because of the low engine speeds involved, minor misadjustments or slightly defective components will be much more noticeable at idle.

The idle mixture is determined largely by the *pilot air screw* which controls the amount of air mixing with the idle circuit jets, or the *pilot fuel screw* which controls the amount of gasoline passing into the circuit.

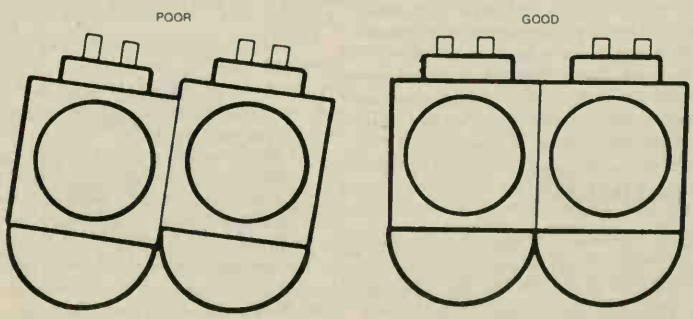
Carburetors may be equipped with one or the other of these screws. While exceptions exist, on most carburetors the location of the screw will indicate whether it is an air screw or a fuel screw. Generally, pilot *air* screws are located on the intake side of the carburetor, while most pilot fuel screws are located between the throttle slide and the engine manifold. Most "CV" carburetors use pilot fuel screws.

It is only important to know whether you have an "air screw" or a "fuel screw" if you intend to make mixture changes based on plug readings or road tests. Turning an *air* screw *in* will give a richer mixture, while turning it *out* will lean the mixture out. For pilot *fuel* screws, exactly the opposite is true.



Regardless of type, pilot screw settings are given by the manufacturer, and should be adhered to, at least to within certain limits. The pilot screw settings are expressed in *turns out from the seated position.* The pilot screw's tip is tapered and is mated to an air or fuel passage. To make the adjustment, the screw is turned in gently until you can feel that it is *lightly* seated, then backed out the given number of turns. For example, if your specification for the pilot screw setting is "2½," you will back the screw out this number of times.

When turning these screws in, it is best to be very careful, as it is possible to ruin the tapered portion of the screw if it is turned down too tightly.

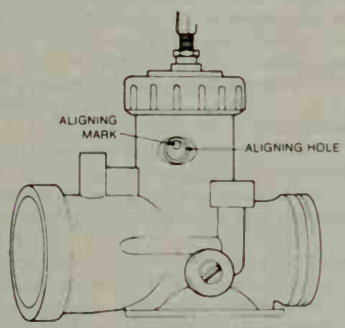


When performing a tune-up, always turn the pilot screws out to the given specification, then make any necessary adjustments. It should not be necessary to vary the screw setting more than ½ turn from the given setting unless changes have been made to the intake, engine, or exhaust systems. If it is not possible to obtain satisfactory performance with the settings as specified, suspect clogged carburetor passages or air leaks, etc.

NOTE: *On many late-model motorcycles, the pilot screws are covered with limiter caps or other devices which will prevent any readjustment. These caps are fitted to conform with clean air regulations, and they should not be removed, nor should the pilot screw setting be changed.*

Due to the large number of differing throttle linkage and carburetor assemblies used

CV carburetor. The throttle lever screw (arrow) adjusts idle speed while the pilot fuel screw (near manifold clamp) controls idle mixture



If flexibly-mounted carburetors are fitted, be sure they are vertically aligned

Throttle stop screw

today, no general procedure will be able to provide all of the information necessary to properly adjust the carburetors on most motorcycles.

A few of the easier procedures are given below, but on most multi-cylinder machines, idle speed and mixture are controlled by complex linkages and are accomplished in many cases in conjunction with throttle slide synchronization, a procedure which requires a vacuum gauge. Therefore, detailed procedures for tuning these machines can be found in the applicable model section.

Some carburetors have slide alignment marks to facilitate synchronization

SINGLES

1. Single-cylinder machines, whether two- or four-stroke are easily adjusted in the following manner.

2. After setting the pilot screw to the given specification, allow the engine to warm up, then use the throttle-stop (or idle speed) screw so that the engine turns over at the specified rpm.

3. Smooth out the idle, if necessary, by making careful adjustments to the pilot screw, but do not turn the pilot screw more than ½ turn in either direction from the recommended specification.

4. If satisfactory performance cannot be obtained using the given specifications, check for clogged carburetor passages, air leaks, plug condition and gap, timing, damaged components, etc.

TWINS

For single-carburetor models, refer to "Singles," above. For dual carburetor machines, the procedure is as follows:

1. Adjust the pilot screws for both carburetors to the recommended specification.

2. To ensure that one cylinder is not "leading" the other it is necessary to equalize the idle speed.

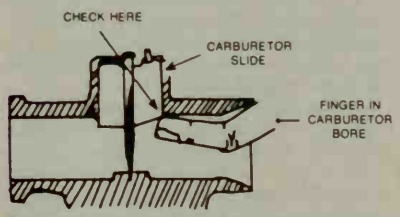
3. With the engine at operating temperature, disconnect one plug lead and turn the idle speed screw on the running cylinder in until the engine will run on one cylinder. Adjust the running cylinder's idle so that it is as low as possible, then try to get it as smooth as is feasible using the pilot screw.

Do not turn the pilot screw more than ½ turn in either direction from the recommended setting.

4. Connect the disconnected plug lead. Rev the engine a few times to clean off the spark plugs, then disconnect the plug lead for the cylinder which has already been adjusted.

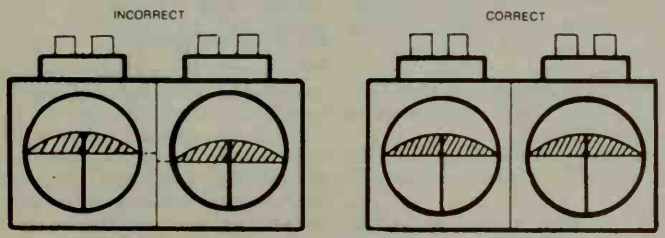
5. Repeat Step 3 for the other cylinder.

6. Connect both leads. Idle speed will be very high. Back out each carburetor's idle speed screw in small, equal increments until the desired idle speed is arrived at.



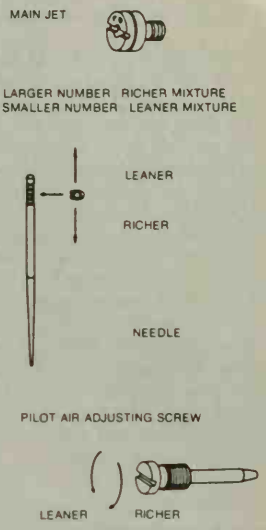
NOTE: *On twins using a single ignition coil, disconnecting one lead will kill both cylinders. To get the engine to run on one cylinder it will be necessary to allow the disconnected lead to ground its spark against the cylinder head.*

7. Synchronize the throttle plates (CV) or slides.



On CV carburetors this can be done by opening the throttle slightly and checking that both throttle arms begin to move at the same time.

On direct-control carburetors, remove the air cleaner(s) and check that both slides begin to move at the same time.



On some late-model twins, the throttle slides are fitted with a punch mark which can be aligned with inspection holes on the carburetor bodies for synchronization.

Check for carburetor synchronization by ensuring that both slides clear the carburetor bores at the same time

On multi-cylinder machines, throttle slides must be synchronized

Carburetor metering components. If the unit has a pilot fuel screw, reverse the direction of those arrows to lean or enrichen the idle mixture

An alternate method is possible on some machines. Turn the throttles open until one of the slides just clears the carburetor bore. Check by feeling the top edge of the bore with your finger. The other slide must be in exactly the same position.

Slide synchronization is adjusted on most units by means of he the cable adjusted atop each carburetor, or at the side on CV units.

Carburetors can also be synchronized with vacuum gauges if appropriate fittings are there.

TRIPLES AND FOURS

Late-model triples and fours utilize throttle pulleys and linkages and you should refer to the specific section for precise adjustment procedures. For others with separate cables to each carburetor, the procedures are very similar to that described above for twins. Many models have punch marks on the throttle slides which are to be aligned with inspection holes on the carb bodies to effect synchronization.

Road Test

NOTE: *Before carrying out any of the following tests, new spark plugs of the factory-recommended heat range should be fitted. Before making any alterations to the carburetor jetting based on the tests below, be sure that the carburetor does not have any air leaks, or that the engine is not carbon-choked, or running with worn rings, bad valves or seals, etc. Deceptive readings will be obtained in these cases, and if the unbalanced mixture is being caused by mechanical malfunction such as a leaking carburetor float needle, wrong float level, punctured float, blocked or obstructed fuel lines or gas tank vent.*

The following test is for the main jet.

1. Warm up the engine and accelerate through at least the first three gears at full throttle. When the engine is pulling high rpm, shut off the throttle, pull in the clutch,

and kill the ignition, all as simultaneously as possible.

2. Remove the plugs and note the color. The plugs should be light tan to dark brown in color if the carburetor settings are correct.

3. If the plugs are black and wet with gas or oil, the mixture is too rich, and smaller size main jets should be installed. If the plugs are white, the mixture is too lean and larger main jets should be fitted. Main jets are sized accordingly: the larger the number on the jet, the more fuel it will pass in a given time, and the richer the mixture will be.

NOTE: *Never change main jet sizes more than one increment at a time; each time new jets are fitted, repeat the test until the plugs show the proper color. All plugs must show the same reading. The use of caution is advised when fitting smaller main jets. Too lean a mixture will cause overheating and probable piston seizure.*

4. Once main jet size is determined to be correct, mid-range operation should be checked. Mid-range mixture is controlled by the needle jet and the needle. Repeat the test above, but do not use more than half-throttle when testing. Adjust the mixture by moving the needle clip up or down.

NOTE: *After considerable mileage, the needle and needle jet will become worn. This will cause a rich mid-range condition. If this occurs, replace both the jet and the needle.*

5. Mixture at idle and just above idle is controlled by the pilot screw. This adjustment is covered above.

CAUTION: *The effect that other badly adjusted or worn engine components can have on spark plug color cannot be overemphasized. Since main jets and other carburetor settings are determined by the factory after extensive testing, it is wise to suspect that things other than the jet sizes are causing misleading plug readings.*

Throttle Opening	Mixture too Rich	Mixture too Lean
0–1/8	Turn pilot air screw out, pilot fuel screw in	Turn pilot air screw in, pilot fuel screw out
1/8–1/4	Enlarge throttle slide cutout	Reduce throttle slide cutout
1/4–3/4	Lower the jet needle	Raise the jet needle
3/4–full	Use smaller no. main jet	Use larger no. main jet

ENGINE REBUILDING

The following section is provided to give the novice some idea of the methods and techniques used in rebuilding an engine and/or servicing various engine components, as well as indicating to a certain degree the kinds of tools necessary for this kind of work.

The model sections, of course, provide step-by-step procedures for specific motorcycles as well as giving all necessary specifications.

IS REBUILDING NECESSARY?

Before beginning any procedure like engine rebuilding which will necessarily entail a good deal of time and money, it is worthwhile to determine first whether rebuilding is indeed necessary. Of course, if there is a major component failure (such as a sudden and total loss of compression) the answer is obvious. In most cases, however, rebuilding is undertaken to cure less obvious malfunctions, or to repair damage due to normal wear which takes place over a long period of time and many miles.

Even in the event of seemingly serious engine or transmission trouble, it is important to do a bit of preoperative testing or diagnosis prior to simply tearing the engine down. For example, if the transmission jumps out of gear, the cause may be due to worn or damaged engaging dogs on the gears themselves—and this will require splitting the crankcases: a major undertaking. On the other hand, this sort of problem may also be caused by a defect in the shift linkage. It then becomes a relatively simple job which in many cases can be fixed with the engine in the frame.

Another example is poor engine performance. While this can be caused by worn out rings or cylinders, it is equally likely to be due to dirty or out-of-adjustment components in the tune-up system: points, air filters, carburetors, etc. Obviously, these simple parts should be checked before jumping to conclusions.

If you think you need an engine rebuild, it may save a great deal of time and money to first refer to the "Troubleshooting" diagnostic charts in this manual. Also, examine the motorcycle itself closely and take into consideration its past life: mileage, maintenance history, etc.

Some of the most obvious needs for an engine rebuild are given below.

Mechanical Noise

Few engines stop suddenly without providing some sort of warning in the form of unusual mechanical noise. Of course, some do. Piston seizure is one example, although if this happens you will know right away what the problem is.

Noises can usually be isolated, and to some extent analyzed, by determining when they occur and from what part of the engine they come.

Top end noise is perhaps the most common. This can arise from badly adjusted valves, but you must determine whether the valve noise is a result of the need for periodic readjustment or something more serious such as indented valve stems, worn or damaged adjusters, worn cam lobes, scored or worn camshaft bearings, bent valves or damaged valves or seats.

If the noise is confined to one valve (and you can usually tell, since the ticking will be unmistakable) some sort of mechanical damage is likely. In any event, check the clearance and proceed from there.

Another common top end noise is due to a loose or worn cam chain. Readjust the chain according to the given procedures. If the noise persists the chain may have to be replaced. This type of problem is almost always confined to very high mileage motorcycles, or those on which the chain was improperly adjusted. You can check this on some machines on which the cam chain also drives the breaker points. If the ignition timing marks seem to jump all over the place when strobe-timing, chances are that a worn cam chain is the cause.

A grinding or whinning noise from the top end of ohc engines may be due to worn or scored camshaft bearings.

Lower end noises are a bit harder to identify, since there are many more potential causes.

A clicking or 'snapping' noise, especially noticed when the engine is cold or just when the clutch is let out and the engine put under load, may be due to piston slap-worn pistons and/or cylinders.

Roller bearing lower ends can sometimes give indications that they are damaged by a rumbling sound which increases in pitch as the engine speed increases. Under heavy load, a badly damaged ball or roller bearing may produce a rapid thumping.

Plain bearing lower ends are usually a little quieter, but they, too, will whine or bang under load.

A knocking sound in the lower end, especially when the engine changes speed, may be due to worn or damaged connecting rod plain bearings. If the rod bearings are roller-type, the noises may be similar to those of a ball or roller lower end as described above.

Transmission noises are usually easier to identify. About the only really serious symptom is gear noise which indicates worn gear teeth. Chattering or grinding sounds may be due to worn or damaged transmission shaft bearings, but this is very unusual.

Performance Loss

Loss in performance is difficult to notice since it most often occurs over a long period of time, and is intrinsically tied up with tune-up adjustments and service procedures which are often ignored.

Before taking an engine apart because of loss in performance, first go over all of the tune-up operations and maintenance items relating to the ignition and fuel systems. On two-strokes, decarbonize the engine and exhaust system.

Make a compression check (see "Tune-Up," above). This is one of the most revealing tests you can carry out without dismantling the engine.

Oil Consumption

Oil consumption is one of the most common symptoms of worn engine components and one of the easiest to identify.

The only problem is determining how much oil consumption you can live with. Many people are willing to put up with an oil burner until the tell-tale blue-white smoke from the exhaust pipes becomes embarassing.

All engines will consume some oil under certain conditions. Four-strokes, however, are not supposed to smoke noticeably, and when this happens you can be sure that wear in the engine has become excessive.

Note that oil smoke is blue or blue-white. Black smoke is carbon or unburned fuel, and may be caused by excessive carbon build-up on the piston crown or combustion chamber, an excessively rich fuel/air mixture, incorrect ignition timing, or other causes.

Oil burning may be due to worn rings, worn pistons or cylinder bores, worn valves or valve guides, damaged valve seals, or broken rings.

Wet, black, oily spark plugs will confirm oil burning. If all of the plugs of a multi-cylinder high-mileage machine are in this condition, normal, long-term wear is the cause. If only one plug is oil-fouled, suspect mechanical damage to that cylinder.

ENGINE REBUILDING METHODS

General Service

1. Engine work requires extra care and attention to detail especially during disassembly and assembly procedures. While largely a matter of common sense, the following points should be noted.

2. It is important that no undue force be used when removing or installing engine parts. If a part resists removal, be sure you are using the correct procedure and the right tool. Use a parts loosener or penetrating oil whenever necessary.

3. Phillips-head engine screws should always be removed and installed with an impact driver. Not only are these screws put on tightly to begin with, on some models they tend to seize in the cases due to corrosion on the threads.

4. When threading and screw or bolt into an allow casting (such as crankcases or cylinder heads), it is recommended that the threads be coated with an antiseize paste. Alternately, oil or grease can be used, but these may not work as well as the paste. The reason for this is to prevent the screw or bolt from seizing in the alloy casting which makes future removal easier and minimizes the chance of damaging the threads or snapping the screw or bolt while attempting removal.

5. A torque wrench is a necessity for most engine work, especially if the cylinder head is removed. Because of the high temperatures at which cylinder heads run, and the resultant expansion, an improperly torqued head may allow compression leaks, blown head gaskets, and/or a warpage of the head itself. It should be noted that a compression leak will very often cause the engine to seize in a short time.

6. When tightening a bolt or nut for which a torque specification is given, be sure that the threads are clean. Oil them lightly where possible to ensure an accurate torque reading.

7. When securing a component which is held by two or more bolts or nuts or screws, tighten them gradually and in a cross pattern so that the component goes on straight. Cylinder head bolt or nut tightening orders are given in the individual sections, and for some motorcycles, crankcase bolt tightening orders are given as well.

8. In most cases, gaskets should be replaced rather than reused. This is especially true of metal gaskets which derive part of their sealing ability from being compressed when the part is torqued. Once disturbed, the gasket may not provide the same seal as when new.

Sometimes, however, it may be easier to leave paper gaskets alone if they are in no way damaged.

Copper sealing washers can often be renewed by heating them until they are red-hot, then allowing them to cool. This will soften the copper, allowing it to form a better seal.

9. The use of gasket compounds or sealing agents is sometimes recommended by the manufacturers, and when this is the case, it will be noted in the text of the individual sections. In other cases the uses of such compounds is optional, but they are usually not needed. On the majority of modern motorcycles, the thickness of gaskets and the width of mating surfaces make gasket compound unnecessary. Oil leaks are therefore not inherent in the design, and if the engine does leak, it is probably due to a damaged gasket, a knicked or warped mating surface, or an improperly installed part. Determine the cause before attempting to stem the leak with gasket compound.

Additionally, the use of such compounds may make future removal of the gasket a chore, since all traces of the old gasket and compound must be removed from the mating surface.

If gasket compound is used, it must be applied carefully, to avoid clogging oil passages or being squeezed into the engine when the part is tightened.

Be sure to follow manufacturer's instructions for suitability and use.

10. For some operations, special tools are required. For safety and reliability, it is suggested that you purchase these tools where possible.

11. Whenever engine components are removed, they should be marked for position whenever the potential for incorrect installation exists. This is especially true for parts like pistons, valves, valve springs, etc., which must always be installed in the same location from which they were removed.

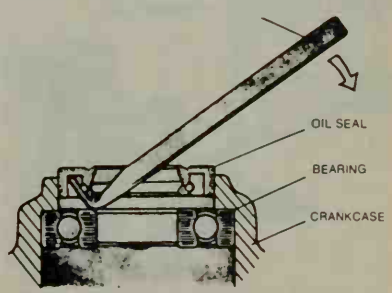
12. All engine components should be lubricated by hand before the engine is started after work has been done. For example, piston rings and skirts should have a coating of motor oil on them before the cylinder is installed. The same holds true of crankshaft and connecting rod bearings, cams, rocker arms, etc.

13. The replacement of parts which are not reusable should be considered before disassembly. Gaskets and oil seals are obvious. In many cases, however, the reuse of snap-rings and cirelips is specifically not recommended. These items are often deformed by removal and should be replaced. Of special importance in this regard are piston wrist pin and transmission shaft cirelips.

14. While most engine components can be cleaned in a safe solvent after removal, this procedure is not recommended for roller and ball bearings which are going to continue in use. Immersion in any but the purest solvent may allow minute particles to enter the bearing, causing a rough movement and possible damage. It is preferable to clean ball and roller bearings by squirting clean motor oil through them. This will serve to carry away the greater part of any particles which may have entered the bearing.

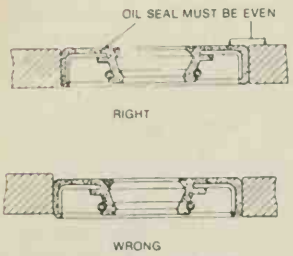
15. Some components are pressed into place, and heat or cold may be used to facilitate removal. An example is bearings or bushings which are tight fits in an alloy case. Since the expansion rate of an alloy when subjected to heat is greater than that of steel or iron, the case can be heated before removing the bushing or bearing. This can be done with a propane torch, but care must be taken to heat the alloy gently and evenly, and to keep the flame off the bearing. However, since uneven heating may cause the alloy part to warp, it is somewhat safer to heat it in an oven or on a hot plate. Extreme heat should not be necessary. Since some of the heat will be transfered to the bearing or bushing, removal can be made even easier in some cases by running a damp rag or an ice cube around the bearing. The chill will cause it to contract very slightly, and, since the heat caused the alloy to expand, the bearing or bush should come right out.

This handy aid cannot be used in other situations. For example, it is not possible to remove a ball or roller bearing from a steel shaft by heating. The expansion rate will be about the same and the swelling of the shaft will nullify any expansion of the bearing. In addition, as noted above, bearings should not be heated by contact with a flame.



There are some instances in which heat will not work. For example, when pressing a bushing into a case. Although the normal procedure would be to heat the case, sometimes the bushing may be made from a substance with like characteristics. The heat may be transferred to the bushing as soon as it contacts the case. It will then expand making installation very difficult. Such occurences are rare, but the possibility should be recognized.

16. After a four-stroke engine has been rebuilt, and all settings checked, it should be run for several miles, allowed to cool, and the head should be retorqued. Readjust valves and cam chain, if applicable.



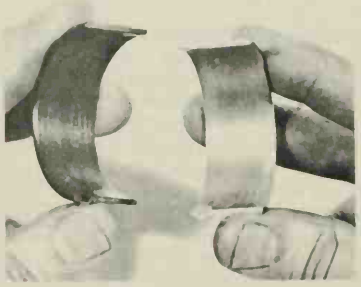
17. Follow owner's manual instructions for the care of a new engine if extensive rebuilding was done. Keep a close watch on engine temperature for the first several miles after the rebuild.

Bearings and Seals

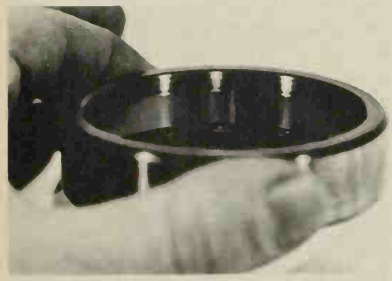
1. Many bearings (such as for the crankshaft and transmission shafts) are fitted with an oil seal. If removed, these seals must be replaced. Seals which are pressed into their housing may be pried out with a hooked tool.

Removing an oil seal

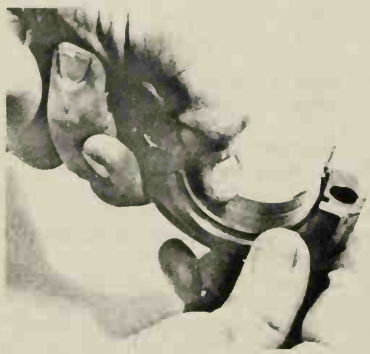
Correct and incorrect seal installation



as illustrated. When fitting a new seal, be sure it is not cocked or tilted in the housing. Lubricate the lips of all seals before inserting any shaft into them.

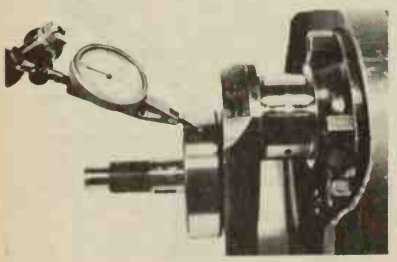


2. A rough check of the condition of ball and roller bearings can be obtained by lubricating them with oil, and noting any binding, roughness, or noise during rotation. Binding may be due to foreign particles which found their way into the bearing during the disassembly procedure, and they can sometimes be removed by squirting clean oil through the bearing. If roughness persists, or if the bearing is obviously damaged with pitted or discolored balls or rollers or scored races, it must be replaced.



3. Some bearings can also be checked by holding the outer race firmly in place, as illustrated, and attempting to move the inner race back and forth. No movement should be possible.

4. A more precise method of checking bearing clearance involves the use of a dial gauge.



5. Plain bearings must exhibit a perfectly smooth, featureless surface, or they must be replaced. Clearance of plain bearings is best checked with Plastiguage® or by measuring the bearing journal and subtracting this value from the diameter of the bearing itself.

Plain bearings should be featureless as on the right

Top End

The following procedures are common to most motorcycles.

While most of the following inspections are written in the singular, bear in mind that any work done to one cylinder must be done to all of them in a twin or multi. Some parts, such as valve springs, piston rings, pistons, etc., must of course be replaced in sets, even if only one is unserviceable. Boring, honing, valve lapping, etc., must be done to all of the cylinders for the same reason.

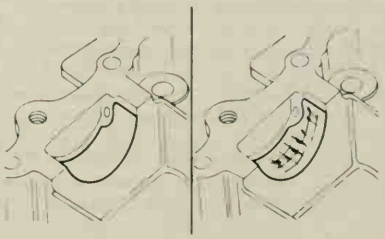
FOUR-STROKE

Cylinder Head

1. Clean carbon deposits from the cylinder head using a wire wheel or a blunt instrument such as a butter knife or the rounded edge of an old hacksaw blade. Do not use a pointed instrument.

NOTE: *Decarbonizing the head with the valves in place is recommended as this minimizes chances of damaging the valve seats.*

2. Make a check of valve seating efficiency by pouring a small quantity of gasoline into each of the ports and allowing it to stand for about five minutes. If the valves are seating properly, leakage into the combustion chamber will be minimal. If the gasoline leaks in quickly, the valves should be lapped.



Before removing the valves, note that most models and that progressively wound valve springs and that these types of springs are always installed with the close pitch side toward the head. Also, each spring should be assembled to its own valve, and each valve to its guide. Mark the pieces for location as they are removed.

3. Valves can be removed after compressing the valve springs with a spring compressor. On some machines, they can be removed with a suitably sized socket. Turning the head upside down and pressing the valve spring against the socket while holding the valve against its seat should allow the valve keepers to fall out. When they do so, the spring assembly and valve can be removed. Remove the retainer, springs, spring seats and any washers fitted. Remove the valve guide oil seals, if so equipped.

NOTE: *New valve guide oil seals should be used on assembly.*

4. Check the cylinder head for warpage, where possible, by placing it on a very flat suface such as a piece of plate glass and prob-

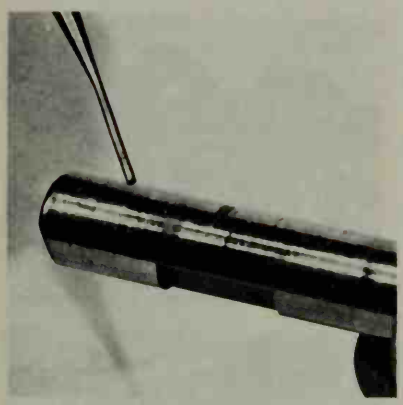
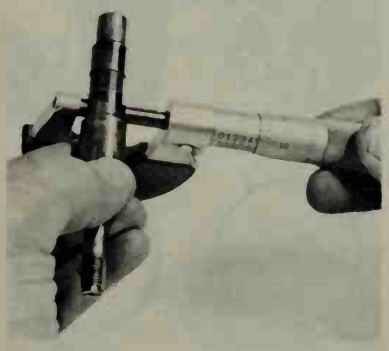
ing around the cylinder mating surface with a thin feeler gauge. The head mating surface should be very flat (i.e., it should not be possible to slip the feeler gauge between the head and the glass). If it is warped, the head can be lapped. Be sure to remove only enough metal to rectify the warpage. If warpage is slight, it can sometimes be remedied by putting a quantity of valve lapping paste on the glass and working the head back and forth in a figure-eight motion until the mating surface is flat. A sheet of emery cloth placed on a flat surface can also be used. Ensure that the head is cleaned up very thoroughly after this operation. Check oil passages especially.

5. Some overhead camshaft motorcycles have the camshaft(s) riding directly on journals cast as part of the cylinder head. Others use cam bearing housings which are removable. In either case the bearing surfaces must be smooth and featureless. Removing any imperfections from these surfaces by abrasive methods may make the cam-to-bearing clearance unacceptable.



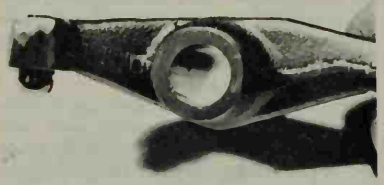
6. Where applicable, check that the rocker arm shafts are a snug fit in the cylinder head, not excessively loose.

7. Check that all head and valve cover gasket surfaces are clean and smooth. Remove all traces of old gaskets or gasket compound.



Valve Assembly

1. Check the condition of the rocker arm shafts. They should be free of obvious signs of wear, scoring, or discoloration due to overheating. Measure the diameter of the shafts at two or three places along their length.



NOTE: *If any top end components show signs of discoloration it is usually the result of overheating, and the cause must be determined. Check the lubrication system, oil passages, etc.*

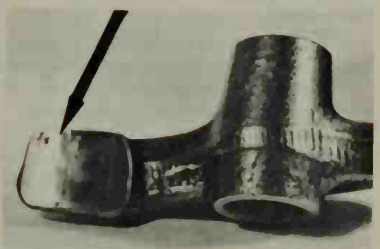
Check the shaft bore for scoring and the ball end for blueing or imperfections



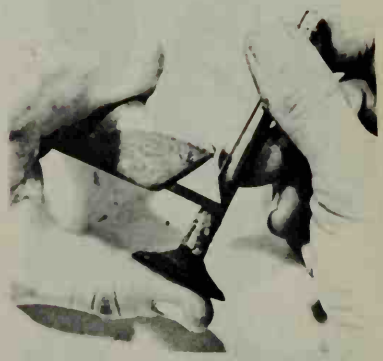
Check the shaft and rocker for vertical play

2. Check the inner bore of rocker arms for scoring. If any wear is evident, replace the rocker arm. Insert the rocker arm shaft into the rocker arm and check for play. There should be none. Or, if the proper instruments are available, measure the bore of the rocker arm and compare it to the diameter of the shaft.

Check the cam follower pad (where applicable) for pitting or wear. If any is present, replace the rocker arm. Removing score marks by grinding is not recommended.

On pushrod models, check the ball-end of the rocker arm for damage. The ball should be smooth and shiny.

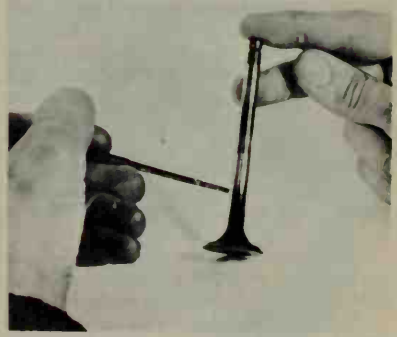
3. With a vernier caliper or a short steel rule, measure the free-length of both the inner and outer valve springs. Replace springs in sets if any of them has been compressed beyond the serviceable limit.



Pitted rocker arm pad

Measuring valve spring free length

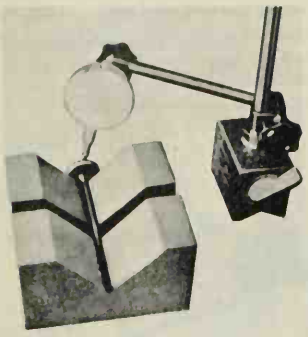
4. When the valve springs are removed, the valve should come right out of its guide. Any sticking or binding as the valve is pulled out will indicate that the valve stem or guide is in bad condition.



5. Inspect the valve paying close attention to the condition of the edges of the valve head for pitting, burnt or broken edges, excessive carbon build-up, etc. A certain amount of carbon build-up on the valve face and on the top of the exhaust valve head is inevitable. These deposits should be carefully scraped off with a dull knife, or with a wire wheel, and the valve finished with a fine emery cloth.

Decarbonizing a valve

A burnt valve. Note chipped edges



Deposits should not extend too far up along the valve stem

Do not touch the valve seating area during these operations.

Carbon deposits, however, should not extend too far up along the exhaust valve stem. This would indicate a worn or cracked valve guide.

Wet oil on the back of the valve head is indicative of a worn guide (which must be replaced) or bad seal.

Check for a bent valve

Measuring valve stem diameter

Indented valve stem

Holding the valve stem, spin the valve in your fingers and watch the head. A wobble in the rotation of the head is indicative of a bent valve. Valve head runout can also be measured with a dial gauge.

6. Check the diameter of the valve stem with a micrometer.

A quick check of the operational worthiness of valve and guide can be done by putting a small amount of engine oil on the stem and inserting the valve into the guide. Place a finger over the other end of the guide and pull out the valve. A slight "pop" should be heard.

A valve should move smoothly in the guide. If any tightness or sticking is encountered as the valve is pushed into or rotated in the guide, it is probable that the valve is bent.

A bent valve must be replaced, and if one is found, it is wise to inspect its guide very carefully, as it is likely to be cracked.

7. Check the end of the valve stem for indented wear which may be caused by some types of rocker arms. Although this damage can be remedied on some machines by grinding the end of the valve, this procedure is not recommended since many manufacturers use stellite-tipped valves. Grinding may remove the hardened stellite surface and the indentation will reoccur more quickly.

8. Valve-to-guide clearance can be measured by comparing the diameter of the valve stem with the inside diameter of the guide. Or, by placing the valve into the guide, holding it about ½ inch off its seat, and checking movement in two directions with a dial gauge.

9. Valve guides are replaced by driving them out with a drift. It is often necessary to heat the head before driving out the guides to avoid scuffing or enlarging the guide bores. Do not exceed 300° F.

If the guide is cracked, it may be necessary to chisel off the portion which extends into the port to allow removal.

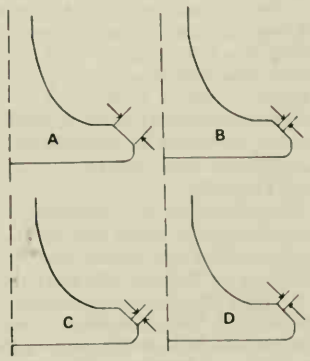
10. Most models have oversize guides

Checking valve-to-guide clearance

available. Installation is accomplished by pressing the guide in until it is fully seated.

11. After installation of a new guide, the guide must be reamed to the proper size and the valve seat must be recut.

Valve Seats



1. Valve seats can be checked by applying a thin coat of lapping paste to the valve seat and a coat of dye to the valve. Lap the valve lightly and check the pattern remaining on the valve.

2. On most models, the valve seat should be 1.0–1.5mm wide and must be of the same width all the way around. The seat contact area must be centered on the valve bevel.

3. If the valve seat does not conform to these standards, or if it is badly pitted, or if new guides have been fitted, the seat should be recut.

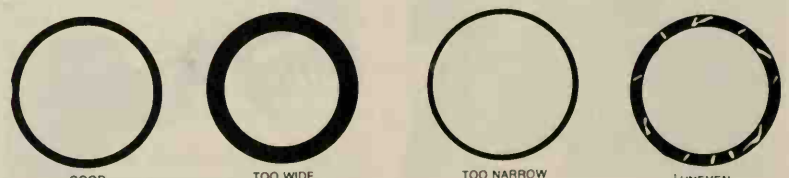
Lapping

1. Valves must be lapped into their seats if the valve seat has been recut, a new valve has been fitted, the leakage test shows poor sealing, or minor pitting on the seat or valve are noted.

Valve seats: A, too wide; B, too narrow; C, too low; D, too high

It should also be done as a routine operation on high-mileage machines.

2. Clean off all carbon build-up on the surface of the combustion chamber. Place three small dabs of valve lapping paste around the circumference of the valve head and place the valve into the guide.



3. If you have a lapping tool, use it as the manufacturer directs. Usually, the tool will turn the valve back and forth while rotating it around the seat at the same time. Do not use excessive pressure during the operation.

If you do not have such a tool, a piece of

Hand lapping the valves

Valve seat patterns

thick fuel line placed over the valve stem works just as well. Turn the valve back and forth and rotate it to a new position every few seconds.

NOTE: *Check the condition of the valve face and seat frequently. When a smooth, even finish is evident, stop lapping. Excessive lapping may lead to a pocketed valve.*

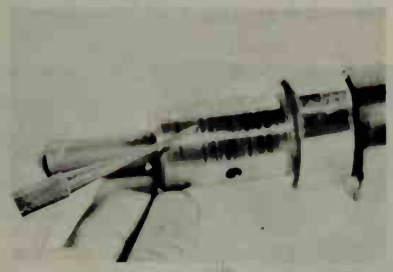
4. Remove the valve and clean it thoroughly. Remove any traces of lapping compound from the seat and the combustion chamber. Swab out the guide with a cotton swab soaked in a solvent. Squirt a little oil into the guide so that is may carry away any particles inside.

5. Check the width and condition of the valve seat. If seat width is too narrow or too large, or if width varies, or if pitting still remains, the seat must be recut and the valve replaced.

Valve Train

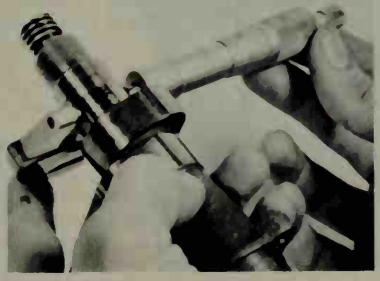
On pushrod engines, tappets and pushrods should be checked as follows:

1. Check the condition of the tappet pad which contacts the camshaft. It must be smooth and without score marks. If damaged, the tappet should be replaced, since in most cases the pad is specially hardened and grinding the pad flat is therefore not recommended. Check the pushrod cup for damage. Check the sides of the tappet for scoring, and replace it if damaged.



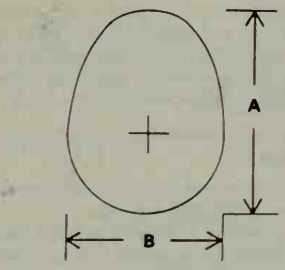
2. Pushrods must be perfectly straight, as is obvious. Also check the condition of the pushrod ends, making sure that any ball end is perfectly smooth and not discolored.

Camshaft



1. Closely inspect the cam lobes for pitting, wear or scoring, or discoloration. Any imperfections will require replacement of the camshaft. Score marks on the lobes may not be removed by an abrasive method as this will affect the valve timing.

2. Check the camshaft journals in the same fashion. Bearing surfaces must be without flaws.



3. Measure the diameters of the journals.

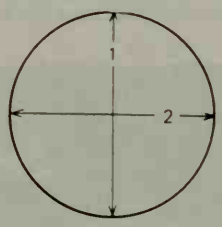
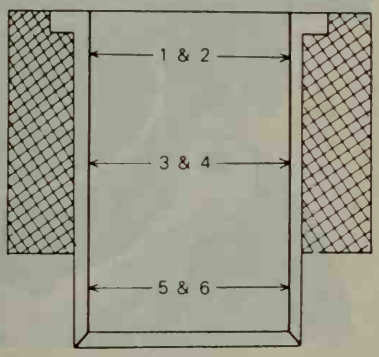
4. Check the height of each cam lobe.



5. Check the camshaft for a bent condition.



Cylinder and Piston

1. Make a visual inspection of the cylinder bore, noting any imperfections. The cylinder walls should be uniformly smooth.

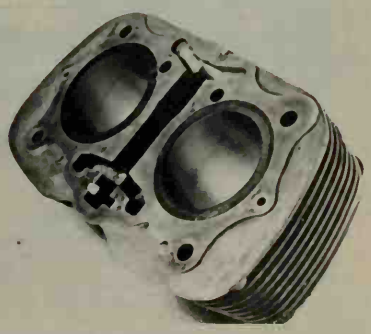
Perform the following measurements to determine the extent of cylinder wear. If the cylinder walls are chromed, wear beyond the service limit requires replacement of the pistons and cylinders. On the much commoner iron cylinders, boring is the usual remedy. If boring is necessary, obtain the replacement pistons first, and bore the cylinders to the piston diameter plus the standard piston clearance. After boring, hone the cylinder(s) to produce a light cross-hatch pattern.

2. Measure the diameter of the cylinder(s) at the top, middle, and bottom of the bore

Cylinder measurement points

making all measurements in the same direction (i.e. from the front to rear of the cylinder). The difference between the smallest and largest of the three readings is the cylinder taper. The largest of the readings is to be compared with the bore service limit if given for your machine.

3. Turn the micrometer 90° and measure the bore at the top, middle, and bottom as before. The difference between readings taken in different directions yields cylinder ovality.



4. Make a visual inspection of the piston(s). Scoring, scuffing, or seizure marks on the piston skirt may be removed with a fine grade of crocus or emery cloth if not severe. Sanding should be done to produce a cross-

hatch pattern. If the score marks are more than about ½ in. wide, or if the skirt has deep scratches, the piston(s) must be replaced.

5. The rings must be free to move in their grooves. If they cannot, either they are carbon clogged (which necessitates removing the rings and cleaning out the grooves), or metal has been pushed into the grooves by a piston seizure. In this case, piston and rings must be replaced. Since it is virtually impossible to remove frozen rings without breaking them, new rings will usually be required if the present set are carboned up.

6. Measure the diameter of the piston(s) at the bottom of the skirt perpendicular to the wrist pin, or at the specified distance from the bottom if given. Compare the reading with the standard piston diameter, if given, and with the bore diameter.

7. If possible, measure the inside diameter of the wrist pin holes. Check the fit of the wrist pin in the piston. It should be a tight fit with no play at all evident. If the wrist pin fits loosely in the piston, either the piston or the pin is worn.

8. Check the diameter of the wrist pin at three places along its length. Check for stepwear.

Replacement of the pin is also required if it is in any way scored or discolored.

9. Check the fit of the wrist pin in the connecting rod small end. There should be no vertical play. Check the condition of the small end, noting any scoring or discoloration. Some motorcycles have a replaceable bush in the con rod small end eye, while on most, the wrist pin rides directly on the rod. Movement of the wrist pin or scoring of the small end will require replacing the bush or rod itself.

Piston Rings

Two checks to be made to the piston rings are side clearance and ring end-gap.

1. Side clearance is checked with the rings installed on the piston. Insert a feeler gauge of the proper thickness between the ring and ring groove. If the clearance is too large, the rings or grooves are worn. If not sufficient, metal may have been pushed into the grooves due to a piston seizure. Check that the grooves are not just carboned up before

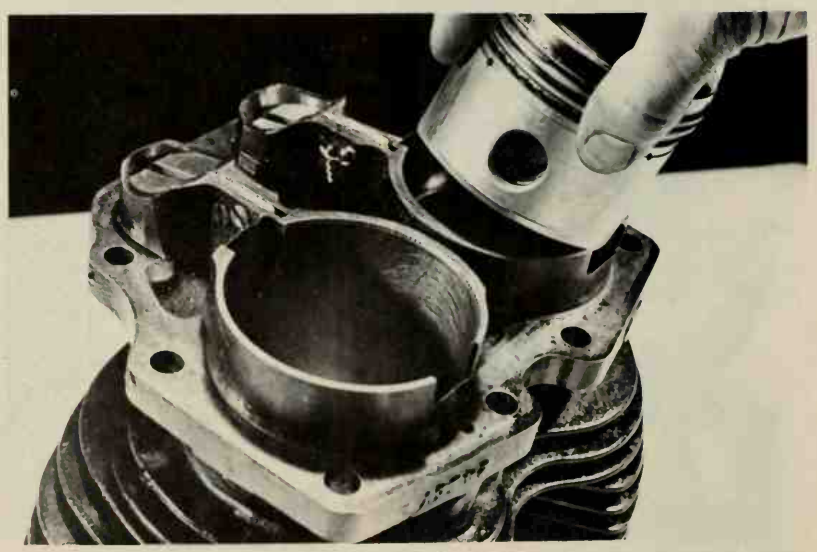
Checking ring side clearance

replacing the piston. If new rings do not bring the clearance to the proper value, the piston must be replaced.

2. To remove rings from a piston, a ring expander is recommended. Removing the rings by hand risks breaking them.

3. To check ring end-gap, ensure first that the bore is not worn to the service limit. Place each ring, in turn, into its own cylinder at the bottom of the bore and push it in an inch or more. Use the piston to correctly align the ring in the bore.

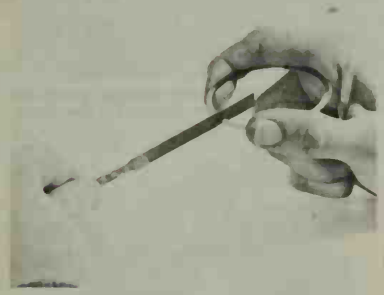
NOTE: *Oil the rings before this operation to prevent scratching them on the bore*



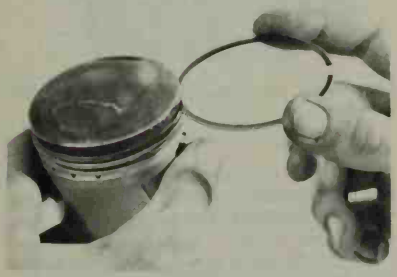
Removal and installation of rings should be done with a ring expander

Measure the end-gap with a feeler gauge of the proper thickness. If the endgap is larger than the given value, replace the rings as a set. If the measured gap of new rings is larger than the standard value, the cylinder is worn and should be bored to the next oversize.

If new rings are being checked, and the end-gap is too small, the ring ends must be filed. Hold the ring steady, closing the ends over a thin, flat file. Do not squeeze the ring, or allow the file to slip out from the ring ends, as this is the easiest way to break it. A few strokes of the file will increase the end-gap.



Measuring ring end-gap



Use the piston to align the ring in the bore

CAUTION: *Do not make more than a few strokes before rechecking the end-gap. It is easy to remove too much metal.*

4. Roll each ring around the piston in its own groove. If a ring sticks or binds in a groove, the grooves must be cleaned. If this does not remedy the problem, replace the piston.

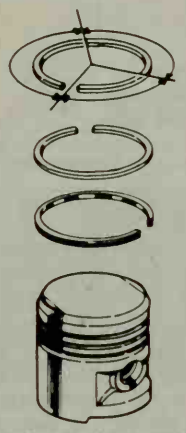
Filing ring ends

Roll the ring around the groove to check for free movement

Cleaning out piston ring grooves

5. Before fitting new rings, the ridge at the top of the cylinder must be removed. This ridge forms on all cylinders eventually because the top compression ring never reaches the very top of the cylinder, while the rest of the bore wears slightly. Fitting new rings on high-mileage machines without removing the ridge may cause the top compression ring to break when it contacts the ridge.

6. The cylinder(s) should be honed before fitting new rings. Honing should be done to put a light cross-hatch pattern on the walls.

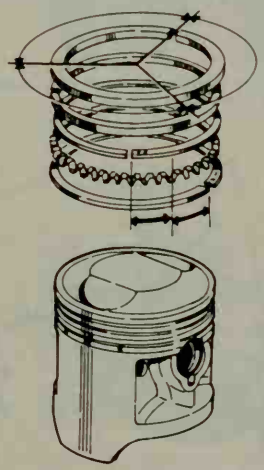


Piston Installation

1. When fitting rings to pistons first note that the two compression rings are usually not interchangeable.

2. Rings are always installed with the marked side *up*. On some rings this is marked "Top," while on most others the top side is indicated by the manufacturer's mark near the ring end.

Rings are always installed with the stamped mark facing up



Stagger ring end-gaps. Note piston position mark

3. Ring ends must be staggered around the piston since alignment would cause compression and oil leaks. Unless specific instructions to the contrary are given, on models with a single-piece oil ring, arrange the end-gaps 120° apart. On models with a two-rail oil ring, the end-gap of the rail expander should be 120° from the gap of the lower compression ring and the end gaps of the oil rails should be about 45° on either side of the expander gap.

In both cases the rings should be arranged so that none of the end gaps is at the very front or back of the piston or directly above the wrist pin hole, unless the manufacturer specifically states to do so.

4. In almost all cases the piston crown is marked for proper installation. If "IN" is stamped on the crown, it must be located on the intake side, and the opposite is of course true if "EX" is marked. On pistons marked with arrows, the arrow almost always points towards the exhaust port.

Ring end-gap positions with three piece oil ring

5. Be sure to use new wrist pin circlips and oil the piston rings and skirt before fitting the cylinder. Locate the circlips so that their end gap does not align with the wrist pin hole cut-out, if there is one.

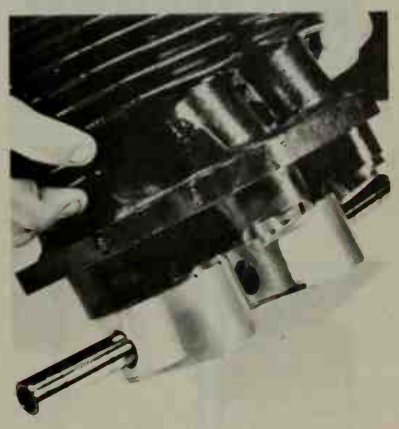
6. When the cylinder is installed, it is necessary to pay some attention to the piston rings so that they will enter the bore without breaking. Many machines have a beveled area at the base of the cylinder which makes installation easy. On others, the rings must be compressed as they enter. On single-cylinder motorcycles this can be done with the fingers, but on twins and multis, ring compressors must usually be used.

7. A way around the use of ring compressors can be used on some twins. Using this method, the pistons are installed in the bores as far as the wrist pin holes, the inside wrist pin circlips having already been fitted. The cylinder block is then supported above the connecting rods while the wrist pins are slipped in.

If this method is used, care must be taken not to install the pistons backwards.

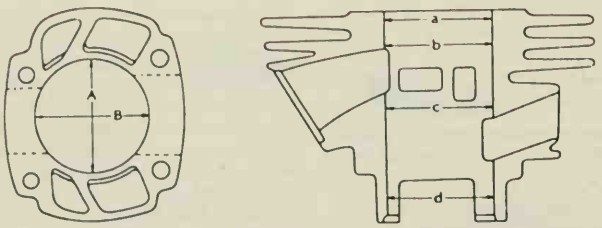
TWO-STROKE

Cylinder Head



1. Decarbonize the cylinder head, piston crown, and exhaust port by scraping off deposits from these surfaces with a blunt knife blade or something similar. After as much carbon as possible has been removed in this manner, finish up with #400 grit sandpaper.

NOTE: *It is advisable to exercise extreme caution when decarbonizing these components to avoid scratching or scraping of the metal itself. Therefore, sharp instruments should not be used for decarbonization.*

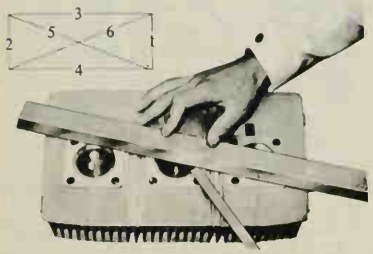


2. Inspect the spark plug hole in the head, making sure that it is clear of carbon particles and the like. The threads may be cleaned out with a tap if necessary.

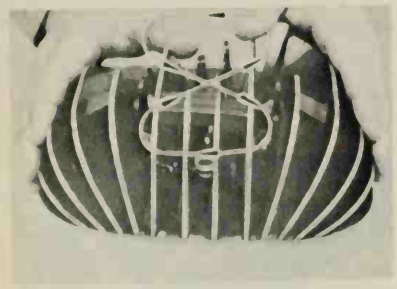
3. Inspect the combustion chamber surface for smoothness. It should be free of any major surface imperfections as might have been caused by a botched decarbonization job.

4. Check that the cylinder head mating surface is as smooth as possible. Clean off any foreign matter with a very fine abrasive emery paper. Place the head on a known flat surface, such as a piece of glass to check it for warpage.

One method of installing the cylinder without ring compressors

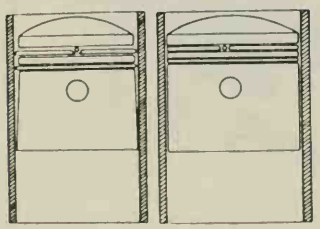


Cylinder bore measurement points



The head should contact the glass all around. Using very thin feeler gauges, try to slip them in between the cylinder head mating surface and the glass. Ideally, you would not be able to do this. If you can, however, it indicates that the head is slightly warped. A straight-edge can also be used.

Head warpage can sometimes be remedied, or mating surface imperfections removed, by placing the head on a perfectly flat surface which has an amount of valve grinding paste or a sheet of emery cloth on it. The head can then be worked back and forth, or lapped, in a figure 8 pattern, until the warpage is eliminated or the imperfections removed.



CAUTION: *The most important consideration is that the lapping operation not be carried to extremes. It is very easy to remove too much metal from the head.*

When lapping the head, move it in a figure-eight motion

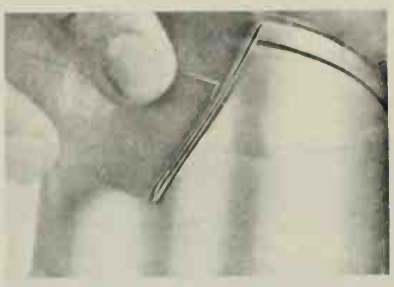
5. If hand lapping does not restore the flatness of the mating surface, it can be done on a machine designed for this purpose.

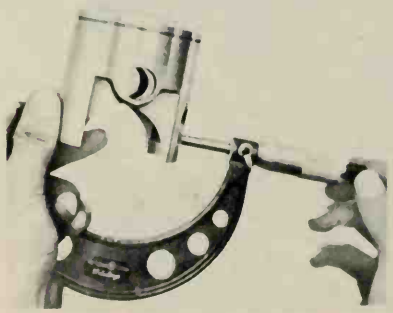
Cylinder and Piston

1. This piston is "cam-turned" in the same way, and for the same reasons, as the four-stroke piston described in the preceeding section.



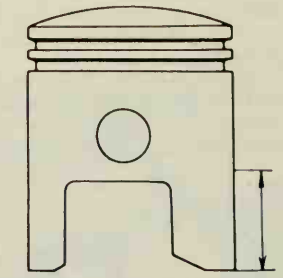
2. Wear of the cylinder bore is checked by making a series of readings at three or four places along the bore in one direction, and then turning the gauge 90° and measuring at the same places. The measurements are taken at the top, middle, and bottom of the bore, but most manufacturers give exact points at which the readings are to be taken.

3. Make a visual inspection of the piston. The skirt must be free of scoring or seizure marks. If present, it may be possible to save the piston by polishing the damaged area with emery or crocus cloth. Sand lightly to produce a cross-hatch pattern.



If the scored area was wider than ½ in., or if deep scratches remain after sanding, the piston should be replaced.

4. Piston diameter is measured perpendicular to the wrist pin near the bottom edge of the piston skirt. Some manufacturers give a precise measurement point.



Maximum allowable piston-to-cylinder

Measuring piston diameter

Most makes give a certain distance above the edge of the skirt at which diameter is measured

After boring, the edges of all ports should be bevelled

clearance for most models is 0.1mm (0.0039 in.), and after this point the cylinder must be bored to the next oversize, unless it is a chrome-plated bore.

If the cylinder is bored, it is necessary to chamfer all the edges of the ports with a file to remove any sharp edges.

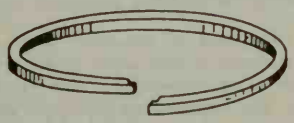
5. Piston rings must be free to move on the piston. If frozen, they may be carbon-clogged, or the ring grooves may have been ruined by a seizure. If carbon-clogged, it will only be necessary to replace the rings, but deformed grooves necessitate replacement of the piston.

6. Check ring side clearance by inserting the proper size feeler gauge between the ring and the bottom of the ring groove. If used rings do not have the correct side clearance, replace them and recheck. If new rings show the incorrect clearance, replace the piston.

7. To check ring end-gap, remove the rings from the piston by spreading the ends with the thumbs. After removal, check the rings for a twisted or warped condition. Such rings must be replaced.

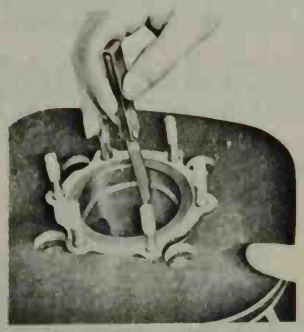
Some manufacturers give a "free end-gap" specification. As the name implies, this is a measurement of the ring end-gap as the ring sits after removal from the piston and is not to be confused with the more common "ring end-gap" which is measured with the ring in the cylinder bore (see Step 8, following). "Free end-gap" should be measured after a ring has been removed from its piston, and is intended to indicate whether the ring has been deformed by removal.

8. Place each ring, in turn, into the top or bottom of its bore and push it in an inch or so using the piston skirt. This will ensure that the ring is aligned perpendicular to the cylinder wall.

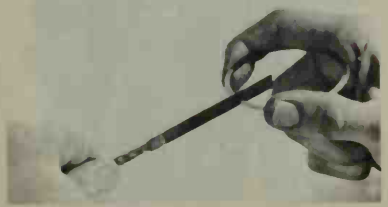


First check that the ring is contacting the cylinder wall at all points. Place a piece of white paper beneath the cylinder and see if anything is visible between the cylinder wall and the ring. If you can see the white paper,

Checking ring side clearance



Removing a piston ring



Check for warped rings

the ring is not touching the wall either because the ring is worn or deformed, or because the cylinder itself has become ovalized through wear.

9. Check ring end-gap with the proper feeler gauge. If the gap is larger than the given specification, the rings must be replaced. If too small, hold the ring carefully, closing both ends against a thin, flat file. After a few strokes of the file, recheck the gap.

Decarbonizing ring grooves

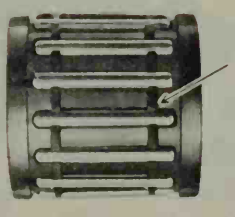
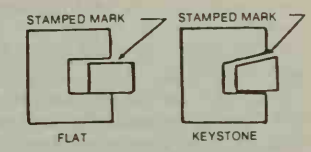
CAUTION: *Check the end-gap frequently during this operation as it is easy to remove too much metal. Do not allow the file to slip out while filing as it is very easy to break the ring in this way.*

10. Clean out the piston ring grooves. Use a small screwdriver or thin instrument for this operation, but take care that the metal of the piston is not scratched.



Plain-type ring grooves may be cleaned out with a piece of broken piston ring. Other types of grooves, however, should not be cleaned in this manner, as the groove may be scratched.

11. Check the wrist pin for discoloration or step-wear. If damaged in this manner, the wrist pin and needle bearing (if fitted) should be replaced.



12. Lightly oil the wrist pin and insert it into the piston. There should be a fair amount of drag on the wrist pin while at-

tempting to push it in by hand. If the pin goes in easily, or can be turned with ease after insertion, either it or the piston will have to be replaced.

13. Insert the wrist pin into the con rod small end. Check for vertical play. If there is any at all, the wrist pin and the small end bearing must be replaced.

14. To check for connecting rod straightness, fit the piston, minus the rings, onto the connecting rod and install the wrist pin. Install the cylinder. The piston should be dead center in the cylinder bore. If moved to either side, it should return to the center position after the engine is turned over once or twice. If it does not, or if it appears to be to one side or the other in the bore, the connecting rod is probably bent.

15. On models with caged needle bearing small ends, check the condition of the needle bearing. Replace it if the needles are pitted, discolored, or otherwise damaged, or if the wrist pin or piston rings are replaced.

Piston Installation

1. Piston rings may be "plain," "keystone," or "L-shaped" depending on make and model and in some cases the top and bottom rings may not be interchangeable.

2. Rings are always installed with the identification marks facing *up*.

3. Be sure that the ring end gaps are located on either side of the locating pin in the ring groove.

4. The piston must be properly installed on the rod, and in most cases an arrow is stamped on the piston crown. This must point towards the exhaust port. Some models may have other ways of determining piston position.

5. Always use new wrist pin circlips. Position the circlip end-gaps so that they do not align with the wrist pin hole cutout.

CLUTCH

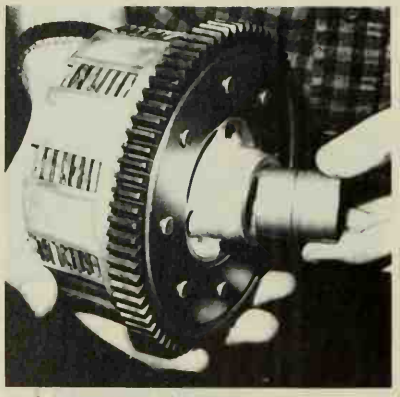
1. Check the condition of the friction plates noting any scoring or damage to the material. Check the condition of the engaging tabs. Measure the thickness of the plates and compare to the standard specification.

Friction plates are replaced in sets.

2. Check the steel plates for scoring or discoloration. Check plate warpage.

3. Check clutch spring free length and replace springs as a set if any one spring is compressed.

Checking clutch spring free-length



Checking a steel plate for warpage

4. Check the clutch housing for indented wear caused by the engaging tabs of the plates. Indentations here, and minor wear to the engaging tabs, can usually be remedied with an oilstone or file. Indentations on the housing may catch the plates and not allow them to disengage properly, and should therefore be removed, or the housing replaced.

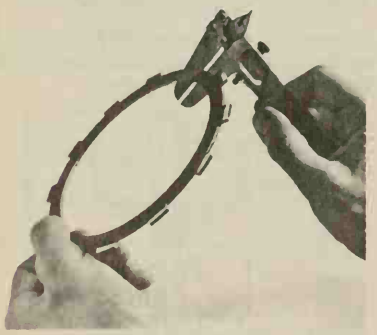
5. Either the clutch hub or the housing will engage the shaft splines, depending on the design of the clutch. Check for excessive backlash, and damage or wear to the clutch and shaft splines.

6. Check the clutch housing gear, if applicable, for wear or damage to the teeth. If the gear teeth are worn, check those of the primary gear as well. Gears which mesh should always be replaced in pairs. If the clutch is chain-driven, check the teeth for hooking or wear in the same manner as for countershaft and rear wheel sprockets.

7. Check the clutch pushrod, if applicable, for a bent condition. Replace or straighten it if bent.

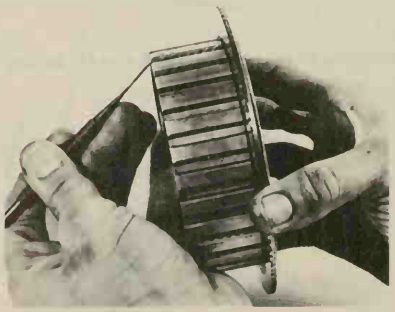
Inspect the clutch hub bushing for wear

8. The clutch lifter mechanism is not ordinarily subject to wear. However, the component should be thoroughly cleaned, especially on those models where it shares the crankcase cover with the engine sprocket, and should be well lubricated.



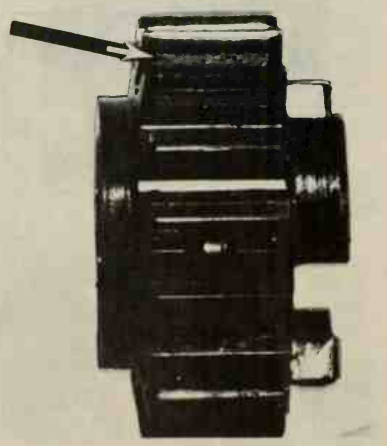
TRANSMISSION

1. Gears may be inspected in place on their shafts on models which allow the gear clusters to be removed as a unit. On many makes, the transmission gears are located with circlips. Once removed, these circlips should be replaced with new ones. If disassembly of the gears is undertaken, lay out each circlip thrust washer, shim, or gear in order to facilitate installation.



2. Check each of the gears for heat damage (discoloration), or for chipped, broken, or worn teeth. Pitting or wear of the hardened surface of the teeth will be most obvious at the very base of the teeth. Replace any gear showing such signs, and replace the gear with which it meshes as well.

3. Check the inner splines on gears so equipped, and replace the gear if the splines are worn or broken. Inspect the corresponding splines on the transmission shaft. Check for excessive play of the gear(s) on the shaft(s).



4. On gears with a plain bore, check for scoring. Check that the gear fits easily on the shaft, and turns freely, but it must not have

Checking gear backlash

any up-and-down play. On gears with replaceable bushings, check for score or scratch marks, discoloration, etc., and replace the bushes if necessary.

5. Check the engaging dogs on gears which have them. Dogs must not be worn, chipped, or borken, or the gear must be replaced.

6. Check that the transmission shafts are not bent. Check the condition of the splines, surfaces, and bearing journals, if applicable.

7. Check the transmission shaft bearings. If ball or roller bearings, check for discoloration, damage to the balls or rollers, noisy or halting rotation, etc. If plain-type bearings or bushings, check for score marks.

8. If the means are available, check gear backlash. If the backlash for any two gears is excessive, both gears of that set must be replaced.

9. During reassembly, check gear sideclearance if applicable.

Inspect each gear for worn or chipped engaging dogs

SHIFTER

To change gears, it is necessary to move certain gears back and forth on their shafts, and this is accomplished by the use of "shift forks." The shift forks are themselves moved either by a "shift drum" or a "camplate," the later being found primarily on British motorcycles.

1. Check shift forks for wear at the ends of the fingers. Some models have a finger thickness specification given. Check that the fingers are not chipped or bent. Check the shifter shaft or shift drum bore in the fork for wear. The forks should be a close fit on the shaft or drum. Check the shift fork pin (which rides in the drum or camplate grooves) for chipping or other damage.

2. If the transmission has a shift fork shaft, check that is is not bent by rolling it along a flat surface.

3. If a camplate is fitted, check that it is perfectly flat. Check for wear to the grooves. Check the detent plunger notches for condition.

4. If a shift drum is fitted, check the shift fork pin grooves for wear or damage. If the shift fork(s) ride on the shift drum, check for wear at that point. Check for wear of the bearing surfaces, if applicable.

FUEL SYSTEM

The fuel system is made up of the carburetor(s), fuel filter, and air filter. The following information encompasses the great majority of components currently in use.

Of course, in actual practice, carburetors are not quite that simple. The basic unit described above has no provisions for throttle control, cold starting, or the varying needs of the engine.

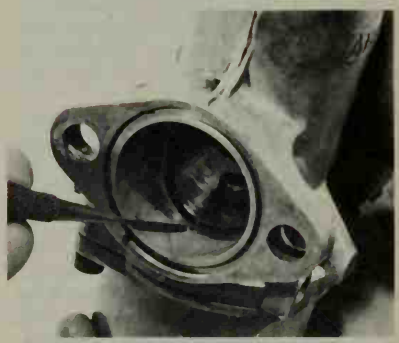
The operating stages of a "real" carburetor are described below.

Construction

Most carburetors consist of a one-piece body cast from cheap pot metal, although some "racing" units are made from more expensive materials such as magnesium. The body incorporates the venturi, a bore for the movement of the throttle slide, and provides a mounting point for various fuel and air jets.

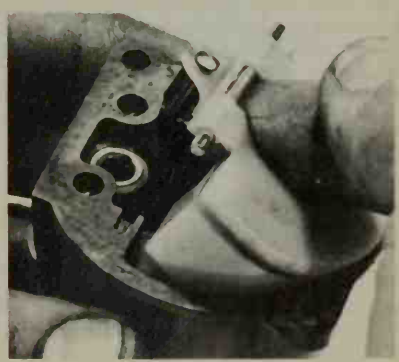
Primary air passage, flanked by idle air passage on left

In addition, the body is drilled with a number of fuel and air passages. Among these are the primary air passage, pilot air passage, and pilot outlet or by-pass.



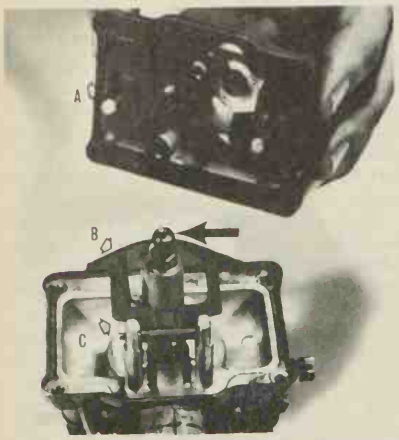
The *primary air passages* can usually be found just beneath the carburetor intake, and is drilled through to the needle jet. The air taken in through this passage helps to atomize, or mix, the gasoline passing through the needle jet before it enters the venturi. Unless the gasoline is atomized, raw fuel will reach the combustion chamber, resulting in wet-fouled spark plugs, inefficient combustion, and generally poor operation.

The *pilot air passage* is located alongside the primary air passage on most carburetors. The air taken in through this drilling is used for idle and low-speed operation.



The *pilot outlet* is a very small drilling which can be seen on the engine side of the throttle slide bore. The fuel/air mixture for idling pass through here and then to the engine.

The carburetor body also has a place for the attachment of the *float bowl*. The float bowl houses the float assembly and carries the carburetor's gasoline supply. A part of the float assembly is the float valve which usually consists of a small needle and a needle seat. The floats rise and fall according to the amount of gasoline in the float bowl, alternately pressing the needle against its seat and releasing it, thence controlling the fuel flow. The float bulbs may be made of various materials. Most early carburetors used brass bulbs, but plastic has been used more frequently in recent years. Float needles can be plastic, brass, or neoprene-tipped brass, the last proving most effective. Needle seats are almost always brass, and on most carburetors can be unscrewed for cleaning or replacement.



The great majority of modern carburetors mount the float bowl directly beneath the carburetor body. In this position the fuel supply surrounds the main jet ensuring an accurately metered supply of fuel during ac-

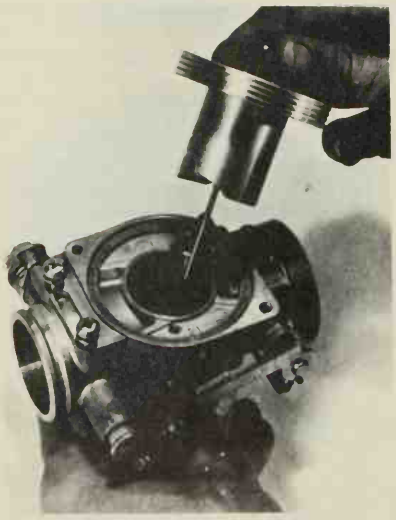
celeration, braking, or banking to either side. This type of carburetor is usually known as "concentric." Not all carburetors were constructed in this manner, and separate float bowl carburetors were the rule for many years.

The *throttle slide* is the chief metering component of the carburetor. It is controlled directly by the throttle cable which runs to the twist grip on direct-control type carburetors. On "CV" units, the throttle cable opens and closes a throttle plate, and the slide proper opens and closes by venturi vacuum (this is explained later).



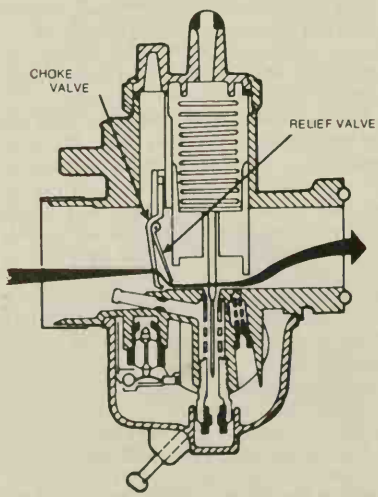
The throttle slide determines the size of the carburetor venturi and therefore meters the amount of air in the fuel/air mixture at most of the operating range. Additionally, the *needle* or *jet needle* is attached to the slide. This needle works in conjunction with the *needle jet* and determines the amount of gasoline allowed to pass into the engine primarily in the mid-range.

The throttle slide is cylindrical in most carburetors, although there are examples of "square slides" such as used by some Dell 'Orto carburetors. The slide has a cutaway at the intake side of the carburetor to allow the entry of air in sufficient quantities to mix with the gasoline when the throttle is closed. The higher the cutaway, the leaner the mixture will be when the slide is just opened. If the size of the cutaway is not matched to the other metering components and the particular needs of the engine, the transition from idle to the main metering system will be greatly impaired. This is a particularly critical period, since the load on the engine is changing as the clutch is engaged, and smooth starts from a dead stop must be considered a matter of safety in many cases.

Throttle slide cutaway

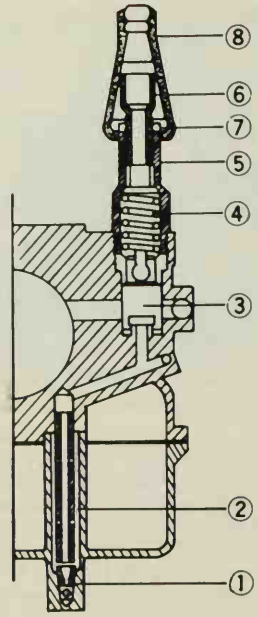
Formerly, throttle slides were cast from the same material as the carburetor body, but this was found to cause greatly accelerated wear on both slide and body. Today, the slide is commonly steel, often chromed, bringing wear into more acceptable limits. In CV carburetors, where the slide must be moved by venturi vacuum, the slides must be light in weight so light alloys are used.

CV carburetor slides are light in weight and must be closely fitted to the carb bore



OPERATION

The operation of a practical carburetor can best be described by dividing it into five circuits, and the components which control each one.



Direct-Control Carburetor

STARTING CIRCUIT (0 THROTTLE OPENING)

The engine needs a rich mixture for starting when cold. Since this need is only temporary and the mixture must be balanced when the engine warms up, a manually operated

"choke" is incorporated into most carburetors and is controlled by the operator.

There are various ways of creating this rich mixture. The most simple is to reduce the amount of air available to the carb by closing off the mouth with a plate. This method is most often found on Honda motorcycles and on some others as well.

On some units, notably the Amal Monoblocs and Concentrics, a temporary rich mixture is obtained by flooding or overfilling the float bowl. "Ticklers" are provided on the carburetor. When pushed, they depress the float, allowing the float needle to rise from its seat. The fuel level in the float bowl then exceeds its normal level and rises through the jets into the venturi where it provides a rich starting mixture.

Other carburetors, such as Mikuni and Dell'Orto use a refined version of the tickler. A starter jet is fitted which is activated by a cable or lever. When activated, the jet is opened (in most cases a spring-loaded plunger does the opening and closing), and fuel from the float bowl can bypass the normal fuel jets and pass into the carburetor bore.

Once the engine is started and warmed up, the choke is switched off, and the fuel/air metering is turned over to the idle circuit components.

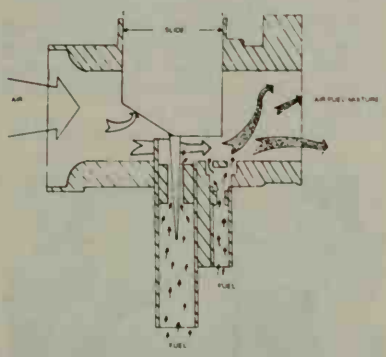
IDLE CIRCUIT (0–⅛ THROTTLE OPENING)

At idle under normal operating conditions, the engine requires very little fuel and air. It does, however, require more accurate metering than pure venturi action can provide while the engine is turning relatively slowly and intake air velocity is low.

The idle circuit on most popular carburetors consists of a pilot jet, pilot air passage, and the throttle slide.

Fuel is provided by the float bowl. The

amount of fuel is metered by the pilot jet, while air is taken in through the carburetor venturi and passes under the throttle slide (which is almost, but not quite closed at this point).

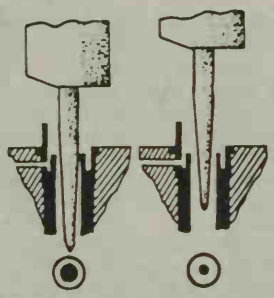


Because the idle mixture is so crucial, it is possible to adjust the mixture to compensate for changing conditions so that a good idle is always maintained. For this reason a pilot screw is fitted to most carburetors. The pilot screw is really a tapered needle and is fitted to an air or fuel passage. Turning the screw in or out will change the amount of fuel or air allowed to pass, and hence the mixture. On some carburetors the pilot screw is fitted directly to the pilot air passage and is sometimes called the "pilot air screw." On carburetors of this type, the amount of fuel entering the idling engine is determined by the size of the pilot jet alone, and the amount of air is varied to meet changing conditions.

On other types of carburetors, it is the amount of air which is fixed by the size of the pilot air passage. On these carburetors, the pilot screw changes the amount of *fuel* passing into the engine.

In operation, piston suction creates a low-pressure area behind the throttle slide. To equalize this low pressure, air rushes through the pilot air passage, mixes with fuel from the pilot jet. This mixture is bled into the carburetor's intake tract through the pilot outlet. The air coming in under the throttle slide is added to this mixture and delivers it to the combustion chamber.

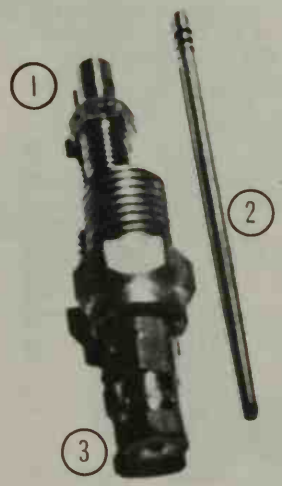
LOW-SPEED CIRCUIT (⅛–¼ THROTTLE OPENING)



This circuit uses the same components as the idle circuit. There is, however, an increase in the airflow as the throttle slide rises, and in fuel flow as the needle begins to come out of the needle jet. This effects a transition to the mid-range circuit, since the increased amounts of fuel and air delivered by the needle jet and the venturi overshadow the smaller amounts coming from the pilot outlet, eventually eliminating the idle circuit from the metering system.

Carburetor low-speed operation

MID-RANGE CIRCUIT (¼–¾ THROTTLE OPENING)



In this circuit, air is supplied by two sources: the venturi and the primary air passage. The more important reason for the air going through the primary air passage, however, is that it mixes with the gasoline in the needle jet (the needle jet has a number of holes drilled in it), and this helps to atomize the fuel before it enters the venturi.

Needle/needle jet operation as the throttle slide is raised

Fuel is supplied by the float bowl and metered by the needle jet and needle. The needle jet on most carburetors is located just above the main jet and works in conjunction with the needle suspended from the throttle slide.

As the slide rises, the air flow through the carburetor is increased, and at the same time the tapered needle allows more and more fuel to pass through the needle jet.

Mid and high range metering: 1, needle jet; 2, needle; 3, main jet

HIGH-SPEED CIRCUIT (¾-FULL THROTTLE)

The throttle slide has been lifted clear of the venturi, and no longer controls the amount of air. By the same token, the needle has lifted out of the needle jet, and no longer controls the fuel supply.

Venturi action takes over completely. The amount of air sucked into the engine is determined by the size of the venturi, and the amount of fuel delivered by the size of the main jet. The only other part of the system which still has a significant effect is the primary air passage which continues to aid fuel atomization.

It should be understood that the operating ranges of the various metering circuits overlap somewhat, so there is a gradual, rather than an abrupt, transition from one to another as the throttle is operated.

The relative independence of the various circuits, however, should explain why it is fruitless to make random changes in carburetor settings without first determining the nature of the problem, and the range in which it occurs.

Accelerator Pumps

Some direct-control carburetors now used on four-stroke motors incorporate accelerator pumps which squirt a stream of raw gasoline into the venturi whenever the throttle is opened. The pumps usually consist of a throttle slide-activated plunger which takes fuel directly from the float bowl, bypassing the normal metering components.

Accelerator pumps are incorporated to aid the transition from the idle system to the main metering system. Throttle response is therefore much improved. One disadvantage of the system, however, is that it may have an adverse effect on fuel economy.

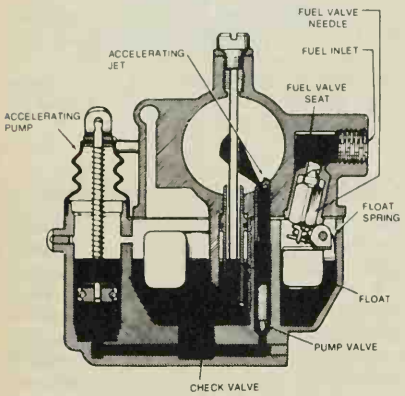
Constant-Velocity Carburetors

The constant-velocity carburetor is basically the same as the direct-control type carburetor, except that the throttle twist-grip is not connected directly to the throttle slide. Instead, in the CV carburetor, the throttle grip and cable are connected to a throttle plate located between the intake manifold and throttle slide. As the throttle plate is opened, the manifold vacuum evacuates air from the top of the slide chamber through a passage in the slide. Consequently, on demand from the engine, the slide is raised and more air is admitted, and the tapered needle is proportionally lifted out of the jet tube to admit more fuel.

The term "constant-velocity" (or constant vacuum) refers to the speed of the air passing over the main jet tube and the vacuum in the carburetor throat which remains constant due to the movement of the piston in relation to the vacuum. As the engine demands more air and the manifold vacuum increases, the slide responds by lifting in proportion to the vacuum. Thus the carburetor air speed and vacuum remain constant, because an increase in vacuum means an increase in slide lift, which in turn increases the amount of air passing through the carburetor by altering the size of the air passage (venturi), and compensating for the increased engine demands with a larger flow of air. A constant vacuum indicates a constant-velocity, and vice versa.

Throttle-Plate Carburetors

The "throttle-plate" carburetor is little different in theory from the throttle-slide types considered above except, of course, that there is no moving slide. In its place is a flat plate which pivots as the twist-grip is rotated to increase the size of the carburetor throat and allow progressively more of the fuel/air mixture to enter the combustion chamber.



Unlike the throttle-slide carburetors described above, the throttle-plate units do not usually have well-defined mid-range circuits, and are best described by breaking the operation down into "low-speed" and "high-speed" circuits.

The Bendix 16P12 carburetor is typical of this type and is used to illustrate the follow-

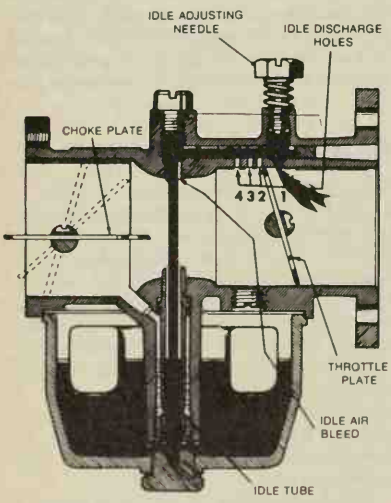
ing explanation. This carburetor was used on most Harley-Davidson V-Twins after 1970, with the exception of late models fitted with a very similar Keihin unit.

STARTING CIRCUIT

A choke plate on the intake side of the carburetor closes off the mouth to yield a rich mixture needed for starting. A hole in the choke plate allows some air to enter to prevent flooding the engine. In addition, an accelerator pump is fitted which injects a stream of gasoline into the venturi when the throttle is opened.

Starting circuit

LOW-SPEED CIRCUIT



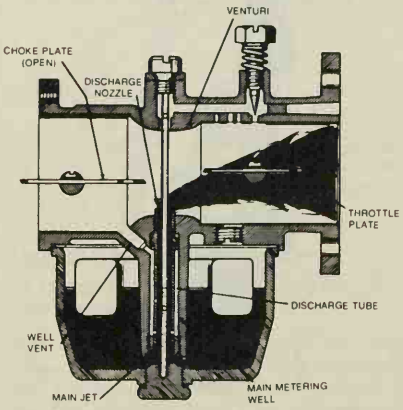
There are three or four idle discharge holes located at the top engine side of the venturi. The main idle discharge hole (No. 1 in the illustration) is variable in size as it works in conjunction with a tapered idle adjusting needle. At idle, the throttle plate stop screw holds the throttle plate open just enough so that this passage is able to discharge its fuel into the engine.

Drawn by piston suction, gasoline rises from the float bowl through the idle tube. As the fuel passes the idle discharge holes (Nos. 2, 3, and 4), air is drawn in and mixed with it. The mixture is then bled into the intake port through the idle hole No. 1.

The mixture is determined by the idle adjusting needle. If the needle is turned IN, the mixture will be leaned out, and it will be richened if the needle is turned out.

As the throttle is opened slightly, the other idle discharge holes are exposed in turn, each allowing progressively more fuel and air into the intake port.

Eventually, the throttle plate is opened enough so that engine suction is powerful enough to draw gasoline from the main discharge tube and the transition to the high-speed circuit begins.



Low-speed circuit

HIGH-SPEED CIRCUIT

The high-speed circuit begins when all idle discharge holes are exposed, and can no longer supply sufficient gasoline and air for the engine's needs.

As the throttle plate is opened the velocity of the incoming air passing through the venturi is increased, and, as this happens, this air exerts an increasingly powerful suction on the gasoline in the discharge tube just below the venturi. This gasoline is already partially atomized by the air drawn through the well vent.

When the throttle is fully opened, the amount of air in the mixture is determined by the size of the carburetor venturi and the amount of fuel by the size of the main jet.

High-speed circuit

CARBURETOR REBUILDING

The following guidelines are applicable to all carburetors in use today. For specific disassembly procedures, refer to the individual model section.

1. After disassembly, clean all metal parts with a solvent or a commercial carburetor cleaner. Blow dry.

CAUTION: *Clean carburetors in a solvent which is safe for plastic. Many units are fitted with non-removable parts of this material which may be damaged if a harsh solvent is used.*

2. Use compressed air to clean out the air and fuel passages in the carburetor body. On some units, the primary air and pilot air passages may be large enough to permit the entry of a cotton swab if necessary to remove dirt and varnish.

3. Check the main body casting carefully for vibration or stress cracks. If the carburetor is bolted to the cylinder head or manifold, check the mounting flange for warpage by placing a straight edge across it or by placing it on a flat surface such as a piece of glass. The flange must be very close to a perfectly flat condition, or possible air leaks may be the result. Minor warpage or surface imperfections can be corrected by placing a piece of emery cloth on the glass and working the carburetor flange on it. Move the carburetor in a figure-8 motion. Alternatively, an oilstone can be used.

Checking for a warped flange

Be sure to wash the carburetor thoroughly afterwards.

4. Check the condition of the throttle slide. Check for scratches or score marks on the sides of the slide. On most direct-control type carburetors the slides are chromed, so wear or scoring should not be a problem. Some carburetors use slides which are made from the same material as the carburetor body, and therefore wear is sometimes a problem. Check for corresponding wear in the throttle slide bore of the carburetor body.

5. On CV carburetors, slide condition is critical, and no imperfections of the sides of the slide can be allowed. If a rubber diaphragm is fitted on the carb slide, check it carefully for punctures or tears.

6. Check the action of the throttle slide

Working carburetor flange on emery cloth

in the carburetor body. The slide should be able to move effortlessly through the bore with no binding. If binding exists, determine the cause. Obviously, a sticking throttle slide cannot be ignored. Often a warped carburetor body will cause this. The body can be warped if the mounting nuts or bolts are overtightened. It is also recommended that throttle slide action be checked after the carburetor has been bolted to the manifold.

Conversely, the slide should not have excessive clearance in the bore. Often, such a condition will cause a clattering sound at idle. Replace either the slide or the carburetor body (or both) depending on what parts are worn.

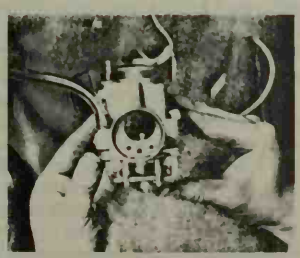
7. Clean the fuel jets in solvent and blow them clear.

CAUTION: *Never attempt to clear a blocked jet by inserting anything into its bore. Clear by blowing through with air pressure only.*

8. When installing screw-in type jets, do not overtighten them. Jets are brass and are easily damaged.

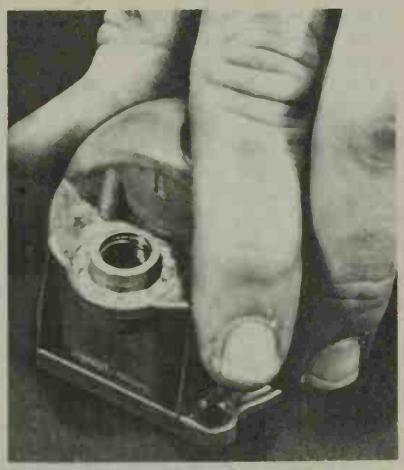
9. Inspect the needle jet and needle. The needle must be free of knicks or any signs of wear along its length. Often, these components will need to be replaced because of normal wear. As the throttle slide moves up and down while the machine is in operation, the needle rubs against the inside of the jet. Eventually, these components may wear enough to cause a noticeable rich running condition in the mid-range. If this occurs, both the needle and the jet should be replaced.

10. Make a careful inspection of the float(s). Some floats are solid, but most are hollow, being either brass or plastic. Check for leaks by shaking the float close to your ear and listening for any gas trapped inside. If semi-transparent plastic, gasoline can be detected by holding the float up to a strong light.



If the float leaks, replace it; do not attempt repairs.

On models with two connected float bulbs, check that they are level, and that the assembly is not twisted or out of alignment.



11. Check the tip of the float needle for wear or corrosion. Inspect the float needle seat as well. If there is any foreign matter on the needle or seat, remove it.

Normal (left) and worn float needle

Checking needle sealing ability

Cleaning up a float bowl mating surface

Condition of rubber o-rings is critical

NOTE: *Do not attempt to clean the needle or needle seat by lapping one against the other. This will affect the float level.*

12. On some carburetors, that is those on which the fuel feed line and the float are attached to the carburetor body rather than the float bowl, the efficiency of the float needle and needle seat can be checked as follows:

a. With the float, needle, and seat installed on the carburetor body, connect the fuel line to the carburetor;

b. Place a number of dry rags beneath the carburetor, and hold it upright (in its normal operating position) with one hand;

c. With the other hand, gently raise the float assembly until the float needle is seated. Have an assistant turn the petcock to a fuel flow position (if a diaphragm-type petcock is fitted, it must be turned to the "Prime" position);

d. If the needle and seat are in good condition, and forming a good seal, no gasoline will flow out of the carburetor;

e. If a leak is noted, replace the needle and seat.

f. The test may not be valid if the needle is pressed into its seat with more than a few ounces of pressure.

CAUTION: *While performing this test, be sure that adequate precautions are taken in the event of spillage.*

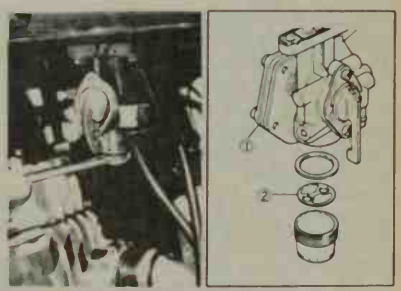
13. Check that the tapered portion of the pilot screw is smooth and clean. Replace it if it is crushed or blunted.

14. On models which use a starter-plunger, be sure the plunger is clean. If neoprene-tipped, clean it only in gasoline.

15. Clean out the float bowl thoroughly. Check for stress cracks around screw holes. If the bowl has a flat gasket surface, any imperfections on the surface can be removed by working the bowl on a piece of emery cloth or an oilstone. This, of course, cannot be done on float bowls with an o-ring or gasket groove at the mating surface.

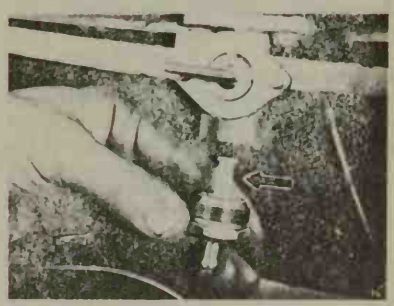
16. New gaskets, fiber washers, and O-rings should always be used when reassembling. O-rings are especially important as they may be used as air or fuel seals and even slight damage or deformation may affect the mixture.

FUEL FILTERS



Fuel filters, like air filters, require periodic maintenance.

Fuel filters are usually wire or plastic mesh which trap dirt or foreign matter in the gasoline, preventing it from clogging the carburetor jets and fuel passages.



After a time, this trapped material will impede the flow of gasoline through the system; before this happens, the filter(s) should be cleaned.

There are one or more fuel filters in the system, depending on the motorcycle involved. Prior to 1975, when Federal edict redesigned the fuel petcock, most motorcycles had a sediment bowl fitted to the petcock with a wire mesh filter just above it. After shutting off the gas, unscrew and remove the sediment bowl. Pull out the o-ring and filter screen. Wash the screen and bowl in gasoline, and reinstall.

If the petcock has no sediment bowl, the filter is probably located on the petcock intake pipe inside the gas tank. Some petcocks with sediment bowls have an additional filter here as well. Access to these filters can only

Petcock sediment bowl and filter screen

On some models, the filter is inside the tank

Petcock filter screen and o-ring

be gained by first draining all gasoline in the tank. Removal of the tank from the motorcycle first is the quickest and safest way to do this.

Petcocks are secured either with a single large nut which screws onto a fitting on the tank, or by two or more screws. In either case care must be taken on removal, since certain sealing devices are in use, such as rubber O-rings.

Clean the fuel filter(s) is gasoline and check condition. If the filter is very old, enough foreign matter may have accumulated on it to make thorough cleaning impossible. In this event, replace it.

Clogged fuel filters may cause a lean running condition at high speeds, since the engine may be using gasoline faster than it can flow through the filters. In addition, if clogged badly enough, the filters may cause hard starting, especially when the supply of fuel in the tank is low.

AIR FILTERS

Because it is designed to be replaced or cleaned at periodic intervals, the air filter is a likely source of trouble.

As it fills up with dirt, the air filter will cause the mixture to become increasingly rich. If it is not serviced, the mixture will become so rich that performance will be greatly impaired.

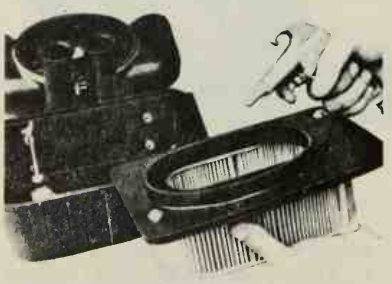
The oil-foam air cleaner is the most popular type in use today, although there are a multitude of different kinds.

The dry "paper element" air filter has been standard equipment on most motorcycles until very recently. The paper is porous, and will therefore allow air to pass more or less freely, while retaining foreign matter.

Most paper elements are pleated to afford maximum intake area in a given space.

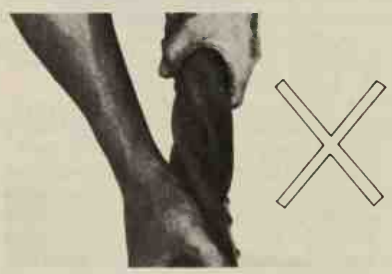
Paper elements can be serviced, after a fashion, by brushing dirt deposits off the outside and using compressed air to blow out remaining fine dirt from the inside of the filter box. This technique, however, is very limited in effect, and it makes more sense to simply replace the element after several thousand miles.

"Oil-foam" filter elements are now in wide use, and have many advantages over the paper filters they are replacing. First, the foam elements can capture much smaller bits of foreign matter, and yet are less restrictive to air. Secondly, the foam elements are easy to service and can be reused.



Foam filters depend upon an oil film for filtering effectiveness.

Service oil-foam filters by first washing thoroughly in a solvent. Let the filter soak up the solvent like a sponge. Squeeze it dry. Repeat the procedure until the solvent being squeezed off ceases carrying off dirt. Be sure to *squeeze* the element: do not wring it out, as this risks tearing it, or at least damaging the close-knit pores.



Soak the cleaned element in the type of oil recommended by the manufacturer. In most cases, standard motor oil (20W/50 or 30W) can be used, but some filters specify 80W or 90W gear lubricant.

Squeeze off the excess oil, and the filter is ready to use again.

Another kind of air filter which is coming into use today can best be described as the "wet-paper" type. At the present time, this kind of filter is not standard equipment on any popular motorcycle, but is available as an accessory item. This filter is composed of a special type of paper which offers almost no resistance to air but, when treated with a special oil supplied by the manufacturer, offers an extremely high degree of filtering. This filter must not be treated with motor oil or the like—only with the special oil. Cleaning is accomplished with lacquer thinner, and the filter is reusable.

Do not wring out foam-type air filters

Squeezing off the excess oil

Service Intervals

Air filter service intervals will depend entirely upon the environment in which the machine is ridden, although the "Periodic Maintenance" chart in each section will give a guide to service under routine conditions. This is usually about 5000 miles for road bikes, and about 2500 miles for off-road machines, but this can be far too long if there is a lot of dust in the air.

The outward appearance of the air filter element is no reliable indicator of its condition. Some oil-foam filters tend to take on a dirty appearance after only a few miles, while filtering ability is unimpaired. Some paper elements never look too bad, but may be almost fully clogged.

Fitting Accessory Filters

Non-stock or accessory air filters are a popular item, and may benefit your machine. Often, such filters claim less intake restriction as well as improve filtering properties, and, if this is true, it may be necessary to rejet the carburetor(s) to avoid a lean mixture. Generally, the manufacturer of the accessory air filter will provide this information.

The filter you choose should be made specifically for your machine, as this will help you avoid numerous troubles in adapting and mounting the new filter. Even a reputable element may cause a decrease in performance if it is incorrectly mounted or simply too small to do the job. Additionally, foam air cleaners depend on a wire mesh or a coil spring to keep their shape. If incorrectly installed, engine suction can cause them to contract at high rpm, effectively cutting down the amount of air supplied.

HOSES/CLAMPS/MANIFOLDS

Periodic inspection of the fuel lines and manifolds is an important safety item which should not be overlooked.

Take the time to check the following points:

Be sure that all fuel-carrying lines are tightly secured by safety clips or clamps at both ends.

Be sure that the lines are fitted on to their respective spigots as far as they will go.

Check that the lines are properly routed. Fuel lines must not touch the cylinder head or any other part of the engine. Be sure that the lines are long enough. Lines which are too short are subject to abrasion damage and cracking which may cause leaks.

Check fuel lines for any sort of damage or wear. Lines which are cracked, hardened, or otherwise unserviceable must be replaced at once. The lines should not be allowed to get to the point where they actually leak. Preventive maintenance will require replacement of old lines before they get to this point. The safety implications of gasoline leaking onto a hot engine are obvious.

On twins and multis, check that manifold balance tubes, where fitted, are tightly secured. The balance tubes should be subjected to the same rigorous inspection as the fuel lines themselves. On some models, balance tubes are a prime source of air leaks

which will cause erratic performance, or perhaps even engine overheating and/or piston seizure.

On models with diaphragm-type fuel petcocks, you should note that proper fuel flow depends on the condition of the vacuum line from the petcock to the manifold. Air leaks due to loose connections, cracks in the line, etc., will impede fuel flow or stop it all together.

On models with carburetor float bowl overflow tubes, be sure that the tubes are firmly secured to the carburetors and are properly routed to spill any gasoline well clear of the engine or other motorcycle parts.

Carburetor air leaks are a very serious matter since they will cause an extremely lean mixture which can and will damage the engine due to the heat generated in the combustion process.

The most common area in which air leaks occur is at the manifold.

Air leaks very often cause an extremely erratic idle which cannot be smoothed out by any degree of adjustment. Also, the mixture may vary depending on how hot the engine is. Therefore, settings which let the engine idle smoothly when it is cold will cause erratic operation as it heats up, and vice-versa.

To check for air leaks, warm the engine up to operating temperature and allow it to idle. Squirt motor oil carefully around potential areas of leakage such as the carburetor mount on the manifold or where the manifold mounts to the engine. If the idle changes, there is an air leak at that spot.

Manifold service checks will depend upon the type of mounting employed.

The most common type of carburetor mounting in use today involves fitting the carburetor spigot into a rubber sleeve. With this type of set-up, it is only necessary to ensure that the carburetor is fitted into the manifold sleeve as far as it will go, and that the carburetor clamp is properly tightened.

Also, be sure that the carburetor is perfectly vertical.

On some models, the carburetor(s) are rigidly mounted on the manifold by bolts or nuts. With fixtures of this sort, it is imperative that the sealing o-ring in the carburetor flange is in good condition. This can be checked by unbolting the carburetor and inspecting the o-ring. Replace it if it is chipped, cracked, hardened, or deformed. When installing a new o-ring, use of small quantity of grease in the carburetor groove and on the o-ring to hold it in place and provide a good air seal.

When installing the carburetor, be sure that the o-ring does not slip out of place.

When tightening the carburetor bolts or nuts, be sure to do so evenly and gradually.

Do not overtighten the nuts or bolts. Check throttle slide action while tightening these fasteners. If the slide suddenly sticks, the mounting flange may be warped. This condition must be remedied (see "Carburetor Rebuilding").

A third type of carburetor mounting consists of a clamp around the carburetor spigot which secures it to the manifold. With this type, there is usually a plastic gasket inside the carburetor. If the clamp is properly tightened, and the gasket is in good condition, there should be no trouble is obtaining a good seal.

CARBURETOR TROUBLESHOOTING

For the most part, the carburetor(s) will become a troublespot when something occurs which upsets the balance of gas and air going into the engine.

When there is an excess of gasoline in the mixture, it is said to be "rich." An excess of air, and the mixture is said to be too "lean."

If you have read the "Operational Description" above, it should be obvious that it is possible for the mixture to be "lean" or "rich" at one throttle opening, but normal at others. This is often caused by the installation of the wrong size jets, rather than a defect in the components themselves.

Like all other aspects of troubleshooting, an approach to a carburetor problem must in large measure depend on the nature and the history of the ailment.

Probably the most common carburetor malady is simple dirt which has gotten past the fuel or air filters and has clogged or even partially obstructed the various passages in the carburetor.

Again, individual cases must be taken into account. If the trouble has developed slowly over a number of miles, this could be the cause. If the unit(s) have simply stopped functioning correctly, however, there is probably another reason. The following may serve as a rough guide to determine whether the mixture is lean or rich.

Indications of a Rich Mixture

An excess of gasoline in the fuel/air mix is often indicated by one or more of the following:

a. Visible exhaust emissions without oil consumption. This refers primarily to four-strokes, since some visible smoke is characteristic of two-stroke engines. These emissions will be black, as opposed to the blue-white color of burning oil.

b. Spark plug(s) black or carbon-fouled. When checking the plugs for mixture, the color of the side electrode is the key. The center electrode is more of a guide to plug heat range. If the plugs are too cold, however, it may seem that the fuel mixture is too rich.

c. Engine runs better when the air cleaner is removed. Since air filters are somewhat restrictive, removal will allow somewhat more air to enter the carburetor at any given throttle opening resulting in a slightly leaner mixture. This is only a check for a rich mixture, and should not be considered a solution.

d. Engine runs worse when hot. Since engines need a slightly rich mixture when they are cold, a faulty fuel/air mix may go unnoticed until the engine is at operating temperature.

e. Performance is sluggish.

f. Engine misfires at high rpm.

g. Excessive fuel consumption.

Indications of a Lean Mixture

a. Engine is hard to start when cold, or requires excessive choking.

b. Engine refuses to idle smoothly, or rpm fluctuates at steady throttle openings.

c. Engine runs hot.

d. Spark plugs are white or yellow in color. In extreme instances, the side electrode may be eroded or partially melted, both electrodes showing rounded edges.

e. Engine runs better when the choke is engaged.

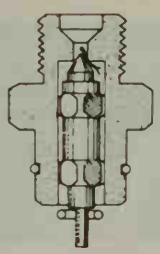
f. Engine runs better at slightly less than full throttle than it does when wide open.

g. Engine runs worse when the air cleaner is removed.

In addition to determining whether the mixture is rich or lean, you should also analyze whether the imbalance occurs at all throttle openings, or just one in particular. If the malady seems to occur at one spot, it is probable that the trouble lies with the metering components which control that particular range of operation. For example, an overly rich mixture in the mid-range may be due to a worn needle and needle jet.

Carburetor Flooding

Flooding of the carburetor will cause an overly-rich mixture at all throttle openings if not too severe, or leakage of fuel from the float bowl if it is really bad.



Minor flooding, which may not be immediately recognizable as such, can be caused by an incorrect float level. Another cause can be a worn float needle. Checking and adjusting the float level varies from carburetor to carburetor and procedures and specifications should be obtained from the model sections. As a rule, two-strokes are somewhat more sensitive to float level than are four-strokes.

Major flooding of the carburetor(s) is usually indicated by the discharge of gasoline. Most carburetors are equipped with float bowl overflow tubes, and if fuel is being discharged from here after the machine has been sitting for a few minutes with the petcock open, there is undoubtedly something amiss with the float assembly.

On models which do not have overflow tubes, removal of the air cleaner hose may give an indication of excess fuel in the float bowl. If raw gasoline appears at their air passages in the carburetor mouth, either the float level is far too high, or the float needle and seat are not forming an effective seal.

The most common float malady is caused by the failure of the float needle to form an effective seal with its seat. The float bowl then becomes overfilled with gasoline. Often, a routine cleaning of the float needle and seat is all that is required, assuming that the needle is being held off the seat by a transient bit of foreign matter.

On older machines, however, this problem can be caused by corrosion built up on the needle or the seat. If this is the case, both components should be replaced. The needle

Float needle seat blocked by foreign matter

seat on most carburetors can be unscrewed for replacement. Never attempt to reform a seal by lapping the needle against the seat. This will cause wear on one or the other, and will change the float level. Needle seats are almost always brass, and therefore highly resistant to corrosion. Long periods of disuse, however, can caused the build-up of foreign matter which is almost irremovable. Float needles can be brass or plastic, or neoprene-tipped. Any foreign matter on the tip of the needle can be removed with solvents (on neoprene needles only gasoline should be used to clean the tip) and compressed air, but no attempt should be made to scrape the tip clean.

High-mileage machines may show wear of the needle tip. However, wear must be severe to be easily noticeable, and can be present though scarcely visible. If flooding is a problem, replacement of the needle is advisable.

On carburetors on which the float assembly is mounted on the carburetor body and the fuel feed is on the body as well, the efficacy of the float needle and seat can be checked as follows:

Remove the float bowl. Place a suitable container beneath the carburetor to catch any gasoline which may spill.

Carefully raise the float bulbs with your finger until the needle is gently seated. Do not use excessive pressure.

Turn on the fuel. No leakage should be apparent. If fuel leaks from the needle seat, replace or clean the needle and seat. When the needle is seated, fuel flow must be entirely cut off.

A less common cause of flooding, but one which should be checked, is failure of the float bulbs. If gasoline leaks into the bulbs, they will allow float level to become higher. Eventually, enough gasoline may leak in to "sink" the bulbs, at which time the needle will remain open at all times.

It is easy enough to check for a defective float: just shake it next to your ear and listen for trapped gasoline. Alternatively, semi-transparent plastic floats can be held up to a strong light and any gasoline inside will become visible.

Punctured or leaking floats must always be replaced. No repairs are possible.

Troubles of this sort have been largely sorted out by modern carburetors, many of which use solid buoyant float bulbs of plastic or resin as distinguished from older floats of brass or hollow plastic.

Effect of Altitude on Carburetion

Increased altitude tends to produce a rich mixture; the greater the altitude, the smaller the main jet required. Most standard jetting is suitable for use in altitudes up to approximately 3,000 feet. If you use your machine constantly in altitudes between 3,000 and 6,000 feet, the main jet size should be reduced about 5 percent. A further reduction of 4 percent should be made for every 3,000 feet in excess of 6,000 feet altitude. No adjustment can be made to compensate for the loss of power due to rarefied air.

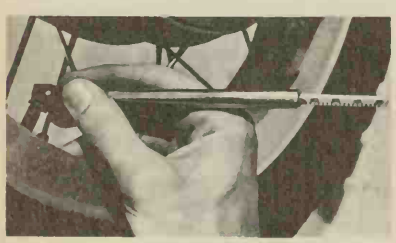
CHASSIS

TIRES

Checking Pressure

1. Tire pressures are recommended by the manufacturer and you should abide by the recommended pressure unless the motorcycle is being put to some special use, such as competition.

These pressures are determined by considering the design of the motorcycle, tire sizes, the weight of an average rider, and several other factors. The resultant pressure should give a comfortable ride, reasonable tire life, and, most importantly, safe handling. It is therefore not wise to deviate from the recommended pressures unless you really know what you are doing.



2. On most late-model motorcycles, the tire pressure is given somewhere on the motorcycle. If it isn't here, check the "Maintenance Data" chart of the applicable section.

You will note that pressure may be different for the front and rear wheels. Also, pressure variations may be necessary if you carry luggage, ride two-up, or will ride at high speeds for extended intervals (no longer very wise). In general, you might add 4–6 psi to the rear wheel and 2–3 psi to the front over normal pressure to compensate for these conditions.

3. Tire pressure should be checked every two weeks or so. A hand-held gauge is recommended, since it is a fact that the pressure meters on the air hoses found in service stations are not particularly accurate in many instances.

Check pressures when the tires are *cold*. Tire pressure will build up as you ride. The tire gets hot, and the air inside tries to expand. A ride of a mile or so probably will not affect pressure significantly, however, so you can ride to the local gas station before checking the tires.

4. Overinflated tires will wear rapidly, give a harsh ride, and may decrease braking ability. Underinflated tires may cause "squirrely" handling.

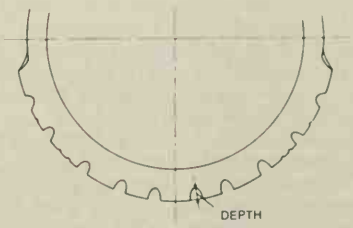
Checking tire pressure

Tire Inspection

1. Tire tread depth is one of the most critical items you can check. Since many states have their own laws in this regard however, it is not possible to generalize with a great degree of accuracy as to what depth constitutes the "safe" limit. The following is provided only as a rough guide based on a survey of various manufacturers' recommendations:

For road machines: 1.5 mm (0.06 in.) front
2.0 mm (0.08 in.) rear

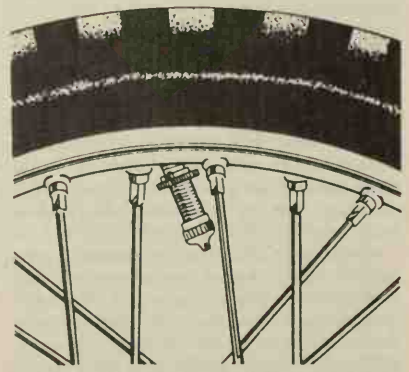
For light-weight off-road bikes: 1.0 mm (0.04 in.)



For Superbike-class machines used at high speeds: 2.0 mm (0.08 in.) front
3.0 mm (0.12 in.) rear

This measurement is taken at the center of the tire tread, and at the point of minimum depth if the tire is unevenly worn.

2. Occasionally spin each tire and remove any pebbles, nails, etc., which may have become stuck in the tread grooves.



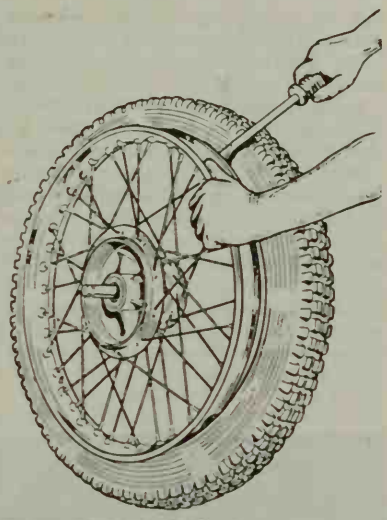
3. Check for uneven or unusual tire wear or feathering of the tread. Any number of things may cause uneven tire wear: a misaligned wheel due to clumsy rear chain adjustment or bent forks; a rim out of true; an unbalanced wheel; or worn or damaged bearings.

4. Occasionally, loosen the valve stem locknut. If the valve stem tilts to one side when this is done, it indicates that the tire has slipped around the rim during use.

Tire tread depth

This condition must be corrected, or the tire may slip enough to pull the stem out of the inner tube causing a blow-out. Deflate the tire and move it back so that the stem protrudes at right angles to the rim. If a rim lock is fitted, do not forget to loosen this first and push it off the tire bead. If it isn't possible to move the tire by hand, you should remove the wheel and break the tire off the rim by walking around on the sidewall.

If the valve stem tilts to one side when the locknut is loosened, the tire has slipped around the rim

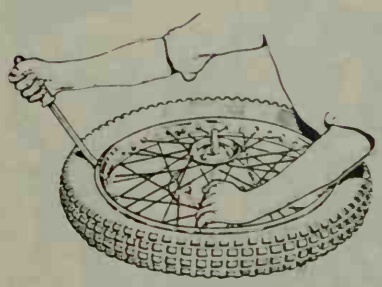


Tire Changing

To change a tire you will need two motorcycle tire irons, a lubricant such as soapy water or dishwashing liquid, and a plastic mallet which, while not entirely necessary, is certainly helpful.

You can purchase suitable tire irons at any motorcycle shop, or it is possible that they may have been included in your bike's toolkit. Tire irons are specifically designed for the job. They are angled to provide good leverage and have smooth, rounded spoons to prevent pinching the tube. Although some irons may seem small, if you are using the right method they should provide sufficient leverage to get the tire off the rim. There is no acceptable substitute for good tire irons. Attempting to use screwdrivers or other levers for this job is only asking for trouble.

If you have cast alloy wheels, tire irons should be used with care to avoid damaging the wheel. The same is true to a lesser extent with alloy spoked rims which can be scratched. It may be possible to cover the shaft of the irons with a piece of an old inner tube or the like to obviate the chances of damage.



A large sheet of cardboard can also decrease chances of damage to the wheel or brake disc (if fitted). Changing the tire on a concrete surface can easily chip chrome or scratch the rim or brake disc, while changing it on the lawn will certainly get dirt or grass into the wheel bearings unless a rag is placed under the hub.

Removing the tire from the rim

Mark the location of the valve stem before removing the tire

Prying off the first bead

1. After removing the wheel from the motorcycle, take out the valve core. Remove the valve stem nut(s). If a rimlock is fitted, remove its nut and push the rimlock down off the tire bead. If the same tire is to be refitted, mark the location of the valve stem and the direction of rotation on the tire sidewall.

2. Place the wheel on the ground and walk around the tire to break the bead off the rim. This may be necessary if the tire has been on the rim for some time.

3. Smear some soapy water or dishwashing liquid around the beads on both sides of the tire.

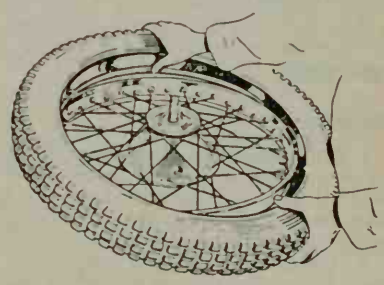
4. Beginning at the valve stem, use the tire irons to lever one bead off the rim. The tire bead opposite the valve stem should be pressed well down into the rim well. Kneel on the tire, if necessary to hold the bead down. Start by inserting both tire irons under the bead a few inches apart. Do not insert them too deeply or you may catch the tube. Pull back on both irons simultaneously until a portion of the bead is over the rim. Then remove one of the irons and use it again several inches away from its first position. Continue around the tire until one side is completely free of the rim.

5. Pull out the tube. If the tire is to be replaced, remove the rimlock and lever the remaining bead off the rim.

6. Check the tube for leaks. Patching the tube is not recommended except in emergency situations. The patch may leak or may upset tire balance. Get a new tube if a puncture is evident.

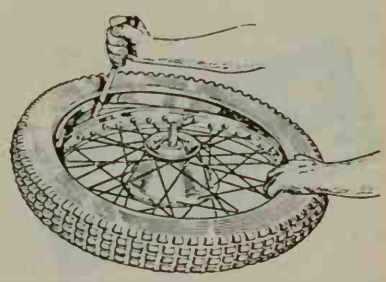
7. Carefully remove the rim band and, using a wire brush, remove any rust deposits here with the wire brush.

8. Check the spokes for looseness and tighten if necessary. If this is done, check that no spoke end protrudes from its nipple. Grind down any protruding spoke ends to obviate the chances of a puncture. Carefully refit the rim band so that it covers all the nipples.

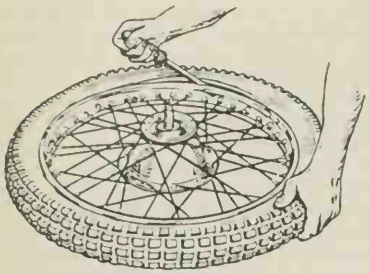


9. The tire must be mounted so that the mark on the sidewall aligns with the valve stem. New tires will have this alignment mark painted near the bead. Also note direction of rotation, if applicable. On some tires the direction of rotation will be different depending on whether the tire is mounted on the front or the rear of the motorcycle. If a rimlock is fitted, be sure to install it before the tube, but do not fit its locknut.

10. If you have only replaced the tube, and the tire is still on the rim, care must be exercised when stuffing the tube into the tire since it is possible to twist it. If the tire has been completely removed, the easiest method is to mount tire and tube together. Install the valve core into the stem and put just a few lbs of air in the tube. You should inflate the tube just enough so that it holds its shape, but not so much that the tube expands. Place the inflated tube into the tire. Approximately aligning the valve stem and the hole in the rim, lever tire and tube together over the rim. Be sure to lubricate the tire beads as on removal.



11. If it is very difficult to lever the tire bead on, use a plastic mallet to strike the bead, thus forcing it over the edge of the rim as you move around the tire with the tire irons.



Note the direction of rotation marked on the sidewall

Levering on the first bead

Levering on the second bead

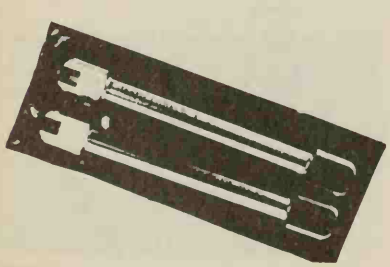
Check that the alignment mark is equidistant from the rim all the way around

12. After the tire and tube are installed, temporarily overinflate the tube to seat the tire. The tire will have an aligning mark which is a thin line molded into the sidewall and which will appear just above the edge of the rim. This line should be equidistant from the rim edge all the way around the tire. If it is not concentric, the tire is not properly seated. This is sometimes caused by rust on the rim and can often be remedied by thoroughly lubricating the beads and temporarily overinflating the tube.

13. After the tube has been inflated to the correct pressure, tighten the valve stem locknut(s) and the nut on the rimlock if one is fitted.

14. The wheel should be balanced after completing this operation.

WHEELS



Spokes

1. Spokes should be checked periodically for proper tension. Spin the wheel slowly while striking each spoke lightly with a screwdriver. Each one should emit a "ping" of approximately the same pitch.

2. A loose spoke will emit a dull sound. Such spokes should be tightened. The nipple, however, should not be turned more than two revolutions. To exceed this risks puncturing the tube with the end of the spoke. If two turns will not tighten the spoke, remove the tire and tube before continuing.

Spoke nipples should be turned only with a genuine spoke nipple wrench which you should be able to purchase from your dealer.

3. If more than two adjacent spokes are found to be loose, the rim should be checked for rim-out, and trued if necessary. On-bike tightening of loose spokes is intended only to secure spokes which may have loosened from vibration or setting. It is not intended to true up rims which have been knocked out of kilter. Continuous loosening of spokes should be remedied by removing the wheel and having it properly trued.

Each spoke should emit a "ping" of about the same pitch

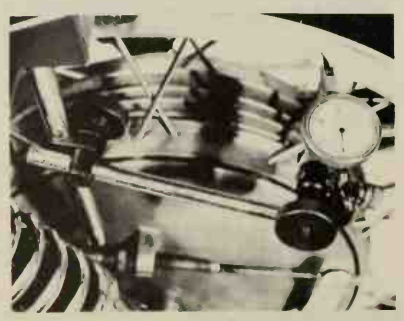
Securing a spoke with the special wrench

Wheel Balancing

Wheels should be balanced each time the tire is removed or replaced. A badly balanced tire may make itself evident by vibration (especially if the front tire is out-of-balance) or by unusual tire wear.

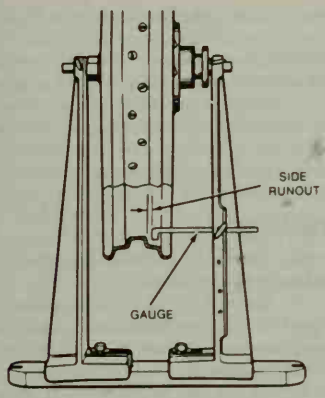
1. Wheels should be balanced on a wheel stand. Balancing on the machine is not recommended due to drag imposed by chains, brake pads, and even wheel bearing grease seals. If a stand is not available, it is permissible to hang the wheel by the axle between two benches or chairs. Only make sure that both surfaces are of equal height. To obtain the most accurate balance it is necessary to remove as much rotation friction as possible. On some designs, wheel bearing grease seals contribute to friction, and really should be removed if possible. It may also be helpful to oil the axle as the wheel is turned. If the wheel will not rotate freely, determine the cause (i.e. bad bearings) before balancing.

Installing a balance weight



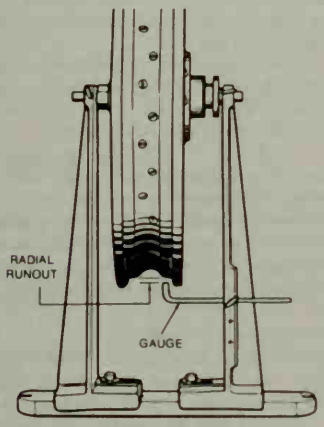
2. The tire and tube must be in place and properly installed during balancing. If the wheel has a disc brake, leave it in place. Drum brake hubs should be removed.

3. If there are tire balancing weights already on the spokes, leave them there. Remove or reposition these weights once you are into the procedure.



4. Spin the wheel slowly several times in succession, marking the tire with a grease pencil or the like at the lowest part of the wheel each time it stops. If the same mark rotates to the lowest position several times in succession, this is the heaviest part of the assembly. Ideally, the wheel would stop rotating at random locations. If a heavy point is noted, attach a tire balance weight to a spoke directly opposite the heavy point. Repeat the procedure, adding or repositioning weights so that the wheel will not stop at any one point in particular when it is spun.

5. Balance weights are available in several forms, the most popular being the type which fits over the spoke nipple and is secured with pliers. Another kind is an almost-flat piece of lead which attaches to steel rims by means of adhesive. Cast alloy wheels may require special kinds of balance weights. On this kind of wheel, always install the balance weight on the outer part of the rim, not on the sides of the spokes.



Balance weights may be available in dif-

ferent weights. Use the lightest ones to start. If you have to add more than three or four weights to correct balance, there is probably something amiss.

As an alternative to balance weights, there are several brands of balancing *fluid* currently on the market. This is added to the tube and automatically balances the tire when the machine is ridden. It will also change as changes are made to the system, so that fitting a new tire will bring about an automatic compensation on the part of the fluid.

Rim Run-Out

1. Rim run-out can be checked with a dial gauge or a simple pointer. This check can be made with the wheels on the motorcycle. Before this is done, however, be sure that the wheel bearings are in good condition (see "Wheel Bearings"). Misleading results may be obtained. All spokes must be secure.

2. Rims should be checked for lateral (side-to-side) run-out, and for concentricity (up-and-down movement). In both cases, the maximum acceptable variance is 2.0 mm (0.08 in.). If either lateral or vertical run-out exceeds this amount, the rim should be trued. To true a rim, the tire and tube must be removed, and a wheel stand should be used.

3. It is not possible to true rims which are bent, even if the damage is slight, since the spokes cannot exert enough force to bend the rim back into shape. Such rims must be replaced.

4. If the rim shows both lateral and vertical run-out, the vertical run-out should be corrected first. This can be done by first loosening those spokes opposite the high-spot, and then tightening the spokes at the high-spot. Spokes should be loosened or tightened in small, even increments since lateral run-out will be affected while correcting vertical run-out.

5. If a new rim is being fitted, it is necessary to have the rim at least approximately centered on the hub before attempting to true it. This can be accomplished in most cases by tightening the spoke nipples by approximately the same amount: that is, so that about the same number of spoke threads show at each nipple. File off the ends of any protruding spokes.

6. The fitting of a new rim can be facilitated by securing each set of two spokes loosely with lengths of wire or tape before removing the old rim.

Wheel Bearings

Most motorcycle wheels are fitted with ball bearings, although a few use roller or tapered roller bearings.

Each wheel has two bearings which in most cases are press-fit into the hub and are separated by a spacer tube. Some wheels use threaded retainers or perhaps circlips to secure one or both bearings. Grease seals are usually fitted to both sides of the hub to keep the bearing grease in and dirt and moisture out.

Some larger bikes also have a "wheel bearing" in the rear wheel sprocket assembly for added rigidity.

Wheel bearings can usually be inspected on the bike simply by grasping either side of the tire and checking for play. There should be none.

If play is evident, the bearings may be worn and replacement will be in order. Bearings are always replaced in pairs.

Checking wheel bearings for play

REMOVAL AND INSTALLATION.

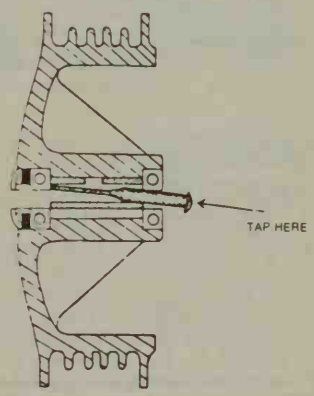
Removal of the bearings is obviously necessary for replacement and also for repacking which should be carried out in accordance with the periodic maintenance schedule for your motorcycle.

You should note that the removal process frequently ruins bearings because they are press-fit in the hub and must be driven out. This is especially true on high-mileage machines. In addition, grease seals should always be replaced with new ones if removed.

1. Remove the wheel from the motorcycle.

2. Remove any dust covers, spacers, etc. from either side of the hub.

3. Pry out the grease seals, if accessible. Machines with tapered-roller bearings use the seals to hold the bearings, and once the seals are removed, the bearings will come out.



Prying out a grease seal

4. Remove any retainers or circlips from the hub. Note that some threaded retainers are *left-hand thread*.

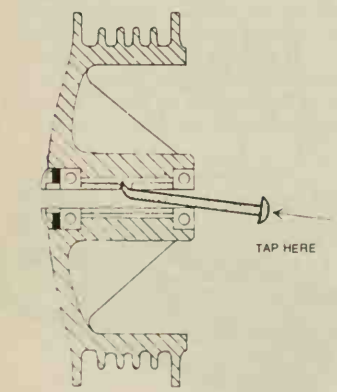
5. Wheel bearings are driven out with a drift in most cases. It is sometimes helpful to heat the hub very gently to facilitate removal. Heating the hub with a rag soaked in boiling water is one way to do this. Some manufactures specify that the hub should not be heated to more than 212° F (100° C).

6. The best way to remove wheel bearings is to tap around the *outer* race with a punch and hammer. This is not possible in most cases, however. If the axle is suitable, it can be inserted into the bearings. A sharp

Removing a wheel bearing

Wheel bearing removal

blow on one side of the axle may then be used to dislodge the bearing on the opposite side. It is possible that the bearing will not even look like it moved, but check anyway. In some instances a slight movement is all that is necessary, and the bearings will be free.



If this is not possible, the bearing can be removed by reaching through the hub with a long punch. Try to move the spacer tube to one side so that ample purchase can be obtained. Tap the bearing out evenly, alternating your blows around the circumference of the race.

Yamaha motorcycles are equipped with a hole in the spacer tube which allows the bearing to be removed without striking the bearing directly. If a properly hardened hooked tool is available, it can be used as illustrated to remove the bearings.

7. Once one bearing is removed, you can take out the spacer tube. If this is only a routine repacking, leave the other bearing in place if possible. As noted, removal risks ruining the bearings, and repacking is possible with one removed.

8. Remove old grease from the hub and the bearings with a solvent. After the bearing is clean, lubricate it with oil and check for smooth rotation. Any roughness, binding or clicking sounds which appear indicate that both bearings should be replaced. Place each bearing on a flat surface and hold the outer race firmly in place. Attempt to move the inner race back and forth. Little or no movement should be noted, or a worn bearing is indicated.

9. Repack bearings with a good grade of wheel bearing grease of the type recommended for your motorcycle. Grease should be pressed into the bearing until it is full. Place a quantity of grease into the hub as well.

Play or movement of the inner race indicates a worn bearing

Packing a wheel bearing

10. Bearings should be installed by tapping them into place. Drive the bearing in squarely and evenly. Do not allow the bearing to become cocked while entering the hub. Tap on the *outer* bearing race only.

Bearings which have one side sealed are always installed with the sealed side facing *out*.

If a retainer or circlip is fitted to one side of the hub, the bearing on that side should be installed first. After the bearing is installed, fit the retainer or circlip. This will ensure proper location of the bearing to ease fitting the other one.

11. Install new grease seals.

DISC BRAKES

Bleeding

A mushy feeling at the brake lever or pedal is most often due to air in the lines. This can happen if the fluid level drops too low, or if any line or hose is disconnected for any reason. This requires bleeding of the brake to remove the air.

NOTE: *Sometimes the bleeding procedure is easier if the motorcycle is allowed to sit for several hours without operating the brakes. This allows the tiny air bubbles to concentrate into fewer large ones which may be bled off more quickly and thoroughly.*

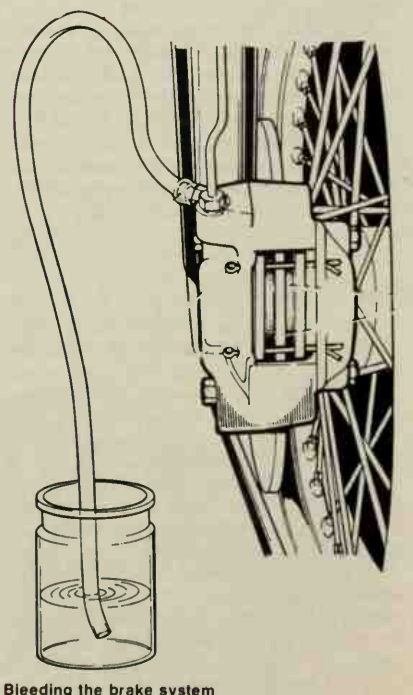
PRECAUTIONS

Certain precautions should be taken when working with disc brake fluid.

a. Brake fluid absorbs moisture very quickly, and then becomes useless. Therefore, never use fluid from an old or unsealed container.

b. Do not mix brake fluids of different types. If the fluid in the system is the original factory fluid, it may be incompatible with what you can purchase. In this case, the entire system should be flushed and refilled with the new fluid.

c. DOT #3 or #4 hydraulic disc brake fluid is recommended for almost all motorcycles at this time. However, you should check the applicable model section.



d. Brake fluid will quickly remove paint. Avoid damage to the gas tank by placing a protective cover over it.

To bleed the brake system, obtain a length of transparent plastic hose, the inside diameter of which is such that the hose will fit tightly over the bleed nipple of the brake caliper.

Also needed is a small cup.

Fit the plastic hose to the bleed nipple, and put the other end in the cup which should have an inch or so of new brake fluid in it. Be sure that the end of the hose is below the surface of the fluid in the cup.

The hose should not have any sharp bends or kinks in it. It should loop up from the bleed nipple, and then down towards the cup.

Bleeding the brake system

The motorcycle should be on the center stand with the forks centered.

Remove the master cylinder cap and diaphragm and check that the fluid level is topped up to the indicated line.

Apply the brake lever slowly several times, then hold it on.

While holding the brake lever on, loosen the caliper bleed nipple. The brake lever will be pulled towards the handgrip (or if a rear brake, will bottom out), and fluid will be forced through the plastic hose. Try to tighten the bleed nipple before the lever bottoms out.

Note the brake fluid being forced out of the plastic hose. If there was air in the lines, air bubbles will be noted coming out of the hose.

Pump up the lever again, and loosen the nipple as before, once again checking the fluid being forced out. When air bubbles no longer issue from the plastic hose, the system is bled.

Be sure that the master cylinder reservoir is kept topped up during the bleeding procedure.

Flushing

The procedure for flushing a brake system is identical to that for bleeding, except that the process should be continued until new brake fluid begins to issue from the plastic hose. You will begin by pumping out the old fluid with the lever while adding the new fluid in its place. After the new fluid starts coming out, begin checking for air bubbles as outlined above.

Installing Brake Pads

This procedure will vary according to the make and model of the motorcycle, but all have certain points in common.

a. When new pads are fitted, avoid hard braking if possible for at least 50 miles to give the new pads a chance to seat themselves.

b. Brake fluid and solvents must be kept off the brake pads. Some manufacturers recommend that the back and sides of the pad(s) be lubricated with special PBC grease. If this is necessary for your motorcycle, it should be available from your dealer.

DRUM BRAKES

Checking for Wear

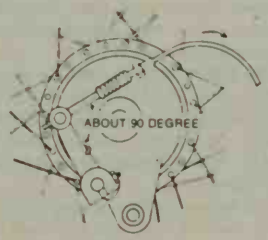
1. Late model drum brakes have wear indicators fitted to the brake cam. In most cases these consist of arrows. If the arrows align when the brake is applied, the brake linings are worn to the point of replacement.

2. Brakes not fitted with indicators can be checked with the wheel in place. When the brake is applied, the angle formed by the brake rod or cable and the brake lever should not exceed 90°. After this point, braking effectiveness will be reduced.

3. On brakes without wear indicators, an occasional check of lining thickness is recommended. Minimum allowable lining thickness is usually given by the manufacturer, and may be given in your state's motor vehicle code. It is approximately 0.08 in. (2.0 mm) measured at the lining's thinnest point, but this value is only a generalization, and the exact figure must be obtained from your owner's handbook or shop manual, as it differs from bike to bike.

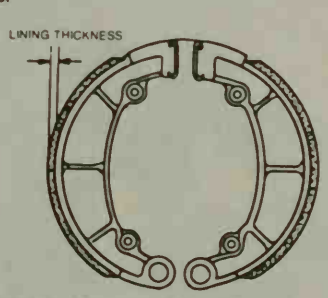
On machines with riveted brake shoes, the thickness of the lining must be measured from the top of the rivets. On bonded shoes, it is measured from the surface of the shoe casting.

Brake Service



The following procedure is to be considered a general guide to inspecting and servicing a drum brake assembly. The procedure may vary in detail depending upon the design of the brake assembly in question.

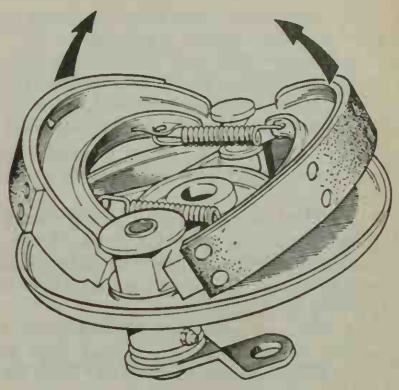
1. Remove the wheel from the motorcycle and separate the hub from the brake plate assembly.



2. Wear of brake linings can be checked with the linings in place. Be sure to measure brake lining thickness at the linings' thinnest points. On riveted brakes, measure the distance from the top of the rivets to the lining surface.

3. Check the linings for grooves, scoring, or other signs of unusual wear. Most damage of this sort is caused by particles of dirt, which have entered the brake drum. If badly scored, the shoes must be replaced. If the shoes are scored, the drum should be checked for the same type of damage.

Be sure that there is no oil or grease present in the linings. Oil-impregnated linings must be replaced. If the linings show this condition, determine the source of the lubricant: defective wheel bearing grease seals, excessive chain lube, etc.

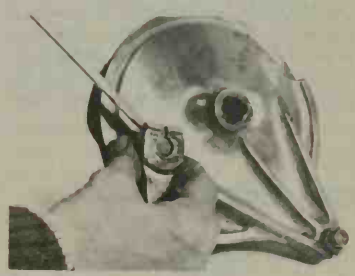


The angle between the brake rod or cable and brake lever should not exceed 90° when the brake is applied. If it does, check the linings for wear

Check lining thickness with a caliper

Removing the glaze from brake linings

Prying linings off the brake plate



4. If the linings are usable, rough up their surface with sandpaper. Then clean them with alcohol or lacquer thinner. Polish the brake drum surface removing any rust or dirt and clean the drum thoroughly.

5. To disassemble the brake plate, remove the shoes. On some models, this is possible simply by grasping both shoes and folding them towards the center of the brake plate. Other models, however, are fitted with retainers or guards. Remove any cotter pins and washers from the brake cam(s), then remove the shoes.

NOTE: *The plurals refer to the twin-leading shoe brakes.*

6. To remove the cam(s) from the brake plate, remove the brake lever pinch bolt(s). Most brake levers are fitted on splines and will have to be pried off carefully. After the lever is removed, the brake cam can be tapped or pushed out of the brake plate. Note any dust seals or washers on the brake cam.

7. Check that the brake lever pinchbolts are not bent. This can easily happen if they are overtightened. Replace any bolts in this condition. Inspect the brake lever splines and replace the lever(s) if these are worn or stripped.

Removing the brake lever

8. Inspect the splines on the brake cam(s). These should be in good condition. Check that the brake cam(s) are not bent and that they can rotate freely in the brake plate passage. If it will not, use a fine grade of sandpaper on the camshafts and the surface of the brake plate passage.

9. Clean the cam(s) thoroughly in a solvent to remove any old grease, rust, or corrosion. Use sandpaper or emery cloth to polish the cams. Clean off any residue; before reassembly, smear the cams with chassis grease.

10. Inspect the brake plate for cracks or fractures, and replace it if necessary.

11. On twin-leading shoe brakes, the brake plate linkage should be checked. The connecting rod is secured to each brake lever by a clevis pin and cotter pin or clip. They should be checked for wear, especially on high mileage machines, and replaced if necessary.

12. Check the condition of the brake springs, noting any twisted or fatigued hooks. Replace any broken, rusted, or old springs with new ones. Check spring free length if specified for your bike.

13. Clean all metal parts thoroughly with a suitable solvent, making a special effort to remove the dust and built-up dirt from the backing plate.

14. When reassembling the brake plate, note the following points:

a. Ensure that the brake cams are lubricated with chassis grease;

b. The use of new dust seals is recommended;

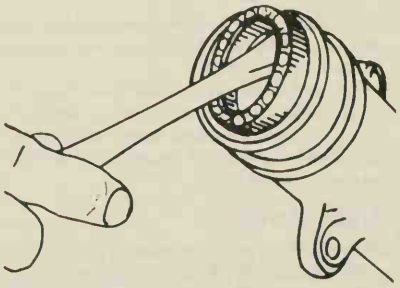
c. Lubricate the brake shoe pivot points with a little grease;

d. Install the shoes as on removal. Hook them together with the springs, and fold them down over the brake cam(s) and pivot(s). Install new cotter pins to the pivot points;

e. When installing the brake lever on the brake cam, be sure that the punch marks on the lever and cam align, if applicable.

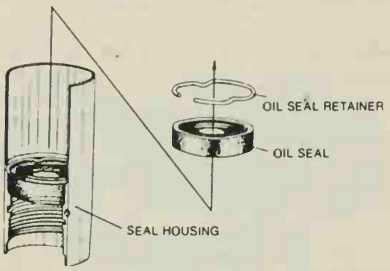
15. The drum should be checked for concentricity. An out-of-bound condition is usually noticeable as an on-off-on feeling when the brake is applied while riding. With the wheel assembly mounted on the machine, spin the wheel while applying the brake very lightly. The rubbing noise of the brakes against the drum should be heard for the entire revolution of the wheel.

16. An out-of-round condition and most scoring can be removed by having the drum turned on a lathe. This operation should be entrusted to a qualified specialist with the proper equipment. Usually, the tire and wheel bearings will have to be removed so that the wheel can be checked to the lathe. If the rim needs to be trued, have this done before any work on the drum is performed, as the action of the spokes while truing the rim may further aggravate the drum warpage.



FRONT FORKS

Seal Replacement



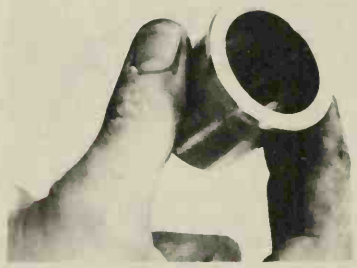
1. Fork slider oil seals may simply wear out over a period of time and then begin to leak. Some causes of *rapid* wear of the seal lips include damage during installation, dirty, contaminated fork oil, damaged dust seals or fork gaiters, rust, corrosion, or scratches on the fork tube, a bent fork tube, or rubber-damaging oil in the forks.

Seals may also leak if the forks are overfilled.

2. On most motorcycles, the seals can be replaced simply by removing the fork sliders. It is necessary to remove the front wheel, fender, brake caliper (if applicable), etc. Refer to a shop manual for removal procedures. These will of course vary depending on the make and model of the machine.

Prying out a front fork oil seal

Typical slider oil seal mounting



3. The slider seals are pressed into the top of the fork slider on most bikes, although on a few, the seals may be in the circular nut threaded onto the top of the slider.

Seals must be pried out with a suitable lever. Seals should always be replaced once the slider is removed from the fork tube. Condition of the seals cannot be determined from examination of the lips.

When prying out the seals, be sure to protect the upper lip of the fork slider. This can be accomplished by placing a soft metal pad beneath your lever. Also take care that the end of the lever does not score the inner wall of the slider.

Install new seals by pressing them straight into the slider. Often, one of the old seals can be used, placing it on top of the new seal and tapping around the edges to force the new seal into place. Alternately, a suitably sized socket can be placed over the seal to use as a drift.

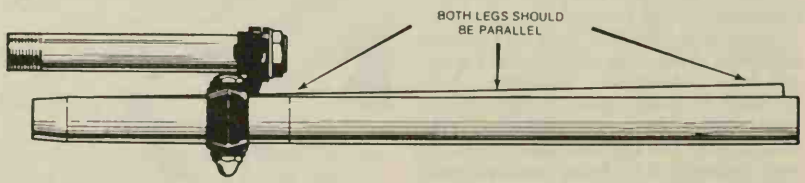
4. Always coat the lips of seals with the type of oil you are going to put in the forks.

Check slider bushings for scoring or wear

Component Inspection

1. As previously noted, fork disassembly procedures vary from model to model. There are, however, two popular methods of holding the forks together, and these are by means of a large circular nut at the top of the slider, and by means of a bolt at the bottom of the slider which will be accessible after removing the axle. Some forks have both.

2. Drain fork oil before disassembly is attempted. Be sure the motorcycle is firmly supported with the front wheel off the ground.



3. Some forks require special tools for disassembly. On models with a bolt under the slider, you should note that often this bolt is threaded into the fork damper, which may turn with the bolt when you attempt to remove it. A special tool is used, inserted through the top of the fork, to hold the damper while the slider bolt is removed. It is often possible to work around this tool by leaving the filler cap and inner fork spring in place, the spring tension being used to hold the damper.

4. Forks with sliders secured by circular nuts may be somewhat easier to disassemble. The slider must be secured when attempting to remove the nut, and this can be accomplished by inserting the axle through the fork legs. Removal of the nut itself is done with a special strap wrench or pin wrench in most cases. It is possible to remove the nut by wrapping a piece of inner tube around the nut, securing a large heater-hose clamp over it, and using a vise-grip pliers on the clamp screw to turn off the nut.

5. In the event that the fork tubes are to be removed from the triple clamps, be sure that all applicable pinchbolts are loosened. If the fork tubes are stuck, try spreading the lower triple clamp slot with a wedge, if such a slot is provided. Alternately, install the filler cap, turning it in several turns, then strike it sharply with a plastic mallet. This should serve to free the tube. This treatment should not be carried to extremes, however, since it is possible to crush the filler cap threads.

6. Fork tubes should be checked for condition. If chromed, all plating in the area on which the slider or slider oil seals ride must be in good condition. If the plating is scratched, flaking, or worn, the tube must be replaced.

On fork tubes which are not plated, check for rust or corrosion on the surface of the tubes on which the slider seals ride. Any roughness or build-up must be removed with a low-abrasive method. Pitting or extreme

Check for bent fork legs

rust would necessitate replacement of the fork tubes.

7. Check the fork tubes for a bent condition. Minor bends may not be visible to the eye, and run-out should be checked with a dial gauge. If a tube is only slightly bent, it may be possible to return it to its original condition with a large press, but it is usually necessary to replace tubes which are bent.

8. Check the fork springs for a compressed condition by comparing their measured free length with the standard free length if given in the specifications.

9. Check the condition of the fork slider and its fit on the fork tubes. Some forks use a replaceable bronze slider bushing. Check this bushing for scoring or wear on the inner surface. Check its fit on the fork tube. The bushing should move freely, but any wobbling or play from side-to-side would indicate that replacement is necessary.

10. Clean all damper components, blowing clear any oil passages.

REAR SHOCK ABSORBERS

Almost all production motorcycle rear shock absorbers are sealed, and cannot be disassembled. In fact, on some models, it is dangerous to attempt to do so.

If the shock leaks oil, looses its damping ability, is damaged through collision or extreme use, both units should be replaced. The springs, however, should have an unlimited life.

To check a shock absorber, remove it from the motorcycle, and compress the spring so that the spring keepers or collars can be removed. Take off the spring and dust cover, if fitted.

Push the damper rod into the damper body and pull it out. There should be considerable resistance when attempting to pull out the rod. If movement is easy, or if the two shocks show different characteristics, both should be replaced.

SWING ARM

Except on shaft-drive motorcycle, swing arms are very simple components and usually free of trouble.

Swing arms are usually attached to the frame by means of a heavy shaft which may ride in bushings or needle bearings. Wear to these bushings is the prime trouble spot of the swing arm.

To check your swing arm, proceed as follows:

a. Remove the rear wheel, shock absorbers, and chain guard.

b. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced.

c. Check that the rear wheel mounting plates are parallel.

d. Grasp the legs of the swing arm and attempt to move it from side-to-side. Any noticeable side-play will indicate that the swing arm bushings need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

Bushings are usually press-fit in swing arms, and, if worn, they should be driven out and replaced with new ones. Do not remove pressed-in bushings unless you intend to replace them, since they will be ruined by the removal process.

When disassembling a swing arm bushing, make careful note of how each component is installed as placement of shims, bushings, sleeves, etc., is critical.

Bushings should be lubricated according to manufacturer's instructions. Most have a grease fitting on the swing arm shaft to facilitate the operation, while others must be lubricated by hand.

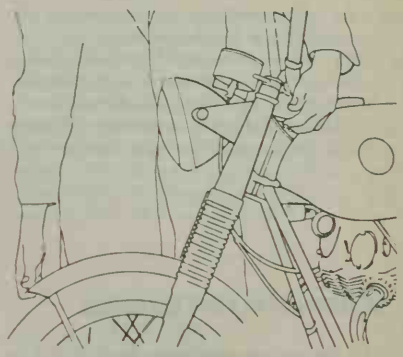
After a rebuilt swing arm is installed, tighten the shaft nut (if fitted) to the proper torque, and check for free movement of the swing arm. Movement should be relatively free (not loose) and noiseless.

New bushings should be checked carefully before installation. Be sure they are the correct ones for your machine, and that any lubrication holes or grooves which are supposed to be there are there.

STEERING STEM

The steering stem assembly consists of the upper and lower triple clamps, their connecting shaft, and the bearings on which the assembly rides in the frame lug.

The bearings in most cases are uncaged balls which ride on bearing races, the inner halves of which are pressed into the frame lug.



The condition of the steering stem bearings should be checked periodically in the following manner:

a. Support the front wheel of the motorcycle off the ground.

b. Grasp the fork sliders, and attempt to move them back and forth in line with the motorcycle. No play should be noted here. An alternate method, applicable to machines with a sturdy front fender is to grasp the tip of the fender and pull upwards, placing your other hand at the junction of the triple clamp and frame to feel for play.

Checking steering stem bearings for adjustment

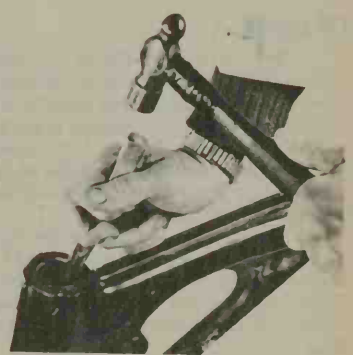
Checking steering stem bearings for play

Ordinarily, play indicated by either of these two methods can be remedied by simply adjusting the bearings. There is, in most cases, a nut or nuts beneath the upper triple clamp which are used to make this adjustment.

c. With the front wheel free of the ground, and any steering damper loosened or disconnected, turn the forks slowly from lock to lock. Movement should be smooth, effortless, and without noise. If fork movement is rough, or if there seems to be a detent spot somewhere during the movement of the forks, the bearings or races may be worn.

d. Position the forks about 5–10° off the centered position and release them. The forks should fall to either side of their own weight. If they do not, the bearings may be too tightly adjusted.

In general, bearings which cannot be properly adjusted, or will not hold an adjustment for any length of time, can be said to be worn to the point of replacement.



For uncaged ball bearings, all of the balls and all races must be replaced at the same time.

Removal procedures vary for different types of assemblies. In all cases, however, the frame races must be driven out with a drift, and installed with a block of wood until firmly seated in the frame lug.

The outer race of the lower bearing is usually a tight fit on the steering stem and will have to be chiseled off.

If you have disassembled the steering stem for routine lubrication, you can check the condition of the balls and races after cleaning them thoroughly in solvent to remove all the old grease.

Any balls which are pitted, rusted, or

Driving out a steering head bearing race

dented will necessitate replacement of the entire bearing and race assembly.

Races themselves should be checked for a rippled surface, indentations, and other imperfections. Frame races should not be removed unless defective, since they will probably be rendered useless by the removal procedure. The same is true of the steering stem lower race.

When installing a steering stem assembly, always be sure that the proper number of balls are fitted to each race. Imbed the balls in a high grade bearing grease.

Adjust the bearings so that fork action conforms to those standards outlined above. If new frame races have been installed, make frequent checks of adjustment during the first several hundred miles, since the frame races will probably settle over a period of time.

BATTERY

GENERAL MAINTENANCE

1. The battery electrolyte level should be checked about once every two weeks, more often in warm weather.

2. Maintain the electrolyte level between the maximum and minimum marks on the battery case. This refers to batteries with transparent plastic cases which are found on the majority of motorcycles today. If the battery does not have this type of case, check level by removing the caps from each cell. Maintain the electrolyte level just above the tops of the plates.

3. Never add acid to a battery. Add *distilled water* only. Tap water in some areas contains chemical or mineral impurities which may shorten battery life.

4. Do not overfill the battery. This may cause spillage of the electrolyte while riding.

5. Check the condition of the battery terminals. On some small batteries, the terminals are sealed and need no service. On most batteries, however, this is not the case. Terminals must be free of corrosion. Check that the connections are tight.

6. Check the battery overflow tube. It must not be blocked or pinched at any point, and must be arranged to that it will discharge any electrolyte well below any painted or plated surface. On most late models, a plate is provided on the motorcycle showing the correct routing of the overflow tube. Follow the manufacturer's instructions.

7. Check that the battery is securely mounted and that any and all straps, rubber pads, etc. provided by the manufacturer are in place and in good condition.

8. Any battery service such as cleaning, charging, etc., should not be carried out with the battery in the motorcycle. Se following sections for procedures.

9. During cold weather, keep the battery fully charged. A low battery will freeze much quicker than one with a charge. Freezing will ruin the plates even if it doesn't harm the case.

Charging

1. Battery state-of-charge is checked with an hydrometer. These are available in several sizes and prices, and range from professional models which provide a numerical specific gravity reading to less expensive units which check battery condition by indicating how many colored balls will float in the hydrometer tube.

For motorcycle use, the smaller type is recommended, since the larger model's hose may not fit through the smallish filler cap holes, and the cell may not have enough electrolyte above the plates to operate the float.

The measure of battery state-of-charge is the *specific gravity* of the electrolyte, which is nothing more than the weight of the electrolyte relative to an equal volume of water. Electrolyte with a specific gravity of 1.230, for example, is 1.230 times as heavy as water.

Note the following relations between specific gravity and battery state-of-charge, these figures being applicable at room temperature (20° C/68° F):

Electrolyte Specific Gravity	*Battery State-of-Charge*
1.260	100%
1.230	75%
1.200	50%
1.170	25%
1.140	almost none
1.110	dead

2. The battery should be recharged if the specific gravity of one or more cells shows that the battery is charged only 50% of its capacity or less (specific gravity 1.200 or less).

3. Batteries should not be charged on the motorcycle. This risks damage due to splashing electrolyte on painted or plated surfaces. It also makes it difficult to clean the case thoroughly, which should be accomplished after the battery is charged. In addition, some systems can be damaged unless the battery terminals are disconnected during charging.

4. When removing the battery, disconnect the ground side *first*. This will be the negative terminal on most motorcycles, although the positive terminal is the ground on British machines. Disconnect the battery overflow tube before removing the battery.

5. Before charging, remove the cell caps. During charging, keep a check on the electrolyte level, topping it up from time to time if necessary.

If the battery draws a lot of current from the charger, or if it gets very hot during the charging period, replacement of the battery will be necessary. Electrolyte temperatures should never exceed 110° F.

6. It is recommended that batteries be trickle-charged only at no more than 10% of their amp-hour rating. Therefore, the continuous charging rate for a 6 amp battery should be 0.6 amps. The amp-hour rating of a battery is stamped on the battery case for most batteries. Example: Yuasa battery No. 12N12A-4A indicates that the battery is a 12-volt, 12-amp-hour unit.

7. After charging, shake the battery gently to allow any trapped air bubbles to escape. Allow the battery to cool to normal temperature before checking state-of-charge.

8. After charging is completed, top up the electrolyte level if necessary, and install the cell caps. Clean off the top and sides of the battery case with a solution of warm water and baking soda. Be extremely careful that this solution does not enter the cells, since it will neutralize the acid.

9. Dirty or corroded battery terminals should be cleaned with a wire brush to ensure good contact. After the battery is installed and the terminal connections are secured, coat the terminals with petroleum jelly to reduce future corrosion.

10. When installing the battery, be sure that the overflow tube is connected and properly routed. Be sure that the battery is properly fitted. The polarity of each terminal will be clearly stamped or painted on the battery case. Even a momentary reversal of connections can destroy some electrical components.

11. Before connecting the battery, check that the cable connections are free of corrosion or oxidation. If possible, clean up the cable connectors with sandpaper.

Connect the power side of the battery first. This will be the positive terminal except on positive-ground (British) systems.

12. Ensure that the connections are tight. Check that the ground cable is securely fastened to the frame or engine. A poor ground may not prevent the motorcycle from running, but it may eventually damage electrical components on some types of systems.

Storage

1. If the motorcycle is to be out of service for any length of time, the battery should be removed and stored in a cool, dry location.

2. Trickle-charge stored batteries every month.

Troubleshooting

1. If the electrical system goes completely dead suddenly, chances are that the trouble is either a fuse or a bad electrical connection somewhere in the circuit.

Most motorcycles are fitted with an in-line fuse on the battery positive lead usually right in the neighborhood of the battery itself. Check this fuse first.

Next, check that the battery terminal connections are clean and tight. It is possible for a bad connection to show up here for seemingly no reason all of a sudden. Even if the connections seem okay, disconnect the wires at the terminals and clean them off. Sometimes you will find that the electrical system suddenly has power again while you are in the process of disconnecting the battery. In this event you can be sure that a poor electrical connection was causing the trouble.

Other electrical connections should also be checked before suspecting the battery itself in case of a sudden failure such as we are dis-

cussing here. Most motorcycles have a large number of male-female connectors either in the headlight, under the gas tank, or under one of the side covers. These connectors can come apart, corrode, or fill with water.

2. If the battery self-discharges, check that the battery case has not become impregnated with sulphuric acid. This can be done by checking the resistance of the case with an ohmmeter. Hold one probe against the case near the positive terminal, the other to the case near the negative terminal. Resistance must be infinite. Sometimes acid on the top of the battery will form a current path between the terminals, causing the battery to discharge itself. If this is the case, it may be possible to save the battery for a while by sprinkling baking soda over the top, letting it set for several minutes, and then washing it off with warm water. Take care not to let any of this get into the cells.

3. If one cell seems to lose more electrolyte than the others, check its charge with an hydrometer. It is probably shorted. Replace the battery if any cell is shorted or will not hold a charge.

4. Whitish sulfate deposits on the battery plates is a usual sign of battery age indicating that replacement will be in order soon. It may be possible to prolong the life of a sulfated battery by charging it at half the usual rate for twice the normal time.

TROUBLESHOOTING

Troubleshooting Tune-Up Items

Problem	*Possible Causes*	*Inspection/Remedy*
Engine fails to start (no spark at plugs)	Ignition switched off	Turn on ignition.
	Kill button switched off	Reset.
	Battery dead	Charge battery.
	Blown fuse	Check fuse and replace if necessary.
	Loose or corroded battery terminals	Clean and secure connections.
	Spark plugs too old; worn or fouled	Clean or replace plugs.
	Spark plugs wet	Kick engine over after removing plugs to clear it. Blow plugs dry.
	Plug gap incorrect	Set to correct gap.
	Points wires disconnected; loose or corroded snap connectors	Check wiring; clean and tighten wire connectors.
	Points incorrectly gapped pitted, worn or dirty	Inspect points. Replace or clean and adjust gap.
	Spark plug cap resistors defective	Replace spark plug caps.
	Plug leads dirty, damaged, wet, or defective	Replace leads and coils.
	Ignition coils defective	Replace.
	Condenser defective	Replace.
	Points grounding out against point plate	Inspect. Check that the point wire is insulated.
	Damaged insulators at points terminal	Replace.
Engine fails to start (has spark at plugs)	Lack of fuel	Make sure petcock is on; check for fuel in the tank.
	Fuel starvation: fuel lines clogged; petcock or filter dirty; vent in gas tank cap closed up; carburetor float valve closed off	Check for fuel at the float bowl and then back through the system.
	Carburetor adjustments incorrect	Adjust.
	Ignition timing incorrect	Adjust.
	Incorrect valve adjustment	Adjust.
	Carburetor float punctured	Replace.
	Low compression: worn rings or cylinder; bent or poorly seated valves; broken or warn valve guides	Inspect top end.
	Low compression due to blown head gasket, warped head	Rebuild.
	Incorrect valve timing	Reset.
Engine is hard to start	Worn, dirty or improperly gapped plugs, or plugs too cold	Clean or replace and gap plugs or replace with correct heat range.

Spark Plug Analysis—4-Stroke Engines

Condition	Appearance	Recommendation
NORMAL 	Brown to grayish tan color and slight electrode wear. Correct heat range for engine and operating conditions.	Service and reinstall. Replace if over 10,000 miles of service.
MODIFIER DEPOSITS 	Powdery white or yellow deposits that build up on shell, insulator and electrodes. This is a normal appearance with certain branded fuels. These materials are used to modify the chemical nature of the deposits to lessen misfire tendencies.	Plugs can be cleaned. If replaced, use same heat range.

Spark Plug Analysis—4-Stroke Engines

Condition	*Appearance*	*Recommendation*
OIL DEPOSITS 	Oily coating.	Caused by poor oil control. Oil is leaking past worn valve guides or piston rings into the combustion chamber. Hotter spark plug may temporarily relieve problem, but positive cure is to correct the condition with necessary engine repairs.
CARBON DEPOSITS 	Dry soot.	Dry deposits indicate rich mixture or weak ignition. Check for clogged air cleaner, high float level, sticky choke or worn breaker contacts. Hotter plugs will temporarily provide additional fouling protection.
PREIGNITION 	Melted electrodes. Center electrode generally melts first and ground electrode follows. Normally, insulators are white, but may be dirty due to misfiring or flying debris in combustion chamber.	Check for correct plug heat range, overadvanced ignition timing, lean fuel mixtures, leaking intake manifold, and lack of lubrication.
TOO HOT 	Blistered, white insulator, eroded electrodes and absence of deposits.	Check for correct plug heat range, overadvanced ignition timing, lean fuel/air mixtures, leaking intake manifold, sticking valves, and if bike is driven at high speeds most of the time.
HIGH SPEED GLAZING 	Insulator has yellowish, varnish-like color. Indicates combustion chamber temperatures have risen suddenly during hard, fast acceleration. Normal deposits do not get a chance to blow off, instead they melt to form a conductive coating.	If condition recurs, use plug type one step colder.
SPLASHED DEPOSITS 	Spotted deposits. Occurs shortly after long delayed tune-up. After a long period of misfiring, deposits may be loosened when normal combustion temperatures are restored by tune-up. During a high-speed run, these materials shed off the piston and head and are thrown against the hot insulator.	Clean and service the plugs properly and reinstall.

Spark Plug Analysis—2-Stroke Engines

Condition	*Appearance*	*Recommendation*
NORMAL 	Correct heat range. Insulator is light tan to gray color. Few deposits present. Electrodes are not burned.	Change plugs at regular intervals, using the same heat range.

Spark Plug Analysis—2-Stroke Engines

Condition	*Appearance*	*Recommendation*
CORE BRIDGING **GAP BRIDGING**  	Combustion particles wedged or fused between electrodes or core nose.	Both core bridging and gap bridging are caused by excessive combustion chamber deposits striking and adhering to the spark plug's firing end. They originate from the piston and cylinder head surfaces. These deposits are formed by one or a combination of the following: Excessive carbon in cylinder. Use of non-recommended oils. Immediate high-speed operation after prolonged and excessive idling. Improper ratio of fuel/oil mix.
WET FOULING 	Damp or wet, black carbon coating over entire firing end. Forms sludge in some cases.	Wrong spark plug heat range (too cold). Prolonged slow speed operation. Carburetor adjustment is too rich. Improper ratio of fuel-to-oil mixture. Induction manifold bleed-off return passage obstructed. Worn or defective breaker points, resulting in lack of voltage.
ALUMINUM THROW-OFF 	Aluminum deposits adhering to electrodes and plug core.	Caused by pre-ignition source within cylinder melting aluminum alloy off piston. Do not install new plugs until piston is examined and the source of pre-ignition is determined.
OVERHEATING 	Electrodes badly eroded. Premature gap wear. Insulator has gray or white "blistered" appearance.	Incorrect spark plug heat range (too hot). Ignition timing overadvanced. "Sticky" piston rings. Engine constantly operated at slow speeds.
LOW TEMPERATURE FOULING 	Soft, sooty deposits indicate incomplete combustion. Probable causes: rich carburetion; weak ignition; retarded timing or low compression. Continuous low-speed operation or, with oil injection systems, gunning throttle at idle.	Clean or replace.

Two-Stroke Engine Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Abnormal engine noise	Piston slap; piston-to cylinder clearance too great	Check clearance.
	Knock, especially noticable at idle: worn con rod big end bearing	Replace.
	Worn small end bearing	Replace.
	Rumble at idle developing into whine at high rpm: crankshaft main bearings worn or damaged	Replace bearing(s).
	Defective or worn transmission gears or shaft bearings	Inspect and replace worn parts.
	Pinging or spark knock	Timing too advanced; Low quality gasoline.
Engine fails to start (has spark at plug)	No gas in tank; fuel petcock turned off; fuel lines clogged	Refuel; turn on petcock; check for fuel at the carburetor; disconnect and blow out fuel line.
	Engine flooded	Remove spark plug and crank engine to clear it.
	Crankcase flooded	Remove spark plug; shut off petcock; crank engine.
	Ignition timing incorrect	Reset timing.
	Improper fuel/oil mixture	Drain fuel tank and refill with proper mixture.
	Low or no compression	Blown head gasket; warped head; Worn or damaged crankshaft seals; poor seal at crankcase mating surfaces. Worn piston rings; worn bore.
	Carburetor adjustments wrong, or carburetor flooded	Adjust carburetor. Check float height.
Engine fails to start (no spark at plug)	Ignition switched off	Turn on ignition
	Kill button switched off	Reset.
	Spark plug too old; worn or fouled	Clean or replace plug.
	Spark plug heat range too cold	Replace with proper heat range plug.
	Spark plug gap incorrect	Reset gap.
	Spark plug cap resistor defective	Replace cap.
	Plug lead damaged or defective	Replace.
	Ignition coil defective	Replace.
	Condenser defective	Replace.
	Points dirty, pitted, worn, or improperly gapped	Clean and adjust or replace points.
	Breaker points wires disconnected; loose or corroded snap connectors	Check wiring; clean and tighten connections.
	Dead battery (battery-and-coil ignition)	Recharge or replace battery.
	Blown fuse	Replace.
	Loose or corroded battery terminals	Clean and secure terminals.
Engine is hard to start	Worn, dirty, or improperly gapped plug, or plug too cold	Clean or replace and gap plug or replace with correct heat range.
	Points dirty, pitted, or out of adjustment	Clean or replace and gap points.
	Carburetor idle settings wrong; pilot air or fuel passages clogged	Adjust idle settings or clean carburetor.
	Battery low (battery ignition)	Recharge or replace battery.
	Ignition timing out of adjustment	Adjust.

	Piston seizure	Determine cause.
	Carburetor mixture too lean	Take plug readings. Adjust carburetor as needed.
	Insufficient lubricant in mixture	Check oil pump cable adjustment or gas/oil mixture percentage.
	Air leaks at carburetor manifolds	Check manifold.
Engine overheats	Heavy carbon deposits on piston, exhaust port, and muffler	Decarbonize.
	Ignition timing too retarded	Adjust timing.
Engine detonates or preignites	Spark plugs too hot for application	Replace with plugs one heat range colder.
	Ignition timing too advanced	Adjust.
	Insufficient oil in fuel	Adjust oil pump cable or fuel/oil mixture percentage. Bleed oil line if necessary.
	Carburetor mixture too lean	Adjust.
	Air leaks at carb manifolds	See "Fuel System"
	Engine carbon-choked	Decarbonize head, piston, and muffler.
	Fuel octaine rating too low	Use fuel with higher octaine rating.
Engine backfires or kickstarter kicks back	Ignition timing too advanced	Adjust.
Rapid piston and cylinder wear	Ineffective or leaking air filter	Clean or replace filter element.

Four-Stroke Engine Troubleshooting

Problem	*Possible Causes*	*Inspection/Remedy*
Abnormal engine noise (top end)	Excessive tappet clearance	Adjust.
	Piston knock due to worn cylinder	Inspect and have cylinder bored if necessary.
	Excessive carbon build-up in combustion chamber	Decarbonize.
	Worn wrist pin or con rod small end	Inspect and replace if necessary.
	Misadjusted or worn cam chain	Adjust. Replace if adjustment does not quiet the chain.
	Worn cam or crankshaft sprocket	Inspect.
	Pinging or spark knock	Timing too advanced; Low quality gasoline; drain and refill tank with fresh gas.

Four-Stroke Engine Troubleshooting

Problem	*Possible Causes*	*Inspection/Remedy*
	Rumble at idle developing into whine at higher rpm: crankshaft main bearings warn or damaged	Inspect and replace if necessary.
	Knock, especially noticeable at idle, increasing with rpm: worn con rod big end bearing	Replace.
Engine fails to start (no spark at plugs)	Ignition switched off	Turn on ignition.
	Kill button switched off	Reset.
	Battery dead	Charge battery.
	Blown fuse	Check fuse and replace if necessary.
	Loose or corroded battery terminals	Clean and secure connections.
	Spark plugs too old; worn or fouled	Clean or replace plugs.
	Spark plugs wet	Kick engine over after removing plugs to clear it. Blow plugs dry.
	Plug gap incorrect	Set to correct gap.
	Points wires disconnected; loose or corroded snap connectors	Check wiring; clean and tighten wire connectors.
	Points incorrectly gapped, pitted, warn or dirty	Inspect points. Replace or clean and adjust gap.
	Spark plug cap resistors defective	Replace spark plug caps.
	Plug leads dirty, damaged, wet, or defective	Replace leads and coils.
	Ignition coils defective	Replace.
	Condenser defective	Replace.
	Points grounding out against point plate	Inspect. Check that the point wire is insulated.
	Damaged insulators at points terminal	Replace.
Spark at one plug	Defective, worn, dirty, or fouled spark plug	Switch the nonfunctioning plug to the other lead. If spark is evident, the plug is not at fault. If no spark, replace the plug.
	Defective resistor spark plug cap	Replace.
	Defective, cracked, wet or dirty plug lead	Replace along with coil.
	Dirty, misadjusted, pitted or burned breaker points	Replace.
	Breaker point wire disconnected, broken; snap connector loose or corroded; insulation torn	Check point wiring; clean and secure connector.
	One set of points grounding out against point cover or mounting plate. Damaged insulators on point wire terminal	Check paint assemblies.
	Defective condenser	Replace.
	Defective ignition coil	Replace.
Engine fails to start (has spark at plugs)	Lack of fuel	Make sure petcock is on; check for fuel in the tank.
	Fuel starvation: fuel lines clogged; petcock or filter dirty; vent in gas tank cap closed up; carburetor float valve closed off	Check for fuel at the float bowl and then back through the system.
	Carburetor adjustments incorrect	Adjust.
	Ignition timing incorrect	Adjust.
	Incorrect valve adjustment	Adjust.
	Carburetor float punctured	Replace.

Four-Stroke Engine Troubleshooting

Problem	Possible Causes	Inspection/Remedy
	Low compression: worn rings or cylinder; bent or poorly seated valves; broken or worn valve guides	Inspect top end.
	Low compression due to blown head gasket, warped head	Rebuild.
	Incorrect valve timing	Reset.
Engine is hard to start	Worn, dirty, or improperly gapped plugs, or plugs too cold	Clean or replace and gap plugs or replace with correct heat range.
	Points dirty, pitted, or out of adjustment	Clean or replace and gap points.
	Carburetor idle settings wrong; pilot air or fuel passages clogged	Adjust idle settings or clean carburetor.
	Battery low	Recharge or replace battery.
	Ignition timing out of adjustment	Adjust.
	Valves adjusted incorrectly	Adjust valves.
	Spark plug leads cracked or dirty	Replace plug leads.
	Loss of intermittently grounded wires at coil, points, or connectors	Check all connections and condition of wiring.
	Defective coils or condensers	Replace.
	Worn or improperly seating valves	Perform top end overhaul; inspect and lap valves.
	Low compression due to worn or damaged top end components	Overhaul top end.
Engine starts but refuses to run	Fuel feed problem	Check fuel supply; check fuel petcock, lines, carburetor for blocked passages; check gas tank cap vent.
	Spark plugs too cold or worn	Replace with proper heat range plugs.
	Valve clearance incorrect	Set valve clearance.
	Ignition timing incorrect	Adjust.
Engine idles poorly	Carburetor idle adjustments incorrect	Adjust idle circuit.
	Spark plugs worn, dirty, or gap too wide	Clean or replace and gap plugs.
	Spark plugs too cold	Fit the proper heat range plugs.
	Breaker point gaps incorrect	Adjust.
	Ignition timing incorrect	Adjust.
	Valves improperly adjusted	Adjust.
	Water in carburetors	Drain float bowls and gas tank if necessary and fill with fresh gas.
	Carburetor float levels wrong	Adjust.
	Air leaks at manifolds	Determine cause and rectify.
	Leaking valves	Lap valves.
	Worn valves, valve guides, valve seats	Check valve train.
	Weak spark	Check coils and condensers.
	Petcock clogged	Clean.
	Float bowl fuel level too low	Check float height.
Engine misfires when accelerating	Loose or intermittent connections in the ignition circuit	Check all connections; make sure that they are clean and tight.
	Ignition timing incorrect	Adjust.
	Gas tank cap vent clogged	Clear.
	Water in float bowls	Drain and refill with fresh mixture.
	Carburetor main jet clogged	Remove and clean.
	Air leaks at carburetor manifolds	Determine cause and remedy.
	Defective ignition coils or condensers	Replace.
	Carburetor settings wrong	Take plug readings and rejet carbs if necessary.

Four-Stroke Engine Troubleshooting

Problem	*Possible Causes*	*Inspection/Remedy*
	Very low or dead battery	Recharge or replace battery.
Engine surges or runs unevenly at steady throttle openings	Carburetor fault; mixture too lean, erratic fuel flow	Remove and inspect carburetors.
	Air leaks at carburetor manifolds	Determine cause and remedy.
	Valves improperly adjusted	Adjust.
Engine breaks up or misfires while running	Battery very low or dead	Recharge or replace battery.
	Loose or intermittent connections in the ignition circuit	Check and secure connections.
	Battery terminal come adrift	Clean and secure battery conections.
Poor low-speed operation	Incorrect ignition timing	Adjust timing.
	Carburetor idle circuit poorly adjusted	Adjust pilot screws and idle speed.
	Spark plug gap too great or plugs too cold	Use correct heat range and gap to proper specifications.
	Poor breaker point contact	Clean or replace breaker points.
	Valves improperly adjusted	Adjust.
	Carburetor fault	See "Fuel System"
Poor high-speed operation	Ignition timing too retarded	Adjust timing.
	Spark plug gap too small	Adjust gap.
	Plugs too cold	Fit plugs of the correct heat range.
	Carburetor float level too low	Adjust float level.
	Partially blocked fuel lines or petcock	Clean.
	Dirty air cleaner	Clean or replace element.
	Weak breaker point arm spring	Replace points.
	Defective ignition coils or condensers	Replace.
	Weakened valve springs	Inspect springs.
	Incorrect valve timing	Reset.
Loss of power	Incorrect valve adjustment	Adjust tappets.
	Clogged or dirty air cleaner	Clean or replace the element.
	Incorrect ignition timing	Adjust.
	Dirty carburetors	Clean.
	Valves not sealing	Lap valves.
	Valve springs weakened	Replace.
	Rings or cylinder worn	Rebuild.
	Valve timing incorrect	Reset.
	Carburetor float level incorrect	Adjust.
	Spark plug gap incorrect	Adjust.
	Engine or muffler carbon choked	Decarbonize.
	Exhaust pipe broken or loose	Secure or replace.
Engine overheats	Insufficient engine oil	Top up.
	Too lean a mixture	See "Fuel System"
	Timing too advanced	Adjust.
	Oil pump defective; oil passage blocked	Clear system.
	Engine carbon choked	Decarbonize.
Engine backfires or kick-starter kicks back	Timing too advanced	Adjust.
	Advance unit stuck	Lubricate; check for free movement.
Popping at muffler after shutting off throttle	Air leaks in muffler	Secure clamps or nuts.
	Mixture too lean	Adjust idle circuit and float level. Check for air leaks.
Exhaust smoke accompanied by oil consumption	Too much oil in engine	Set to correct level.
	Worn rings or bore	Rebuild.
	Worn valve guides or seals	Replace.
	Scored cylinder	Bore to oversize.

Four-Stroke Engine Troubleshooting

Problem	*Possible Causes*	*Inspection/Remedy*
Black smoke from exhaust pipes	Engine carboned up	Decarbonize.
Piston seizure	Low oil level	Maintain oil at proper level.
	Engine overheating due to too advanced ignition timing, insufficient toppet clearance, stuck valves	Check settings.
	Insufficient oil	Check oil pump.
Burned valves	Clearances adjusted too tightly	Replace valves; check guides; maintain adjustment.
	Timing too retarded	Adjust.
Bent valves or broken valve guides	Valve hitting piston because of incorrect valve timing, overrevving the engine, or weak valve springs	Check top end components.
Bad connecting rod bearings	Insufficient or contaminated oil	Check oil, filter, and oil pump.
	Overrevving engine	Abide by tachometer red line
	Extended use of the engine with ignition timing too advanced, high-speed misfire, etc.	
Bad crankshaft bearings	Insufficient or contaminated oil	Replace bearings.
	Overrevving engine	Abide by tachometer red line.
	Extended use of the motorcycle with one weak or misfiring cylinder	
Worn cam lobes or bearings	Insufficient or contaminated oil	Maintain oil at proper level; change filter when directed.
	Failure to allow engine sufficient warm-up	Allow at least one minute of warm-up when starting cold eninge.
	Defective oil pump or clogged oil passages in engine	Replace.
Worn cylinder and rings	Damaged or leaking air cleaner	Replace element; secure connections.
	Low oil level or contaminated oil	Maintain oil at proper level; change oil and filter at proper intervals.
	Defective oil pump	Replace.
	Failure to allow engine sufficient warm-up	Allow at least one minute for warm-up when starting cold engine.

Clutch and Transmission Troubleshooting

Problem	*Possible Causes*	*Inspection/Remedy*
Clutch slips	Clutch improperly adjusted	Adjust.
	Clutch springs weak or damaged	Replace.
	Clutch springs not correctly secured	Tighten spring bolts.
	Friction discs worn or oil-impregnoted	Check disc width and condition. Replace if necessary.
	Friction discs warped	Inspect and replace discs if necessary.
	Clutch cable has insufficient play	Adjust cable.

Clutch and Transmission Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Clutch drags	Clutch cable or clutch improperly adjusted	Adjust cable and clutch.
	Friction discs gummy	Replace friction discs.
	Steel plates warped	Replace.
	Uneven spring tension	Check springs and replace as a set if necessary.
	Transmission oil too heavy for climate, or dirty	Change oil.
Clutch noisy	Clutch hub bearing worn	Replace.
	Clutch housing gear worn or damaged	Inspect and replace if necessary.
	Excessive clearance between disc tabs and housing	Check clearance.
	Worn or damaged clutch or mainshaft splines	Replace if necessary.
Transmission grinds when shifting or shifting is difficult	Clutch improperly adjusted	Adjust.
	Engine oil too heavy for temperature	Drain and refill with correct grade of oil.
	Worn or damaged shift forks, fork pins, shift drum, shift lever, shift arm	Inspect all components.
	Mainshaft or countershaft bearings worn or shafts bent	Inspect shafts and bearings.
Excessive gear noise	Insufficient lubricant in engine	Check level and refill to proper level.
	Gears worn (excessive backlash)	Inspect all gears.
	Worn transmission shaft bearings	Inspect and if necessary replace bearings.
Shift lever does not return	Weak or broken return spring	Inspect spring and replace if necessary.
Transmission will not shift	Clutch dragging	Check adjustment and condition of clutch assembly.
	Bent shift forks	Inspect and replace shift forks.
	Broken shifter return spring	Replace.
Transmission jumps out of gear	Worn transmission gear engaging dogs	Inspect gears and replace if damaged.
	Worn or bent shift forks or shift drum	Inspect and replace if necessary.
	Worn splines on countershaft or mainshaft	Inspect and replace if necessary.
	Bent gearshift shaft or damaged shift arm	Inspect components and replace if necessary.
	Worn or broken gear teeth	Inspect gears and replace any damaged or worn gears.
	Weak shift drum stopper spring	Replace.

Carburetor Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Carburetor floods repeatedly.	Float sticking due to misalignment	Correct.
	Fuel petcock left open with engine shut off	Shut off the fuel after you stop engine.
	Float punctured	Replace.

Carburetor Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Idle mixture too lean	Pilot jet too small	Replace with larger jet.
	Worn throttle slide	Replace.
	Pilot screw out of adjustment	Adjust.
Idle mixture too rich	Pilot jet too large	Replace with smaller jet.
	Dirt or foreign matter in idle passage	Dismantle and clean carburetor.
	Pilot screw out of adjustment	Adjust.
Lean mixture at sustained mid-range speeds	Jet needle set too lean	Reset needle clip at lower notch.
	Needle or main jet clogged	Remove and clean jets.
	Intake manifold air leak	Find leak and rectify.
Lean mixture at sustained high-speeds	Main jet too small	Replace with larger jet.
	Main jet clogged	Remove and clean.
	Float level too low	Remove float and adjust level.
Lean mixture during acceleration	Jets clogged	Remove and clean.
	Damaged or worn throttle slide	Replace.
	Float level too low	Adjust float height.
Lean mixture throughout throttle range	Fuel filters clogged or dirty	Remove and clean.
	Gas cap vent blocked	Blow clear.
	Damaged or worn throttle slide	Replace.
	Air leaks at corb manifold	Find leak and rectify.
Rich mixture at sustained mid-range speeds	Air cleaner dirty	Clean or replace.
	Main jet too large	Replace with smaller jet.
	Carburetor flooding	See above.
	Needle or needle jet worn	Replace.
Rich mixture at sustained high-speeds	Main jet too large	Replace with smaller size jet.
	Carburetor flooding	See above.
	Air cleaner dirty	Replace or clean.
Rich mixture throughout throttle range	Carburetor flooding	See above.
	Air cleaner dirty	Replace or clean.
Erratic idle	Air leaks	Determine source and recify.
	Dirty or blocked idle passages	Clean carburetor.
	Idle settings incorrect	Adjust ta specifications.
	Damage to pilot screw	Replace.
	Worn or damaged air seals such as a-rings or goskets	Rebuild carburetor.
	Unsynchronized carburetors on multi-carb machines	Adjust and synchronize carburetors.
	Defective auto timing advancer	Repair or replace.
	Mixture too lean	Adjust carburetor.
Engine dies when throttle is opened	Fuel flow problem	Check for sufficient fuel supply, clogged petcock or lines, clogged filters, proper float level.
	Idle mixture incorrect	Set idle speed and pilot screw to specifications; if correct, check pilot passages for clogged condition, pilot screw for damage.
	Idle mixture too lean	Check pilot screw and idle jet settings. Check throttle slide cutaway.
Engine misfires when accelerating	Fuel feed problem	Check for clogged tank cap vent, petcock filter, lines.
	Water in float bowls	Drain bowls and, if necessary, drain gas tonk.
	Carburetor main jet clogged	Remove and blow clear.
	Main jet too large	Fit smaller jet and run plug check.
	Air leaks at manifolds	Determine source and rectify.

Carburetor Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Engine misfires at high rpm	Main jet too large or too small	Change size after plug readings.
	Air cleaner clogged	Clean or replace air cleaner element.
	Air leaks	Determine cause and rectify.
	Throttle slide diaphragm ripped (CV carbs)	Replace.

Electrical Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Battery does not charge	Defective battery	Test each cell. Replace if shorted cell(s) are evident. See chapter 2.
	Battery electrolyte level low	Top up.
	Broken or shorting wires in charging circuit	Check continuity and condition or insulation of all wires.
	Loose or dirty battery terminals	Clean terminals and secure connections.
	Defective voltage regulator	Test and adjust if necessary. See chapter 7.
	Defective alternator	Replace.
	Defective rectifier	Replace.
Excessive battery charging	Defective battery (shorted plates)	Replace battery.
	Voltage regulator not properly grounded	Secure.
	Regulator defective	Adjust or replace. See chapter 7.
Unstable charging voltage	Intermittent short	Check wiring for frayed insulation.
	Defective key switch	Replace.
	Intermittent coil in alternator	Replace.
Electric starter spins, but engine does not	Broken starter clutch	Replace.
Starter does not turn over, but warning lights dim when starter button is pushed, or engine turns over slowly	Low battery, or battery connections loose or corroded	Charge or replace battery; clean and tighten terminals.
	Starter armature bushings worn	Replace starter.
Clicking sound when starter button is pushed, engine does not turn over	Battery low or terminals loose or corroded	Charge or replace battery; clean and tighten connections.
	Defective starter solenoid	Replace.
Nothing happens when starter button is pushed	Loose or broken connections in the starter switch or battery leads	Check switch connections, check battery terminals; clean and tighten battery leads.
Engine turns over slowly when starter button is pushed (cold weather)	Low or dead battery	Recharge or replace battery.
	Engine oil too heavy	Use correct viscosity oil.
Turn signal will not light	Burned out bulb	Replace.
Turn signal will not flash	One bulb burned out	Replace.
	Low battery	Charge or replace battery.
Speed of flasher varies with engine rpm	Low battery	Charge or replace battery.
	Defective flasher unit	Replace.
No spark or weak spark	Defective ignition coil(s)	Replace.
	Defective spark plug(s)	Replace.
	Plug lead(s) or wires damaged or disconnected	Check condition of leads and wires; check all connections.
Breaker points pitted or burned	Defective condenser	Replace points and condenser.

Electrical Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Carbon-fouled spark plugs	Mixture too rich	Adjust carburetors; check air cleaner.
	Plugs too cold for conditions	Use hotter plugs.
	Idle speed set too high	Adjust carburetors.
Oil-fouled spark plugs	Worn rings, cylinders, or valve guides	See chapter 4.
Spark plug electrodes burned or overheated	Spark plugs too hot for conditions	Use colder plugs.
	Engine overheating	See "Engine Troubleshooting" chart, above.
Spark plug electrodes burned or overheated	Ignition timing incorrect	Adjust. Refer to chapter 3.
	Mixture too lean	See above.

Chassis Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Excessive vibration	Engine mounting bolts loose	Secure mounting bolts.
	Broken frame	Replace frame or have damage recified by competent welder.
	Drive chain badly worn, unlubricated, or too tight; worn sprockets	Replace, lubricate, or adjust drive chain; replace sprockets.
	Loose spokes	Tighten spokes; have rim trued as soon as possible.
	Rims out-of-true	Have rims trued.
	Wheels unbalanced, especially front wheel	Balance wheels.
	Loose axle nuts	Tighten.
	Worn or loose steering head bearings	Adjust or replace bearings as necessary
	Crankshaft bearing failure	Inspect and replace if necessary.
	Carburetor out of synchronization	Perform tune-up.
Poor front fork operation	Weak, collapsed, or broken fork springs	Inspect and replace.
	Insufficient oil in forks	Refill with correct amount.
	Too much oil in forks	Drain and refill with correct amount.
	Oil of wrong viscosity being used	Use higher or lower viscosity oil to stiffen or weaken fork action.
	Noisy fork operation	Check oil level.
	Excessive clearance in slider bushings	Replace.
	Bent fork tubes	Replace.
	Dirty or contaminated fork oil	Change oil.
	Worn or leaky seals as evidenced by dirt in the fork oil or leaking around the seals	Replace oil seals.
Uncertain or wobbly handling	Worn or improperly adjusted steering head bearings	Adjust or replace the bearings.
	Low tire pressure	Inflate to recommended pressure.
	Worn or defective rear shocks (insufficient damping), or weak rear shock springs; spring not properly adjusted for load	Replace rear shocks; replace or adjust springs.
	Loose spokes	Tighten spokes; have rim trued as soon as possible.
	Rims out-of-true	Have rims trued.
	Loose axle	Secure axle nut and axle mounting hardware.
	Worn swing arm bushings	Replace.
Heavy or stiff steering	Low front tire pressure	Inflate to recommended pressure.
	Steering head bearings too tightly adjusted	Adjust.
	Steering damper too tightly adjusted	Loosen damper.
	Steering stem bent	Replace.
	Steering stem ball bearings unlubricated or damaged	Replace bearings and races.

Chassis Troubleshooting

Problem	Possible Causes	Inspection/Remedy
Pull to one side	Unequal suspension spring tension	Replace springs.
	Bent front fork or axle	Replace.
Excessive level or pedal travel with loss of braking power (disc brakes)	Air in hydraulic system	Bleed system.
	Master cylinder low on fluid	Fill master cylinder to level line and bleed system.
	Loose lever or pedal adjusting bolt	Adjust travel and secure bolt.
	Leak in hydraulic system	Rebuild system seals or hoses.
	Worn pads	Replace.
Brakes squeal (disc brakes)	Glazed pads	Clean up or replace pads.
	Improperly adjusted caliper (Honda)	Adjust caliper.
	Extremely dusty brake assembly	Thoroughly blow out assembly.
Brakes shudder (disc brakes)	Warped disc	Replace disc and pads.
	Distorted pads	Replace.
	Oil or brake fluid impregnated pads	Replace pads.
	Loose caliper or disc mounting bolts	Secure all fasteners.
Brake pads remain on disc (disc brakes)	Piston seized in bore	Rebuild caliper.
	Relief port blocked by piston in master cylinder	Rebuild master cylinder.
	Caliper out of adjustment (Honda)	Adjust.
	Caliper pivot frozen (Honda)	Clean and lubricate pivot.
Brakes do not hold (drum brakes)	Brake shoes glazed or worn	Repair or replace shoes.
	Brake shoes oil or grease impregnated	Replace shoes.
	Brake linings worn away	Replace linings.
	Brake drum worn or damaged	Replace or have drum turned down.
	Insufficient hydraulic fluid or air in brake lines	Drain system and refill with fresh fluid, then bleed system.
	Brake linkage incorrectly adjusted	Adjust linkage as necessary.
	Brake control cables insufficiently lubricated or binding	Lubricate or replace cables as necessary.
Brakes drag (drum brakes)	Lack of play in the linkage	Adjust linkage as necessary.
	Weak or damaged return springs	Replace springs as a set.
	Rusted cam and lever shaft	Replace as necessary.
Unadjustable brakes (drum brakes)	Worn brake shoe linings	Replace shoes or rotate the actuating lever a few degrees on its splined shaft (if applicable).
	Worn brake shoe cam	Replace the cam as necessary.
	Worn or damaged brake drum	Replace the drum or have it turned down.
Brakes make scraping sounds (drum brakes)	Linings worn down to the rivets	Replace the linings and have the drum turned or replaced as necessary.
	Broken brake shoe	Replace the shoes and repair or replace the drum as necessary.
	Dirt in the drum	Blow the assembly out with compressed air and replace or repair the drum as necessary.
	Scored or out of round brake drum	Repair or replace the drum as necessary.
	Broken pivot	Replace the pivot.
Brake shudder (drum brakes)	Unevenly worn shoes	Replace shoes.
	Out of round brake drum	Repair or replace drum.
Brake squeal (drum brakes)	Dirt on the linings or brake drum	Remove and clean the linings and drum.
	Worn or damaged brake linings	Replace.
	Linings glazed or hardened	Replace.
Brake gives on-off-on feeling when applied (drum brakes)	Braking on rough road surface (rod-operated brake)	None.
	Drum warped out-of-round	Have drum turned down on a lathe.

To change decimal millimeters to decimal inches, position the decimal point where desired on either side of the millimeter measurement shown and reset the inches decimal by the same number of digits in the same direction. For example, to convert 0.001 mm into decimal inches, reset the decimal behind the 1 mm (shown on the chart) to 0.001, change the decimal inch equivalent (0.039" shown) to 0.000039".

GLOSSARY OF COMMON TERMS

Accelerator pump—A small pump fitted to some carburetors which injects a charge of fuel into the intake tract in addition to that supplied by the normal metering components. Most accelerator pumps are activated by the movement of the throttle slide and are intended to aid transition from the pilot system to the mid-range system for smoother acceleration

Advance—Setting the ignition timing so that spark occurs before the piston reaches top dead center (TDC)

Alternating current (AC)—Electric current that flows first, in one direction, then in the opposite direction, continually reversing flow

Alternator—A device which produces AC (alternating current) which is converted to DC (direct current) by the rectifier to charge the car battery

Ammeter—A gauge which measures current flow (amps). Ammeters show whether the battery is charging or discharging

Ampere (amp)—Unit to measure the rate of flow of electrical current

Amp/hr. rating (battery)—Measurement of the ability of a battery to deliver a stated amount of current for a stated period of time. The higher the amp/hr. rating, the more powerful the battery

Antifreeze—A substance (ethylene glycol) added to the coolant to prevent freezing in cold weather

ATDC—After Top Dead Center

Bead—The portion of the tire which holds it onto the rim

Breaker points (or simply, "points")—An electrical switch operated by a cam which make and break the ignition coil circuit. When the circuit is broken by the opening points, the spark plug fires

BTDC—Before Top Dead Center. Spark occurs on the compression stroke, before the piston reaches top dead center

Bezel—Piece of metal surrounding headlights, gauges or similar components; sometimes used to hold the glass face of a gauge in the dash

Brake caliper—The housing that fits over the brake disc. The caliper holds the brake pads which are pressed against the discs by the caliper pistons, when the brake lever or pedal is depressed

Brake horsepower—Usable horsepower of an engine measured at the crankshaft

Brake fade—Loss of braking power, usually caused by excessive heat after repeated brake applications

Brake pad—The friction pad on a disc brake system

Brake shoe—The friction lining on a drum brake system

Block—The basic engine casting containing the cylinders

Bore—Diameter of a cylinder

Bushing—A plain, replaceable bearing of soft metal or rubber

Camshaft—A shaft that rotates at ½ engine speed, used to operate the intake and exhaust valves

Carbon monoxide (CO)—One of the by-products of the combustion process. Carbon monoxide is odorless and deadly

Choke—Usually, plate near the top of the carburetor that is closed to restrict the amount of air taken into the carburetor, making the fuel mixture richer. Some carburetors use a fuel plunger in lieu of a plate. Operating the choke lever raises the plunger from its seat, uncovering a fuel passage which allows gasoline to enter the intake tract bypassing the usual metering components and thus enrichening the mixture

Clutch—Part of the power train used to connect/disconnect power to the rear wheel

Combustion chamber—The part of the engine in the cylinder head where combustion takes place

Compression check—A test involving removing each spark plug and inserting a gauge. When the engine is cranked, the gauge will record a pressure reading in the individual cylinder. General operating condition can be determined from a compression check

Compression ratio—The ratio of the volume between the piston and cylinder head when the piston is at the bottom of its stroke (bottom dead center) and when the piston is at the top of its stroke (top dead center)

Condenser—A small device in the ignition system which absorbs the momentary surge of current produced when the breaker points open. It protects the points from burning

Coil—Part of the ignition system that boosts the relatively low voltage supplied by the battery to the high voltage required to fire the spark plugs

Connecting rod—The connecting link between the crankshaft and piston

Conventional ignition—Ignition system which uses breaker points

Coolant—Mixture of water and antifreeze circulated through the engine to carry off heat produced by the engine

Crankshaft—Engine component (connected to pistons by connecting rods) which converts the reciprocating (up and down) motion of pistons to rotary motion used to turn the driveshaft

Crankcase—The part of the engine that houses the crankshaft

Curb weight—The weight of a vehicle without passengers or payload, but including all fluids (oil, gas, coolant, etc.) and other equipment specified as standard

Detergent—An additive in engine oil to improve its operating characteristics

Detonation—Instantaneous combustion of fuel, resulting in excessive heat and pressure which can damage engine components. Fuel should burn in the cylinders in a controlled manner, rather than exploding immediately

Diode—An electrical component which allows current to flow through it in only one direction. When connected in a certain way (i.e. "bridged") four diodes will convert AC to DC, thus the rectifier

Direct current (DC)—Electrical current that flows in one direction only

Distributor—Device containing the breaker points which distributes high voltage to the proper spark plug at the proper time. Rarely used in motorcycles

DOHC—Double overhead camshaft engine. Two overhead camshafts are used—one operates exhaust valves, and the other operates intake valves

Dry charged battery—Battery to which electrolyte is added when the battery is placed in service

Dwell angle—The number of degrees on the breaker cam that the points are closed

Electrode—Conductor (positive or negative) of electric current

Electrolyte—A solution of water and sulphuric acid used to activate the battery. Electrolyte is extremely corrosive

Electronic ignition—Type of ignition system which uses no breaker points

Enamel—Type of paint that dries to a smooth, glossy finish

Ethyl—A substance added to gasoline to improve its resistance to knock, by slowing down the rate of combustion

EP lubricant—EP (extreme pressure) lubricants are specially formulated for use with gears involving heavy loads (transmission, drive boxes etc.)

Ethylene glycol—The base substance of antifreeze

Fast idle—The speed of the engine when the choke is on. Fast idle speeds engine warm-up

Filament—The part of a bulb that glows; the filament creates high resistance to current flow and actually glows from the resulting heat

Firing order—The numerical sequence in which an engine's cylinders fire

Flame front—The term used to describe certain aspects of the fuel explosion in the cylinders. The flame front should move in a controlled pattern across the cylinder, rather than simply exploding immediately

Flat spot—A point during acceleration when the engine seems to lose power for an instant

Flooding—A condition created when too much fuel reaches the cylinders; starting will be difficult or impossible

Flywheel—A heavy disc of metal attached to the crankshaft. It smooths the firing impulses of the engine and keeps the crankshaft turning during periods when no firing takes place

Foot pound—A measurement of torque (turning force)

Fuse—A device containing a piece of metal rated to pass a given number of amps. If more current than the rated amperage passes through the fuse, the metal will melt and interrupt the circuit

Gearbox—Transmission

Gear ratio—A ratio expressing the number of turns a smaller gear will make to turn a larger gear through one revolution. The ratio is found by dividing the number of teeth in the smaller gear into the number of teeth on the larger gear

Gel coat—A thin coat of plastic resin covering fiberglass panels

Generator—A device which produces direct current (DC) necessary to charge the battery

Heat range—A term used to describe the ability of a spark plug to carry away heat. Plugs with longer nosed insulators take longer to carry heat off effectively

Hydrocarbon (HC)—A combination of hydrogen and carbon atoms found in all petroleum based fuels. Unburned hydrocarbons (those not burned during normal combustion) are about .1% of exhaust emissions

Hydroplaning—A phenomenon of driving when water builds up under the tire tread, causing it to lose contact with the road. Slowing down will usually restore normal tire contact with the road

Idle mixture—The mixture of air and fuel (usually about 14:1) being fed to the cylinders. The idle mixture screw(s) are sometimes adjusted as part of a tune-up

Lacquer—A quick drying automotive paint

Lithium base grease—Chassis and wheel bearing grease using lithium as a base. Not compatible with sodium base grease

Load range—Indicates the number of plies at which a tire is rated. Load range B equals 4 ply rating; C equals 6 ply rating; and, D equals an 8 ply rating

Manifold—A casting connecting a series of outlets to a common opening, usually referring to mounts for the carburetor(s) in motorcycle use

Master cylinder—Reservoir containing hydraulic brake fluid which forces brake fluid to the caliper pistons as the brake lever or pedal is depressed

Misfire—Condition occurring when the fuel mixture in a cylinder fails to ignite, causing the engine to run roughly

Multiweight—Type of oil that provides adequate lubrication at both high and low temperatures

Nitrous oxide (NOx)—One of the 3 basic pollutants found in the exhaust emission of an internal combustion engine. The amount of NOx usually varies in an inverse proportion to the amount of HC and CO

Octane rating—A number, indicating the quality of gasoline based on its ability to resist knock. The higher the number, the better the quality. Higher compression engines require higher octane gas

OEM—Original Equipment Manufactured. OEM equipment is that furnished standard by the manufacturer

Ohm—Unit used to measure the resistance to flow of direct current

Oscilloscope—A piece of test equipment that shows electric impulses as a pattern on a screen. Engine performance can be analyzed by interpreting these patterns

Overhead camshaft—Camshaft mounted above the combustion chamber

Oxides of nitrogen—See nitrous oxide (NOx)

Percolation—A condition in which the fuel actually "boils," due to excess heat. Percolation prevents proper atomization of the fuel causing rough running

Pick-up coil—The coil in which voltage is induced in an electronic ignition

Ping—A metallic rattling sound produced by the engine under acceleration. It is usually due to incorrect ignition timing or a poor grade of gasoline

Pinion—The smaller of 2 meshing gears

Piston ring—Metal rings (usually 3) installed in grooves in the piston. Piston rings seal the small space between the piston and wall of the cylinder

Ply rating—A rating given a tire which indicates strength (but not necessarily actual plies). A 2 ply/4 ply rating has only 2 plies, but the strength of a 4 ply tire

Polarity—Indication (positive or negative) of the 2 poles of a battery

Power-to-weight ratio—Ratio of horsepower to weight of a vehicle

Ppm—Parts per million; unit used to measure exhaust emissions

Preignition—Early ignition of fuel in the cylinder, sometimes due to glowing carbon deposits in the combustion chamber. Preignition can be damaging since combustion takes place prematurely

Psi—Pounds per square inch; a measurement of pressure

Pushrod—A steel or aluminum rod between the valve lifter and the valve rocker arm in overhead valve (OHV) type engines

Rectifier—A diode or series of diodes which change Alternating to Direct Current for battery charging. Although some small motorcycles may use a single diode for this purpose (half-wave rectifiers), the overwhelming majority use four diodes connected in a bridge which yields full-wave rectification

Resin—A liquid plastic used in body work

Resistor spark plug—A spark plug incorporating a resistor to shorten the spark duration. This suppresses radio interference and lengthens plug life

Retard—Set the ignition timing so that spark occurs later (fewer degrees before TDC)

Rocker arm—A lever which rotates around a shaft pushing down (opening) the valve with an end when the other end is pushed up by the pushrod. Spring pressure will later close the valve

Rpm—Revolutions per minute (usually indicates engine speed)

Run-on—Condition when the engine continues to run, even when the key is turned off. See dieseling

Sealed beam—A modern automotive headlight. The lens, reflector and filament from a single unit

Shimmy—Vibration (sometimes violent) in the front end caused by misaligned front end, out of balance tires or worn suspension components

Short circuit—An electrical malfunction where current takes the path of least resistance to ground (usually through damaged insulation). Current flow is excessive from low resistance resulting in a blown fuse

Sludge—Thick, black deposits in engine formed from dirt, oil, water, etc. It is usually formed in engines with neglected oil changes

SOHC—Single overhead camshaft

Solenoid—An electrically operated, magnetic switching device

Specific gravity (battery)—The relative weight of liquid (battery electrolyte) as compared to the weight of an equal volume of water

Spongy lever or pedal—A soft or spongy feeling when the brake lever or pedal is depressed. It is usually due to air in the brake lines

Sprung weight—The weight of a vehicle supported by the suspension

Straight weight—Term designating motor oil as suitable for use within a narrow range of temperatures. Outside the narrow temperature range its flow characteristics will not adequately lubricate

Stroke—The distance the piston travels from bottom dead center to top dead center

Synthetic oil—Non-petroleum based oil

Tachometer—Instrument which measures engine speed in rpm

TDC—Top dead center. The exact top of the piston's stroke

Thermostat—A temperature sensitive device in the cooling system that regulates the flow of coolant

Timing chain (belt)—A chain or belt that is driven by the crankshaft and operates the camshaft

Torque—Measurement of turning or twisting force, expressed as foot-pounds or inch-pounds

Tread wear indicator—Bars molded into the tire at right angles to the tread that appear as horizontal bars when 1/16th in. of tread remains

Tread wear pattern—The pattern of wear on tires which can be "read" to diagnose problems in the front suspension

Turbocharged—A system to increase engine power by using exhaust gas to drive a compressor. As engine speed and load increases, the compressor forces a greater air/fuel mix-

ture into the cylinder. Under light load, or cruising conditions, the turbocharger "idles" and a normal air/fuel mixture reaches the cylinders

Unsprung weight—The weight of vehicle components not supported by the springs (wheels, tires, brakes, etc.)

Vacuum advance—A method of advancing the ignition timing by applying engine vacuum to a diaphragm mounted on the distributor

Valve guides—The guide through which the stem of the valve passes. The guide is designed to keep the valve in proper alignment

Valve clearance—The operating clearance in the valve train

Valve timing—The relationship between the opening and closing of the intake and exhaust valves relative to crankshaft (and hence, piston) position

Valve train—The system that operates intake and exhaust valves, consisting of camshaft, valves and springs, lifters, pushrods, and rocker arms, where applicable

Varnish—Term applied to the residue formed when gasoline gets old and stale

Viscosity—The ability of a fluid to flow. The lower the viscosity rating, the easier the fluid will flow. 10 weight motor oil will flow much easier than 40 weight motor oil

Volt—Unit used to measure the force or pressure of electricity. It is defined as the pressure needed to move 1 amp through a resistance of 1 ohm

Voltage regulator—A device that controls the current output of the alternator or generator

Wankel engine—An engine which uses no pistons. In place of pistons triangular shaped rotors revolve in specially shaped housings

Wheelbase—Distance between the center of front wheel and the center of rear wheel

Wheel weight—Small weights attached to the wheel to balance the wheel and tire assembly. Out of balance tires quickly wear out and also give erratic handling when installed on the front

Zener diode—A semiconductor used on British motorcycles for many years as a voltage regulator. When the voltage across the zener diode reached a certain point, the element would begin to conduct current, routing it to ground, thus preventing the battery from overcharging

MAINTENANCE

Common maintenance procedures are explained in detail in "General Information."

LUBRICATION

Engine

TWO-STROKE MODELS

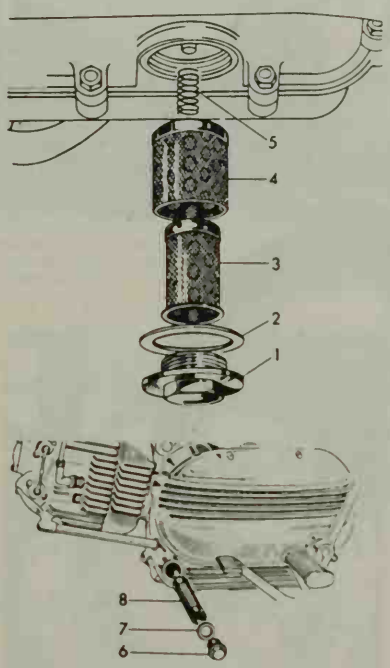
The crankshaft assembly (piston, con rod bearing, and left-side crankshaft bearing) is lubricated by the gas-oil mixture. 1973 and later models have an oil pump driven off the crankshaft which injects oil into the intake port. This system does not require maintenance except for a periodic check on the oil pump cable adjustment provided that the oil tank is kept full of oil. 1972 and earlier models use a pre-mix. When mixing the oil, on all models other than the M-100, use a ratio of one part oil to 25 parts gas (5 ounces oil to one U.S. gallon). This comes to about three measuring cupfuls (the oil cup attached to the gas tank cap) to one gallon of gas.

When mixing oil for the M-100, do so in a ratio of one part oil to 20 parts gas (6½ oz to one U.S. gal) or about four cupfuls to one gallon.

SPRINT MODELS

The transmission and engine are both lubricated by a common oil supply which is made accessible by a filler hole located on the right-side crankcase cover. When checking the oil level, unscrew the filler cap, wipe it clean, insert the dipstick but do not screw in the cap, then remove it and observe where the oil line ends. This must be done with the machine standing vertically on a flat surface. The oil level should be no higher than the "max" mark, and must never be any lower than the "min" mark.

Change the engine oil every 1,000 miles in the summer, or every 500 miles in the winter for normal use.



1. Run the engine until its normal operating temperature is reached, remove the drain plug, gasket, and the inner and outer oil filters or the oil cap assembly (1972 and later models), and allow the oil to drain into a suitable receptacle. The filter stop spring may drop off so be aware of its location.

2. Slowly kick the engine through several times with the ignition turned off to remove the last traces of oil which remain in the crankcase.

3. Clean the filters in a suitable solvent, then blow them dry. If the filter screens are clogged or damaged, they should be replaced.

4. Inspect the condition of the drain plug gasket, filter stop spring, oil filter cap, and cap O-ring for a damaged condition and replace them as necessary.

5. On 1963 and earlier models, remove the scavenger pump filter magnetic plug, plug gasket, and the filter screen, and allow the oil to drain into a suitable receptacle. Lean the bike over to the left to make sure that all the oil drains out.

3. Inner screen
4. Outer screen
5. Filter stop spring
6. Magnetic plug
7. Plug gasket (1963 & earlier)
8. Filter screen (1963 & earlier)

6. Clean the filter screen and magnetic cap in a suitable solvent and blow them dry.

7. Inspect the condition of the screen, gasket, and cap for a worn, clogged, or damaged condition and replace them as necessary.

8. Replace the drain assemblies taking care to seat the filter stop spring against the closed end of the outer filter. The inner filter closed end seats against the closed end of the onter filter, and the O-ring goes between the outer filter and the filter cap. Make sure there is no grit on the plug threads, then install and tighten them securely.

9. Add 2 qt of Harley-Davidson oil, check the level, secure the filler cap, and kick the engine through a couple times with the ignition off before starting the engine.

When changing the oil, replace it with an oil the grade of which is compatible with the lowest temperature expected before the next oil change. Use Harley-Davidson grade 58 oil for use in temperatures below 40 degrees Fahrenheit (40° F), grade 75 oil for temperatures above 40° F, and grade 105 oil for touring or high-speed operation in hot weather.

Checking Oil Pressure (Sprint)

In order for the engine to operate with a sufficient amount of lubrication, the oil pump must deliver between 3–6 psi at 25 mph in high gear The oil pump has no provision for adjustment, and must be removed and repaired if the pressure drops below the specified limits

Check the pressure by attaching Oil Pressure Gauge (H-D part no. 96921-52) and the associated hardware to the crankcase rocker arm oil feed line connection. Run the machine on the center stand until a reading can be obtained. If the pump does not check out, inspect it for blockage somewhere along the oil lines which could cut down the oil flow.

Transmission Oil

All of the two-stroke models have separate transmission compartments, for which the state of lubrication requires periodic attention. The Sprint models have a common oil supply for the engine and transmission assemblies.

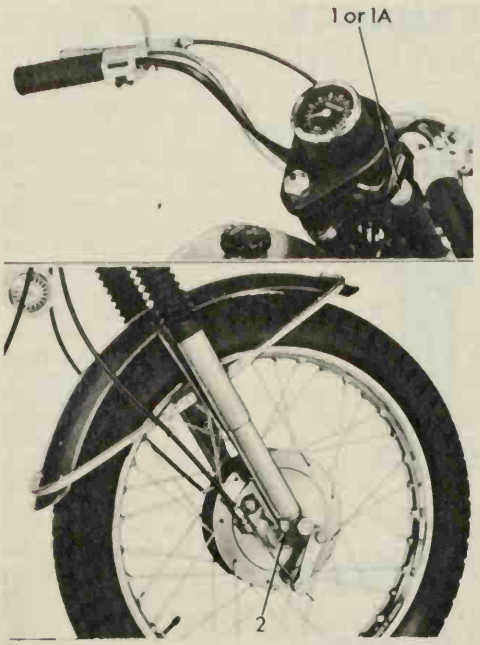
The oil level in the transmissions of all of the two-stroke models should be checked monthly or every 750 miles. The oil should be changed to suit the season, annually, every 5,000 miles, or immediately if the transmission is ever immersed in water.

Changing Fork Oil

All of the fork models except the Tele-Glide fork used on the Model 165, Hummer, Super-10, Scat, Pacer, Ranger, and the Bobcat have a filler cap located at the top of each fork leg, and a drain plug located at the bottom of each leg. The Tele-Glide model has only a filler plug located in the center of the large hex-head cap screw into which the oil is poured. Harley-Davidson Sprint Fork Oil is recommended for use in all but the Tele-Glide forks which use Harley-Davidson Chain-Saver or engine oil.

1. Remove the fork filler caps, place a suitable receptacle beneath the fork leg drain plugs, remove the drain plugs, and allow the oil to drain out. Hold the front brake on and pump the forks to remove the last of the oil. On 1969 and earlier ML and MLS Models, remove the upper fork plug, invert the forks, and let them drain.

2. If it is necessary to flush the forks to remove traces of an incompatible oil or foreign particles, fill the fork with kerosine, pump them several times, and drain them out again.



3. Replace the drain plugs and pour in the correct quantity plus 10 cc to compensate for the oil which will remain in the filler device, or ½ oz if the forks have been taken down and are perfectly dry. Refer to the "Maintenance Data" chart for capacities.

4. Replace and secure the filler caps and check the forks for smooth operation.

The Tele-Glide type forks don't require fork oil changes. Instead, the fork oil is replenished every 750 miles with one tube cap oil plug full of oil. The tube cap oil plug is located in the center of the tube caps.

Air Cleaner

The metal, mesh filter elements can be cleaned in clean gasoline or a suitable solvent. Dip the element in clean, light-viscos-

ity engine oil and allow it to drain thoroughly before installing it. Take care to place the filter gasket beneath the element when assembling the filter assembly.

The dry, corrugated paper element is cleaned by tapping the element to shake the dirt free and blowing on it with compressed air. If the element is exceptionally dirty, it may be cleaned in clean gasoline to remove oil or soot deposits. The element must be replaced at least every 10,000 miles, or more often if used in dusty conditions. Replace the element if it is ever immersed in water. This also applies to the cartridge elements (H-D part no. 29037-61) except they should be replaced every 2,500 miles.

SERVICE CHECKS AND ADJUSTMENTS

Adjusting Cone Type Wheel Hub Bearings

Bearings such as these (found on some of the M and MS models) must be adjusted every 1,000 miles to keep the wheel spinning freely on the axle with only the smallest amount of drag.

1. Axle
2. Locknut
3. Bearing cone
4. Dust caver
5. Ball bearings
6. Bearing cup
7. Outer locknut, brake side
8. Outer spacer, brake side
9. Brake sideplate
10. Inner washer, brake side

Cone type wheel hub bearings.

Adjust the bearings in the following manner:

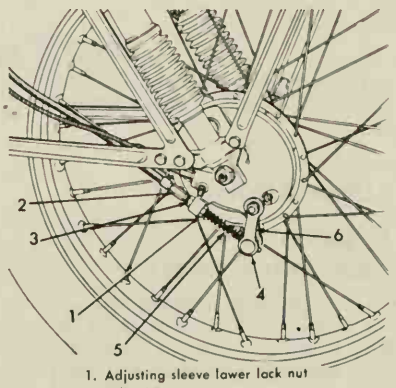
1. Remove the front wheel.

2. Loosen the wheel bearing cone locknut with a $^{11}/_{16}$ in. wrench while holding the flat sides of the cone with a 15 mm open-end wrench or a suitable adjustable wrench.

3. Rotate the cone toward the wheel until it seats snugly against the bearing, then back it off ¼ turn so there is slight play when the axle is moved sideways.

4. Secure the cone locknut when the adjustment is correct, while holding the cone to prevent it from moving.

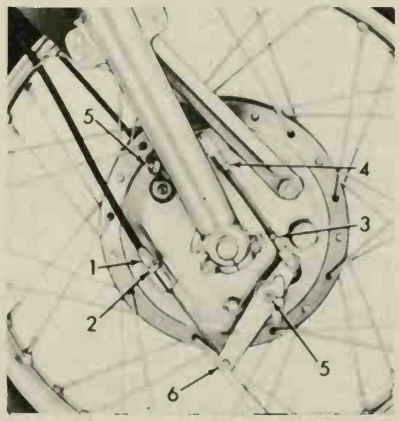
5. Mount the wheel and recheck the adjustment as it may be lost when the axle nuts are secured.



Brake Adjustment

FRONT BRAKE

When properly adjusted, the front brake lever will move about ⅛ (¼ on the S and B Models) of its total distance before the brake begins to engage. Raise the wheel, spin it to check for drag, and readjust it as necessary.



Loosen the adjusting screw locknut and rotate the adjusting screw clockwise to increase the free movement of the handlever; counterclockwise to decrease its motion. If it becomes necessary to adjust the cable length, do so by loosening the cable setscrew or clamp stud and nut, and then pulling on the cable. Always take care to secure the adjusting apparatus after the adjustment is completed.

Whenever new shoes are installed on 1970 and later Sprint models, they must be equalized to make sure that both shoes contact the drum at the same time. Perform this operation by adjusting them both at their respective ends of the brake rod clevis while holding the brake on. The clevis adjuster should be loosened before the brake is operated, and retightened before it is released.

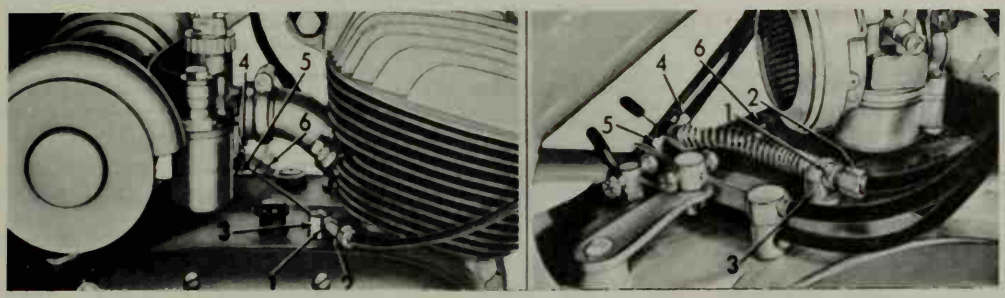
2. Locknut
3. Lower clevis adjustment
4. Upper clevis adjustment
5. Brake camshaft grease fittings
6. Cable block

Front wheel brake adjustment (1970 and later Sprint Models).

REAR BRAKE

Adjust the rear brake by turning the knurled nut, or the adjusting nut, until the brake begins to engage after the brake lever is depressed ½ in. (¾–1 in. for the S and B Models). The adjusting nut has a notch which sits against the clevis pin in the brake actuating lever to keep the adjustment constant. Turn the nut in to tighten the brake, and out to loosen it. After the adjustment is complete, raise the wheel and spin it to check for drag, and readjust it as necessary.



Clutch Adjustment

M-MODELS

All adjustments for these clutches are performed at the cable. If the clutch fails to hold and release properly after being adjusted, it will have to be taken apart to determine the reason.

Adjust the cable so the handlever moves ⅛–¼ of its total movement before the clutch begins to disengage. Loosen the cable screw locknut, turn the adjusting screw out to increase the play, or in to decrease it, and then secure the locknut.

If you run out of room at the cable adjuster, if the cable clamp has been re-

moved, or if a new cable is installed, loosen the two clamping block setscrews, screw in the adjuster so there are several threads remaining between the locknut and the crankcase anchor, tighten the setscrews while pulling on the cable with pliers to provide the necessary tension, and repeat the procedure described in the above paragraph.

S AND B MODELS

These clutches are adjusted by turning an adjusting screw which places tension directly on the push rods. The adjusting screw regulates the play in the clutch

cable which should be about ¼ of its total movement before there is a noticeable increase in tension. Adjust the clutch by loosening the adjusting screw locknut, turning the adjusting screw counterclockwise one full turn to be certain that the clutch is fully engaged, and then turning the screw clockwise until you feel the release rod contacting the release disc. At this point the clutch is beginning to disengage and there will be an increase of tension on the adjusting screw. From this point, turn the screw counterclockwise ¼ turn and secure the locknut while holding the screw steady with a screwdriver. If the clutch still fails to hold and release properly, it should be taken apart to determine the cause.

SS/SX 175/250

1. Remove three screws from the clutch adjuster cover on the right crankcase cover. Remove the adjuster cover.

2. Loosen the locknut on the lower cable adjuster, and screw the adjuster all the way into the crankcase cover. The adjuster on the handlebar should be turned out a few turns.

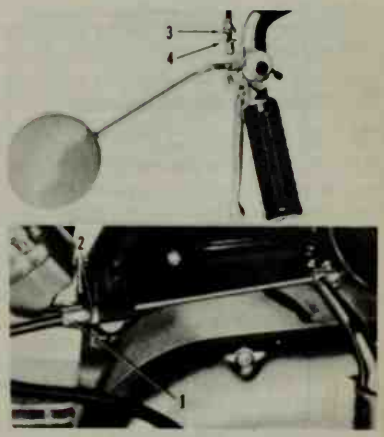
2. Cable adjuster
3. Adjusting screw locknut
4. Adjusting screw

Clutch adjustment SS/SX 175/250

3. Loosen the clutch adjuster screw locknut, and turn the adjuster screw in until resistance is felt, continue to turn the screw in two more full turns.

4. Using the lower cable adjuster remove all the slack from the cable.



5. Back the clutch adjuster screw out until it just begins to turn easily, then turn it back in until resistance is just felt. From the point where resistance is just felt back the screw out ⅛ turn to allow a small amount of free-play.

6. Using the cable adjuster on the handlebar adjust the cable free-play so that the lever can be moved ⅛–¼ in. before the clutch begins to disengage. The free-play is measured between the lever and the lever housing.

SPRINT MODELS

All adjustments for these clutches are performed at the cable. If the clutch fails to hold or release properly after being adjusted, it should be taken apart to determine the reason.

There should be play of between ⅛–¼ of the total movement of the handlever before the clutch begins to disengage. Adjust the cable at the cable adjuster screw located at the crankcase. Loosen the locknut and turn the screw clockwise, for increased play, or counterclockwise, for less play, then secure the locknut. Minor adjustments can be made at the handlever knurled nut.

2. Cable adjuster screw locknut
3. Hand lever adjuster
4. Hand lever adjuster locknut

Clutch adjustment, Sprint Models.

Chain Adjustment

Chains should be adjusted with the rear wheel on the ground and someone sitting on tne seat.

MODELS M-50 AND M-65

Loosen the axle nuts, then alternately rotate each of the adjusting nuts until there is ½ in. free-play in the middle. The chain at its tightest point. Each of the adjusting nuts must be in the same position to align the rear wheel. The wheel should be directly in the middle of the rear forks and the chain should be aligned with the rear wheel sprocket. Secure the axle nuts and adjust the rear brake when the chain is properly adjusted and aligned.

MODELS M-125, M-100, SX/SS 175/200

These models are the same as the above two, except that the adjustment is made with a cam. The cam is operated by tapping on its ear. Make sure the two sides are kept even.

S AND B MODELS

These models are adjusted in the same manner as the previous models except that the adjusting nuts are located in front of the axle nut.

SPRINT MODELS

These models are adjusted in the same manner as the previous models. The locknut must be loosened before and tightened after the adjustment procedure.

TUNE-UP

NOTE: *Common Tune-up procedures are explained in detail in "General Information."*

VALVE TAPPET ADJUSTMENT

Valves must be adjusted with the engine cold.

1. Remove the rocker arm or tappet covers.
2. Remove the spark plug and place the transmission in high gear to facilitate engine rotation.
3. Rotate the engine until either rocker arm is at the bottom of its travel (valve open). The opposite valve is now closed and may be adjusted.
4. Insert a feeler gauge between the valve stem and the rocker arm pad to measure clearance. A slight drag while removing the gauge indicates a correctly adjusted valve. Try using the next over and undersize feeler gauges to determine whether or not the selected gauge is the correct one.
5. Loosen the adjusting screw locknut to adjust the tappet.

2. Locknut (2)
3. Feeler gauge
4. Wrench
5. Screwdriver

Tappet adjustment. A box-end wrench makes a good substitute for the factory tool shown here.

6. Rotate the tappet screw clockwise to reduce clearance or counterclockwise to increase it. Secure the locknut while holding the screw steady with a screwdriver, and recheck the clearance.
7. Rotate the engine until the opposite valve is closed and repeat the above procedure.
8. Secure the cover, taking care not to damage the cover gasket.

BREAKER POINT IGNITION

Contact Breaker Points Replacement and Ignition Adjustment

M, X, Z, TX, SX125, SR MODELS

Contact Point and Condenser Replacement

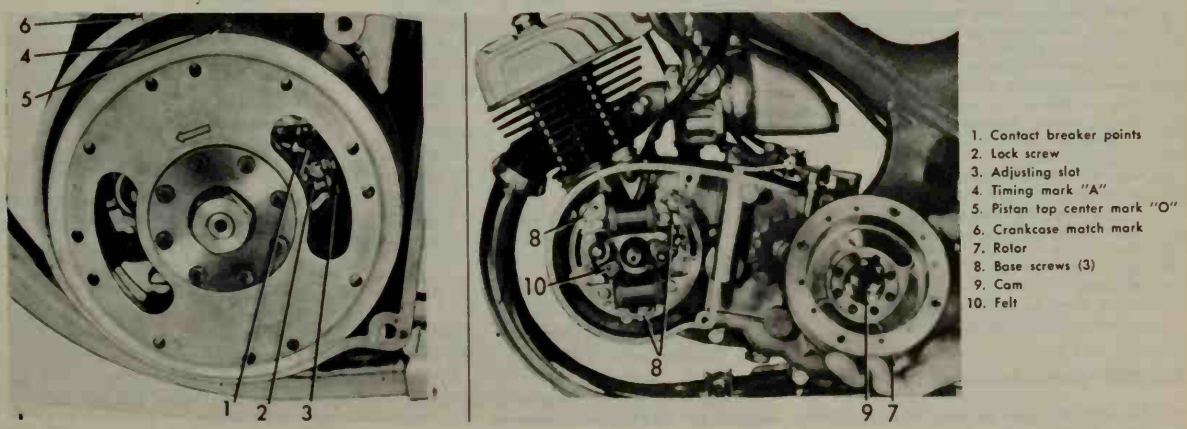
When points become excessively worn, uneven, burned, or pitted, they must be replaced in the following manner:

1. Remove the crankcase side cover as described in the "Starter" section.
2. Remove the rotor nut, washer, and rotor. The rotor may be pulled with Puller Tool (H-D part no. 97344-65P) or (97302-70M) for MSR models, or a suitable substitute.
3. Remove the contact point screw, retaining clip, and washers to free the points.
4. Replace points in the reverse order of disassembly, making sure that the point mating surfaces seat evenly against one another.

Replace the condenser while replacing the points. The condenser leads must be soldered to the magneto coil. Consult the appropriate wiring diagrams for the correct connections.

Contact Point Adjustment

1. Disconnect the spark plug and remove the crankcase side cover as described in the "Starter" section.
2. Rotate the engine until the points open to their farthest travel.
3. Insert a feeler gauge and check the gap. Gap is correctly set when there is slight drag on the gauge when moved in and out.
4. If adjustment is necessary, loosen the lockscrew and pry at the adjustment slot with a screwdriver to open or close the points as required.
5. Secure the lockscrew when the points are correctly set. Consult the specifications chart for proper setting.
6. Recheck the gap to make sure that tightening the lockscrew did not affect the adjustment.
7. Apply a few drops of engine oil to the felt cam follower oiler.



Ignition Timing Adjustment

Ignition timing should be checked whenever points are replaced, once a year, or whenever necessary. The "A" mark on the rotor indicates the proper rotor position for timing the engine and the "O" mark indicates top dead center.

1. Adjust the contact points as described in "Contact Point Adjustment."
2. Place the transmission in high gear and remove the spark plug to facilitate engine rotation. By rotating the rear wheel, the rotor may be moved to align the timing mark on the crankcase with the rotor "A" mark. The points just begin to open at this position causing spark to occur.
3. Static-time the engine using a timing light, a buzz box, or some similar device which indicates the moment the points open. A test lamp can be fabricated by wiring a 3 candle power (c.p.) taillight bulb in series with a 6 V storage battery.
4. Rotate the engine in the direction indicated by the arrow on the rotor until the timing marks align. At this point, the bulb should glow dimly or flicker rather than glow brightly as it will when the points are closed. If it does not become dim, remove the rotor as described in "Contact Point and Condenser Inspection and Replacement" and perform the following operations:

a. Loosen the base plate securing screws and shift the magneto base plate to the right to advance the timing or to the left to retard it.

b. Inserting a piece of cellophane between the points and tugging gently on it while moving the base plate will help find out when the points begin to open

since the cellophane will be released at the proper position.

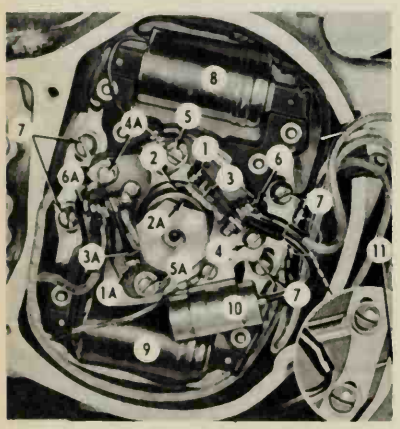
c. Secure the base screws and check to see that the point gap has not changed. Reset the gap and repeat the timing procedure if the gap has been affected.

5. Strobe-time the ignition with the engine operating at its normal operating temperature at a fast idle.

6. Aim the light at the timing marks and note whether they appear in alignment. Correct advanced or retarded timing in the same manner as described in step four.

B MODELS

Contact Point and Condenser Replacement



Replace points in the following manner:

1. Remove the sprocket and magneto-generator cover screws, then shift the cover out of the way.

2. Remove the point pivot and lockscrews from the ignition and stop light contact points.

3. Disconnect all contact point leads from their respective terminals and remove the point assemblies.

4. Replace the points in the reverse order of disassembly, making sure that the point mating surfaces seat evenly against one another.

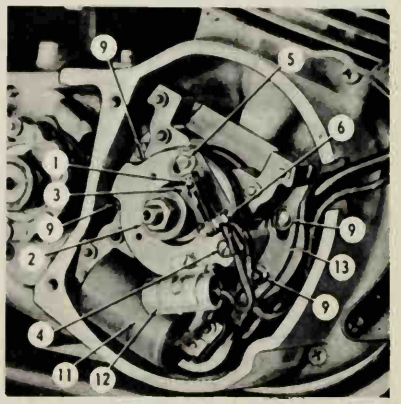
Contact Point Adjustment



The cam felt oiler should be kept lightly lubricated with engine oil.

1. Disconnect the spark plug and remove the magneto cover.

2. Rotate the engine until the cam follower is at the cam's highest point. Check the gap by inserting a 0.018 in. wire feeler gauge between the points.

3. If the points are in need of adjustment, do so in the following manner:

a. Place the transmission in high gear and rotate the rear wheel until the cam follower is at its highest point on the cam.

b. Loosen the pivot screw slightly and then the lockscrew enough to allow the point base to shift when tapped.

c. Tap the point base at the lockscrew until a gap of 0.018 in. is obtained and then secure the lock and pivot screws.

d. Check the gap.

Procedure for stop light points adjustment:

1. Perform the same operation as for the ignition points.

Ignition Timing Adjustment

The timing marks are located on the magneto base and crankcase and serve as a guide when using a timing light.

1. Remove the magneto cover and cylinder head. The cylinder may be secured in position by placing a stack of washers on the cylinder studs to approximate the thickness of the cylinder head, and then securing them with a stud nut.

2. Adjust the contact point gap as described in the previous section.

3. Rotate the engine in the manner described in the previous section until the piston reaches its highest point of travel (top dead center) then measure the distance from the top of the piston to the top edge of the cylinder bore, taking care not to move the piston.

4. Rotate the engine backward 7/32 in. from the point found in step three.

5. Loosen the base mounting screws and shift the base until the timing marks are in alignment. Clockwise movement will retard the timing and counterclockwise motion will advance it. Secure the base screws.

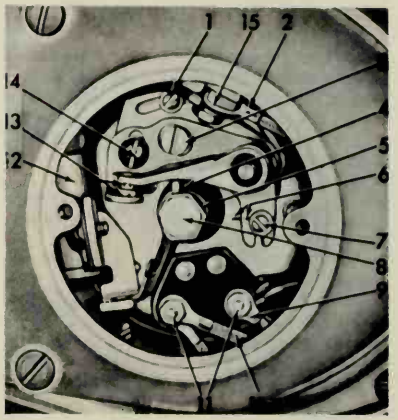
6. Check and reset the point gap, if necessary, and repeat the timing operation if the gap has changed.

7. A test light can be used as described in the Model M "Ignition Timing Adjustment" section, except that the timing is retarded when the base is moved clockwise. This method should be used if the base has been replaced and the timing marks are no longer accurate.

8. Secure the cylinder head and the magneto cover.

MODEL 165

Contact Point and Condenser Replacement



1. Remove the condenser lead from the contact point plate terminal.

2. Remove the spring lever and point from the terminal.

3. Remove the lockscrew and lift the remaining point and support plate free.

4. Replace the points in the reverse order of disassembly making sure the spring and lever notch are secured by the terminal screw between the nut and the condenser lead.

5. Bend the breaker plate, if necessary, to seat the point mating surfaces squarely against one another.

Contact Point Adjustment

1. Remove the contact breaker cover, place the transmission in high gear, and rotate the engine until the cam follower is at its highest point on the cam.

2. Check the point gap with a 0.020 in. wire feeler gauge. If the gap is in need of adjustment, do so in the following manner:

a. Loosen the point lockscrew and rotate the eccentric adjusting screw until the points are open exactly 0.020 in. when the follower is at its highest point on the cam.

b. Secure the lockscrew and check the gap. There should be a slight tugging on the gauge when trying to remove it. Check the gap by comparing the fit of the next size over and under gauges.

c. Replace the breaker cover.

Ignition Timing Adjustment

The following method is not dependent on the factory timing marks and should be performed whenever the points are replaced or at least once annually.

1. Steps 1–3 as given for the B Models.

2. Rotate the engine backward 13/64 in. from the point found in step three.

3. Loosen the point lockscrews and shift the point base so the follower is approaching the highest point of the cam and the points are just beginning to open.

4. Use a test lamp as described in the Model M "Ignition Timing Adjustment" section. The leads are connected to ground, the positive terminal, and to the black timer wire from the generator frame.

5. Secure the lockscrews and recheck the point gap. If the gap has changed, it must be reset along with the timing.

6. Secure the breaker cover and the cylinder head.

SPRINT MODELS

Contact Point and Condenser Replacement

1. Remove the contact breaker cover screws. Remove the cover by screwing 5 mm screws in the cover holes until the cover is forced off. Screws are available from your dealer (H-D part no. 2863P).

2. Remove the lockscrew and the lead to the points to remove the points from the pivot stud.

3. Replace the points in the reverse order of disassembly.

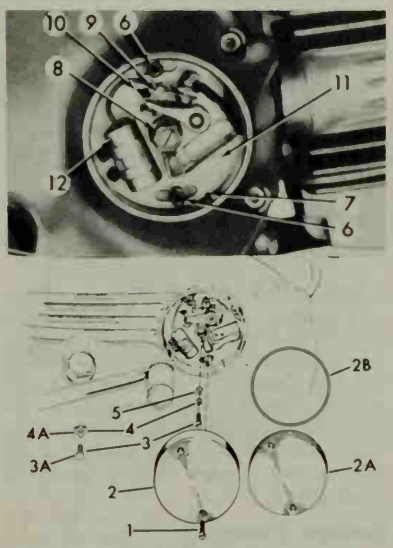
4. Bend the point contact plate to seat the point faces squarely against one another.

Contact Point Adjustment

Apply a small daub of High-Temperature Lubricant (H-D part no. 99862-72) to the cam follower taking care to avoid excessive lubrication. Engine oil or another high-quality grease may be substituted but will probably require renewal more often.

1. Remove the circuit breaker cover as described in the previous section.

2. Place the transmission in high gear and rotate the rear wheel until the points are fully open.



3. Insert a wire feeler gauge set at 0.018 in. between the points. If the gap is in need of adjustment, do so in the following manner:

a. Loosen the lockscrew.

b. Pry at the prying notch to shift the fixed contact until a gap of 0.018 in. is attained. There should be a slight tugging on the gauge when trying to remove it.

c. Secure the lockscrew and recheck the gap by inserting the next over and undersize gauges and then comparing them.

d. Replace the breaker cover.

Ignition Timing Adjustment

If the base plate has been removed or if the factory timing marks are no longer valid for any reason, static-time the engine. If a strobe light is available, a more accurate adjustment can be attained. If the timing marks are not valid, new ones may be scribed by static-timing the engine and making arbitrary marks on the base plate and crankcase.

STATIC TIMING PROCEDURE

1. Clean and adjust the contact points as described in the above section.

2. Set the advance mechanism in the advance position in the following manner:

a. Remove the breaker plate hex screws and plate.

b. Loosen the cam lockscrew.

c. Insert a wedge to spread the advance weights or place a Timing Washer (H-D part no. 97334-62 for 1968 and earlier) or a suitable substitute under the cam screw and secure the cam. This will hold the weights in the advance position.

3. Attach a test light in the following manner:

a. If the engine is installed in the frame, connect one lead to the black coil wire at its terminal and ground the other on the engine.

b. If the engine is out of the frame, connect a ground lead from the engine to the battery negative terminal and another from the points wire stud screw to the test light and from the test light to the battery positive terminal.

c. With the engine in the chassis, the light will dim as the points open and glow brightly when they close. With the engine removed from the frame, the light will glow when the points open and dim when they close.

4. Place the transmission in high gear and rotate the rear wheel until the left flywheel timing mark is in the center of the access hole. (1971 and later models), or find top dead center (TDC) with the aid of a dial gauge or by removing the head and rotating the engine until the piston is just approaching the highest point of its travel.

5. If the top dead center method is being used, consult the B Models section for measuring instructions. The piston position should be:

1961–66	13/32 in. (0.406 in.) BTDC;
1967 (original factory specification)	11/32 in. (0.350 in.) BTDC;
1967–68	1/4 in. (0.250 in.) BTDC;
1969–72	7/32 in. (0.219 in.) BTDC;
1973–74	11/32 in. (0.338 in.) BTDC.

1961	41°	21°
1962–66	41°	5°
1967–68	35°	5°
1969–72	28°	7°
1973–74	34°	12°

6. Rotate the engine in the direction of normal operation to note whether the light comes on before this position is reached. If the light comes on too early, the timing is too advanced and the base plate must be rotated clockwise. If it comes on late, the timing is too retarded and the base plate must be rotated counterclockwise. Secure the plate screws and recheck the timing. Make sure you release the advance weights before replacing the breaker cover.

STROBE LIGHT TIMING PROCEDURE (1970 AND EARLIER MODELS)

1. Remove the breaker and tachometer drive covers from the right and left sides of the crankcase respectively.

2. Install a Crankshaft Degree Indicator Tool (H-D part no. 95860-67P) in the end of the left-hand threaded generator armature and an indicator bracket on one of the crankcase screw holes. A degree wheel, such as the one in the back of the book, may be made out of cardboard or something similar, and a piece of mechanic's wire may be used as an indicator.

3. Locate TDC as described in the above section.

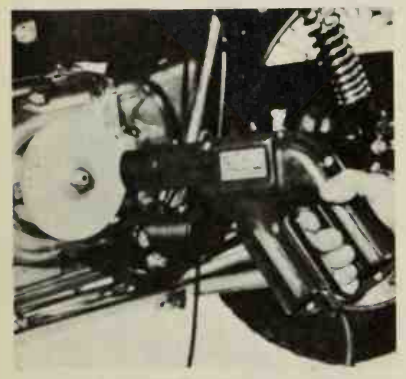
4. Adjust the indicator or degree wheel until 0° is in line with the indicator. Rotate the engine to make certain that 0° will be indicated when the piston is at TDC. Since the crankshaft will move in either direction a few degrees before the piston begins to move, 0° should be set halfway between the points at which the piston begins to move.

5. Connect the strobe leads to ground, the spark plug terminal, and the ignition coil negative terminal or as directed by the strobe manufacturer.

6. With the engine running at normal operating temperature, observe the degree

indication of the strobe light on the degree wheel. The engine was on the exhaust stroke rather than the compression stroke if the 0° reading is 180° off the indicated bracket mark position, and the degree wheel must be loosened and reset on the compression stroke.

7. With the engine operating at 4500 revolutions per minute (rpm) for advanced timing or 800 rpm for retarded timing, observe the indicated degree of crankshaft rotation and shift the breaker base until the proper position is attained.



Model Year	Advance (BTDC @ 4500 rpm)	Retard (BTDC @ 800 rpm)
1961	41°	21°
1962–66	41°	5°
1967–68	35°	5°
1969–70	28°	7°

8. Secure the breaker base and recheck the timing.

STROBE LIGHT TIMING PROCEDURE (1971–72 MODELS)

1–2 Same as above.

3. Rotate the engine until the flywheel timing mark is aligned in the inspection hole.

Strobe timing 1971 and later models.

4. Set the degree wheel so the indicator reads 28°, and secure the wheel. This relates to the flywheel timing mark which is also at 28° advance.

5. Secure the inspection hole cover to avoid oil spray.

6. Operate the engine at normal operating temperature at an idle speed of 1200–1500 rpm and observe the indicated timing with the strobe light as directed in the above section. Retarded timing should be at 7° BTDC.

7. Operate the engine at 5000 rpm to check advance timing which should be from 26–30°.

8. Adjust the breaker base as described in the above section to correct timing.

9. If repeated attempts to adjust advanced timing fail, inspect the advance unit or replace it.

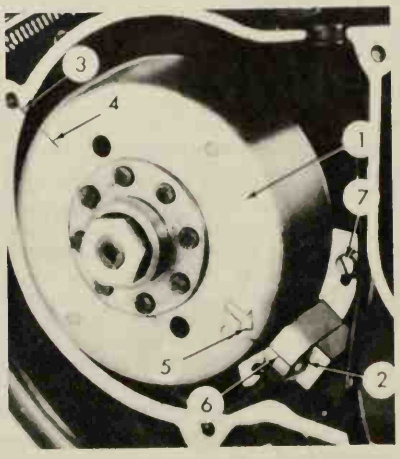
STROBE LIGHT TIMING PROCEDURE (1973–74 MODELS)

1. Remove the timing hole plug from the left crankcase cover.

2. At idle (1200–1500 rpm) the "R" mark (retard timing mark) should align with the pointer in the middle of the timing hole.

3. With the engine running at 5000 rpm the "A" mark (advance timing mark) should be visible in the timing hole.

4. The timing should be adjusted in the retarded position. If, when the retarded timing is correct, the "A" mark can not be seen in the timing hole at 5000 rpm, inspect the spark advancer for proper operation and replace if necessary.



CAPACITOR DISCHARGE IGNITION

SS/SX 175/250 models are equipped with a capacitor discharge ignition system (CDI). This type of ignition does not use contact breaker points. Instead a pick-up coil is used to trigger the silicon controlled rectifier (SCR) which then allows the capacitor to discharge the energy it has stored into the secondary winding of the coil, causing a spark to jump across the spark plug gap.

Ignition Timing

1. Ignition timing is adjusted by moving the pick-up coil so that it aligns with the arrow on the rotor when the piston is positioned 20.5° (0.1 in./2.5 mm) BTDC.

2. The piston can be positioned by aligning the slash mark on the rotor with the slash mark on the front of the crankcase. With the rotor in this position, the slash mark on the pick-up coil should be aligned with the arrow on the rotor.

When the timing marks (3 and 4) align the arrow (5) on the rotor (1) should align with the slash mark (6) on the pick-up coil (2). If adjustment is necessary, loosen the screw (7) and move the pick-up coil

3. Although the factory timing marks will provide satisfactory timing in most cases, timing can also be adjusted using a dial indicator to position the piston. If the dial indicator is to be used proceed as follows:

a. Remove the head and mount the dial indicator to the top of the cylinder so that the actuating arm rests on the top of the piston. Position the piston at TDC and zero the indicator

b. Turn the rotor in the opposite direction of normal rotation until the indicator shows the piston has moved 0.1 in. (2.5 mm). Align the pick-up coil with the arrow on the rotor.

4. Adjust the gap between the pick-up coil and the rotor to 0.012–0.016 in. (0.3–0.4 mm).

CARBURETOR ADJUSTMENT

M-50 AND M-65 CARBURETORS

1. Check to see that the throttle and choke are fully closed and adjust the throttle cable if necessary by loosening the carburetor control locknut and adjusting nut, and increasing or decreasing the cable length as required.

2. Adjust the idle with the throttle fully closed. Turning the idle stopscrew in increases the idle speed, and backing it out will decrease it.

3. On 1966 and later models, adjust the idle mixture screw to get the smoothest idle at low speeds. Avoid excessively low speeds as this will cause hard starting.

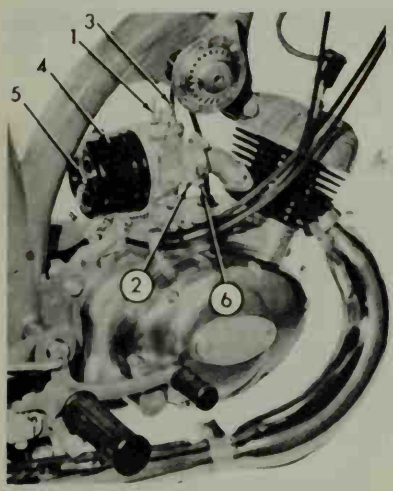
4. Adjust the mixture by altering the position of the metering pin in its clip. Raising the pin will richen the mixture and lowering it will make the mixture leaner.

Carburetor adjustments (shown is the 1965 Model M-50).

1. Choke
2. Idle stop screw
3. Carburetor control coil adjusting nut
4. Air cleaner silencer
5. Screw

The middle groove is for normal operation.

5. If additional mixture adjustments are necessary, the mainjet should be replaced.



6. If the engine still runs irregularly due to the carburetor, disassemble the carburetor and clean it thoroughly in a suitable solvent and blow all passages clear.

M-100 AND M-125 CARBURETORS

1. Adjust the idle speed by manipulating the idle stopscrew. Loosen the lockscrew and turn the stopscrew clockwise to raise the idle speed and counterclockwise to decrease it, then secure the lockscrew. Readjust the throttle cable if necessary to remove any excess play or tension.

2. Adjust the idle mixture by manipulating the idle mixture screw. The normal setting is ¾ turn off its seat but may be adjusted richer by turning it counterclockwise. If the engine runs irregularly adjust it slightly leaner.

3–6. Same as for the M-50 and M-65.

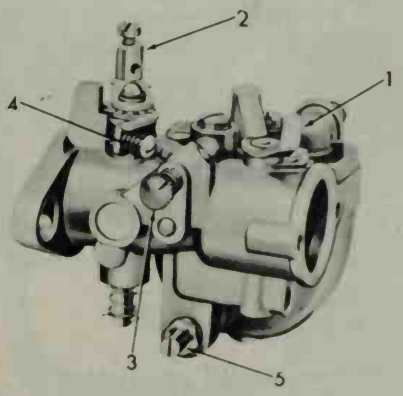
1. Choke
2. Idle stop screw
3. Carburetor control coil adjusting nut
4. Air cleaner silencer
5. Screw
6. Idle mixture screw

Carburetor adjustments (shown is the 1966 and later Models M-50 and M-65).

MODEL 165 CARBURETOR

1. Adjust the idle speed by loosening the adjusting sleeve locknut and turning the adjusting sleeve up to increase idle speed and down to decrease it. Secure the locknut.

2. The mixture is regulated by the position of the metering pin in the pin retainer. There are four positions available. The normal setting is in the second groove from the top. A richer mixture can be attained by lowering the pin (placing it in the top groove); a leaner mixture can be attained by raising the pin.



3. To adjust the pin remove the cap, spring, and throttle piston from the carburetor body. Reposition the pin as desired.

4. When replacing the control wire, take care not to bend the retainer.

5–6. Same as for the M-50 and M-65.

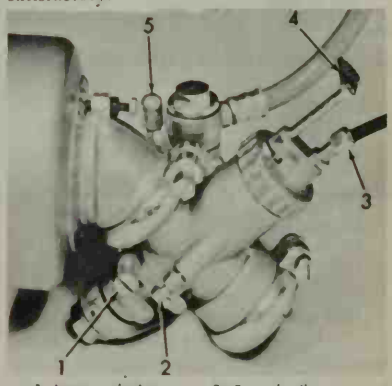
Carburetor adjustments, B Model.

2. Screw the main mixture adjusting screw gently in to its seat then back it out one full turn.

3. Open throttle halfway and hold it so the engine runs at a constant speed. Slowly turn the main adjusting screw in until the engine speed begins to decrease. Slowly back out the screw until optimum speed and power is attained. This should require no more than ¼–¼ turn.

4. Check to see that the throttle cable allows the throttle to close fully, then adjust the throttle speed slightly higher than usual by turning in the throttle stopscrew.



5. Slowly turn the idle mixture adjusting screw clockwise until the engine speed begins to decrease. Slowly back out the screw until engine operation is its smoothest. This should require no more than ⅛ turn.

6. Back out throttle stopscrew until a satisfactory idle speed is achieved. Turning the screw in raises the idle speed; backing it out reduces it.

7. If the engine still runs irregularly due to the carburetor, disassemble the carburetor and clean it thoroughly in a suitable solvent and blow all passages clear.

SPRINT CARBURETORS

1. Adjust the idle speed by loosening the locknut (1968 and earlier models) and turning the throttle piston stopscrew. Turning the screw clockwise raises the idle speed; counterclockwise reduces it. An idle speed of 1,200 rpm will prove most satisfactory.

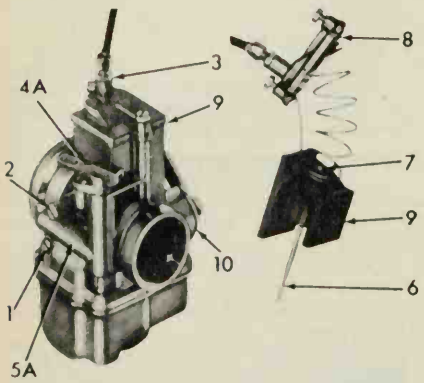
Carburetor adjustments (1968 and earlier Sprint Models).

2. Loosen the control coil adjustment screw locknut and adjust the cable to remove excessive tension or slack, then secure the locknut.



3. Turn the low-speed mixture adjusting screw gently in to its seat, then back it out ¾ turn for 1968 and earlier models and 1¾ turns for 1969 and later models. If the engine runs irregularly at low speeds, the mixture is probably too rich. Turning the screw counterclockwise on 1968 and earlier models, and clockwise on 1969 and later models, will lean out the mixture.

OIL INJECTED MODELS

1. The following adjustments should be made with the engine at normal operating temperature.
2. Use the throttle stop screw on the side of the carburetor to set the idle to 1200–1300 rpm.
3. Adjust the idle mixture with the mixture screw until the engine idles smoothly. Readjust the idle if necessary to keep it between 1200–1300 rpm.
4. Use the cable adjuster on the top of the carburetor to adjust the throttle cable free-play to near zero. This can be measured by pulling the cable sheath. The slightest movement of the sheath should raise the throttle slide.
5. Adjust the oil pump cable.

Oil Pump Cable Adjustment

1. Adjust the oil pump cable after adjusting the throttle cable.
2. Remove the oil pump cover.
3. With the throttle held in the wide open position the maximum flow mark on the pump control lever should align with the index mark on the body. If the marks do not align, use the cable adjuster to adjust the cable so that they do.

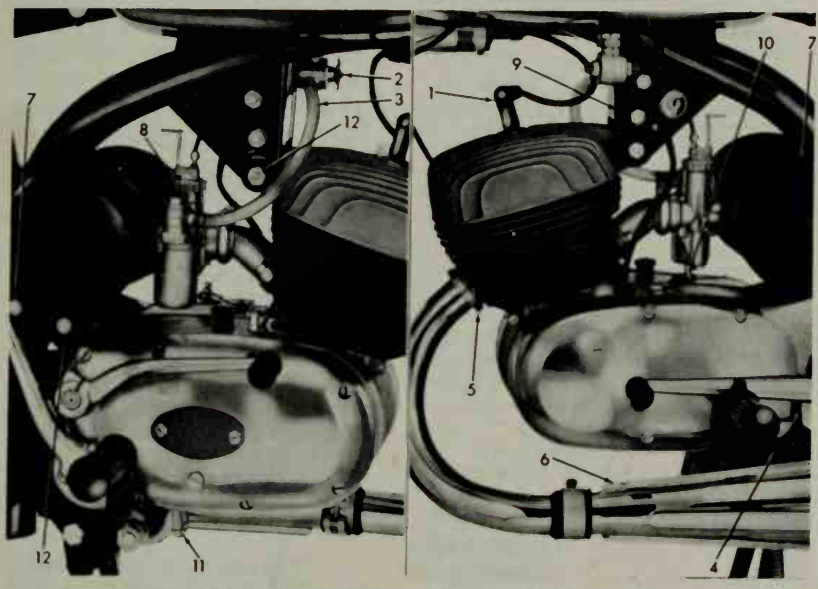
Engine Removal and Installation

MODELS M, MS, MC, X, AND Z



1. Disconnect the spark plug lead and remove the spark plug.
2. Turn off the petcock.
3. Disconnect the fuel line at the tank.
4. Remove the chain guard.
5. Disconnect the drive chain master link and remove the chain.
6. Remove the engine mounting nuts but do not remove the bolts.
7. Disconnect the clutch cable at the release mechanism.
8. Remove the exhaust manifold ring nut and gasket at the cylinder, and shift the pipe out of the way.
9. On 1973 and later models, disconnect the oil pump cable from the control lever. Unscrew the adjuster from the crankcase on the pump. Disconnect the oil pump delivery line, and plug it with a small screw to prevent oil from leaking.
10. Remove the carburetor intake manifold nuts and carburetor assembly from the engine, block the intake port with a clean cloth, and support the assembly out of the way.
11. Disconnect the wires at the terminal block.
12. Drift the front upper mounting bolt free.
13. Support the cylinder head while drifting the rear upper engine mounting bolt free. Gently lower the front end of the engine onto something soft.
14. Support the engine from below and remove the rear mounting bolt. The engine
15. Install the engine in the reverse order of removal.

MODELS ML, MLS, MSR, SR, AND SX/TX 125

1. Disconnect the spark plug lead.
2. Shut off the petcock.
3. Disconnect the fuel line at the tank.
4. Disconnect the drive chain master link and remove the chain.
5. Remove the exhaust manifold ring nut and gasket at the cylinder, and shift the pipe out of the way.
6. Remove the rear muffler mounting bolt and the exhaust assembly.
7. Remove the carburetor air cleaner assembly.
8. On 1973 and later models, disconnect the oil pump cable from the oil pump control lever. Remove the cable from the engine. Disconnect the oil lines and plug them with a small screw.
9. Remove the carburetor throttle piston cap, remove the piston, and disconnect the throttle cable.
10. Disconnect the wires at the terminal block.
11. Disconnect the clutch cable at the release mechanism.
12. Remove the bottom mounting cap nuts and washers.

Engine removal points (shown is the Model MS).

Engine removal points (shown is the Model ML).

13. Remove the rear and top engine mounting bolt nuts, lockwashers, and bolts. Be prepared to support the engine in case it tips forward.

14. Carefully support the engine in the front, pry under the bottom of the crankcase rear end to free the engine from the rubber mount, and lift the engine free.

15. Install the engine in the reverse order of removal.

MODEL 165

1. Disconnect the yellow generator lead and the black and white ground wire from the regulator terminals.

2. Remove the exhaust manifold clamp, muffler support bolt, and the exhaust assembly.

3. Remove the chain guard screws and slide the chain guard from the rear of the frame.

4. Disconnect the drive chain master link and remove the chain.

5. Remove the carburetor cover bolts and covers.

6. Remove the crankcase cover screws and cover. It is not necessary to disconnect the clutch cable and housing.

7. Disconnect the spark plug lead, and remove the spark plug and fuel line at the carburetor and tank.

8. Disconnect the throttle cable at the carburetor.

9. Disconnect the black wire from the rear fender terminal and the green wire from the fuse container, then remove the fuse and disconnect the "bat" and "gen" leads from the regulator terminal.

10. Disconnect the remaining battery lead and loosen the battery retaining strap nut until the strap, cover, and battery are free to be removed.

11. Remove the battery holder and regulator as a unit after removing the flat head screw under the battery and the top rear motor mount.

12. Remove the remaining engine mounting bolts and then the engine from the left side of the frame.

13. Install the engine in the reverse order of removal, consulting the wiring diagram for the proper electrical connections.

B-MODELS (CONSULT THE MODEL 165 ILLUSTRATION)

1. Consult the above section steps two, three, four, six, and seven.

2. Disconnect the throttle cable at the carburetor.

3. Disconnect the red magneto wire at the stop light switch, and the yellow and green magneto leads from the ignition coil.

4. Disconnect the red lead from the magneto to the ignition switch from its connection at the magneto, and remove the insulating tube (all models except BTF).

5. Disconnect the black wire from the magneto to the handlebar kill button (BTF models).

6. Remove the engine mounting bolts and the engine from the left side of the frame.

7. Install the engine in the reverse order of removal, and do the following:

a. Replace the red magneto-to-ignition switch and insulating sleeve with new ones. Soaking the tube in lacquer thinner to make it pliable will ease installation. Consult the wiring diagrams to complete all connections.

b. Tape the wires to the frame tube located beneath the crankcase.

SS/SX 175/250

1. Disconnect the spark plug lead and remove the spark plug.

2. Turn off the fuel petcock. Disconnect the fuel line from the carburetor by removing the banjo fitting.

3. Remove the exhaust system.

4. Remove the gas tank.

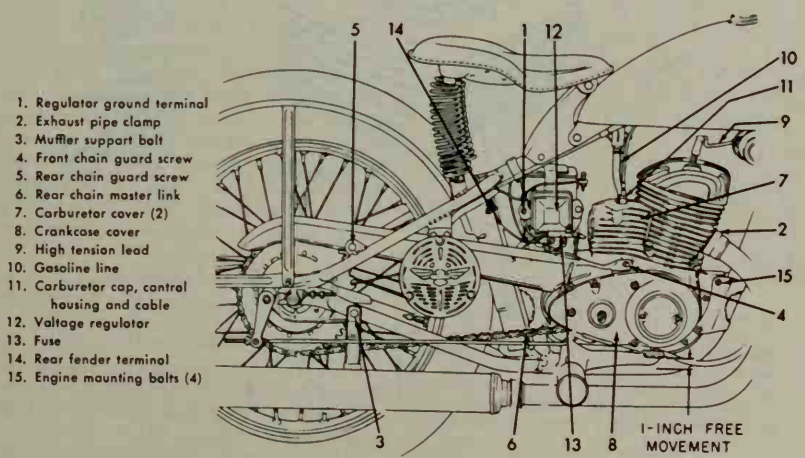
5. Remove the air cleaner. Loosen the carburetor clamp on the intake manifold, pull the carburetor back and remove it. Tie the carburetor out of the way and plug the intake port with a clean rag.

6. Remove the shift lever, and right crankcase cover. Remove the oil pump cover. Disconnect the oil pump cable from the control lever on the pump. Disconnect the oil line from the oil pump and plug the tank outlet.

7. Remove the horn.

8. Drain the oil from the crankcase.

9. Remove the drive chain masterlink and disengage the chain from the countershaft sprocket.



10. Disconnect the tachometer cable from the engine.

11. Disconnect the alternator wiring from the connector, ignition module, and the rectifier.

12. Remove the clutch cover, turn the clutch cable adjuster in, and disconnect the clutch cable from the release mechanism. Unscrew the cable adjuster and remove the cable from the engine.

13. Remove the four engine bolts and lift out the engine from the right side.

14. Install the engine in the reverse order of removal.

Cylinder and Piston

DISASSEMBLY

M, X, Z, and SX/TX 125 Models

1. Thoroughly clean the crankcase around the cylinder and blow it dry to prevent any foreign objects from falling into the crankcase.

2. Disconnect the spark plug lead, and remove the spark plug, carburetor silencer, air cleaner, exhaust pipe screw nut, and

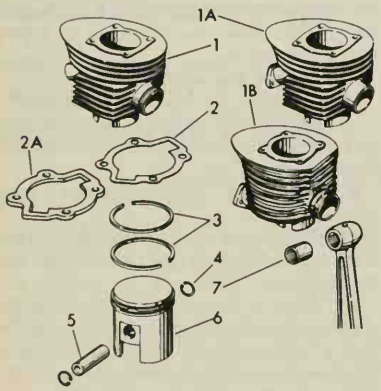
remove or shift the exhaust pipe out of the way.

3. Turn off the petcock, disconnect the gas line at the tank, and remove the carburetor at the manifold.

4. On 1973 and later models disconnect the oil line from the intake manifold by removing the banjo bolt. Place a plastic bag around the oil line and banjo fitting to prevent dirt from entering the system.

5. Remove the cylinder head nuts, washers or lockwashers, cylinder head, and head gasket (if applicable). Loosen the head if necessary by tapping gently with a wooden block and hammer.

6. Carefully work the cylinder free of the cylinder studs far enough to allow a clean, oil-soaked rag to be inserted over the crankcase opening to prevent foreign objects from falling into the crankcase. Lift the cylinder free and remove and discard the base gasket.



7. Remove the piston ring or rings by prying one end free of the piston grooves, then freeing the other end, and removing the rings while keeping them spread wide enough to clear the piston. Take care not to score the piston during this operation.

8. Using a sharp, pointed instrument, pry one of the piston pin circlips (lockring) free.

9. Press or gently tap the piston pin free by hand while firmly supporting the piston. Remove the piston and remaining circlip.

S and B Models

1. Perform all the steps in the preceding section. It will be necessary to raise the tank to provide sufficient clearance for cylinder removal. There is a cylinder spacer used on 1962 BT and BTH models.

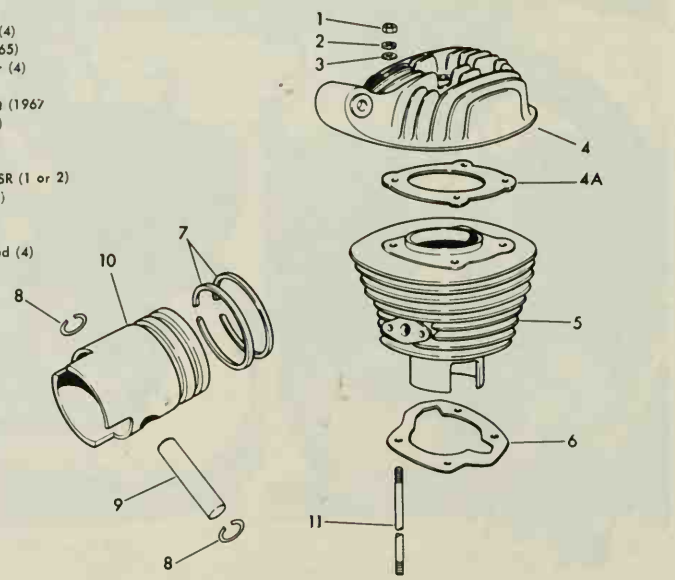
1. Clean the engine thoroughly before beginning. The areas around the cylinder head and cylinder base gaskets are particularly important.

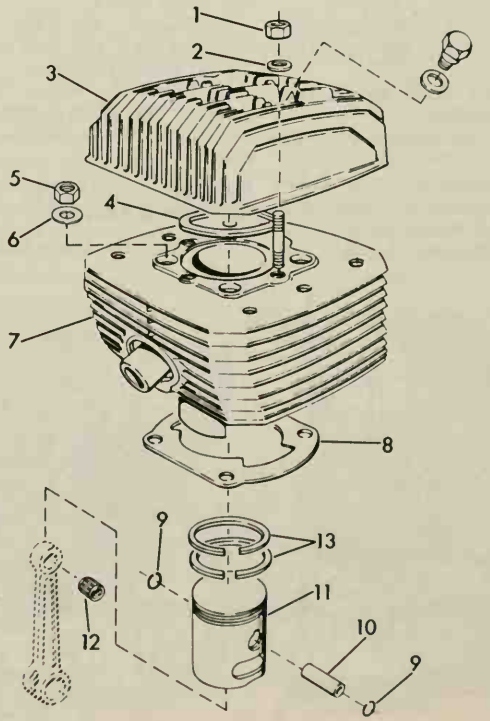
2. Remove the gas tank, and exhaust system. Remove the horn.

3. Loosen the carburetor clamp on the intake manifold, and pull the carburetor back to remove it. The carburetor can be tied out of the way with the cables connected.



4. Disconnect the oil line from the intake manifold by removing the banjo bolt. Place a plastic bag around the end of the oil line and banjo fitting to prevent dirt from entering the system.

5. Loosen the four cylinder head nuts one-quarter turn at a time, and in an "X" pattern. When all the nuts are loose, remove them and their washers from the studs. Carefully lift off the cylinder head and remove the head gasket beneath it as well.



6. Turn the engine over until the piston is at tip dead center. Remove the four nuts that secure the cylinder to the crankcase. These nuts are located in the cooling fin area. Lift the cylinder up until the cylinder spigot clears the crankcases. Insert a clean, lint-free rag between the cylinder and crankcase. Continue lifting the cylinder until the piston comes out of the bore.

7. Remove one of the wrist pin circlips and tap out the wrist pin with a suitable drift. Be careful to support the connecting

rod when tapping out the wrist pin. Removal will be easier if the piston is heated gently with a propane torch in the area of the wrist pin.

INSPECTION

The cylinder bore of the SS/SX 175/250, and SXT 125 is chrome plated aluminum. This type of cylinder cannot be bored to an oversize, and therefore, if the bore is damaged, the piston and cylinder should be replaced as a set. Pistons and cylinders are color-coded; the piston has the color mark on the crown while the cylinder is coded on the top cooling fin. When replacing these parts they should be the same color. New wrist pins and pistons are supplied in sets that are also color coded. The wrist pin is marked inside the end of the pin, while the piston is marked on the bottom of the wrist pin boss. If a new wrist pin and piston are needed, be sure to obtain one that will fit the cylinder (piston and cylinder must have same color code).

CONNECTING ROD NEEDLE ROLLER BEARING REPLACEMENT (EXCEPT SS/SX 175/250)

1. When bearings are worn or damaged, and replacement becomes necessary, either the crankcase must be disassembled so the connecting rod may be supported (a means of support must be devised if the operation is to be performed while the bottom end is still assembled) or the Piston Pin Needle Roller Bearing Tool (H-D part no. 95971-52) and Connecting Rod Clamping Tool (H-D part no. 95952-33) may be used.

2. Since there is only one size piston pin, appropriate oversize bearings must be used to take up any excess play. Consult the "Engine and Transmission Specifications Chart" for the proper clearances.

CYLINDER AND PISTON ASSEMBLY

All Models

1. Install the rings on the piston with a ring expander taking care not to break, twist, or bend the rings. The end gaps of the rings should be located over the locating pins in the ring grooves.

2. Thoroughly clean the cylinder and crankcase mating surfaces, apply a suitable gasket sealer to a new cylinder gasket, and position the gasket.

3. Lubricate the upper connecting rod bearing with engine oil.

4. Place the piston in position on the connecting rod so the arrow on the crown faces forward. Apply heat to the piston crown in a circular motion with a blow torch. Repeatedly attempt to install the piston pin by hand until it will slide in without undue force. Lightly oiling the pin may help but heat is to be mainly relied on.

5. After the piston cools, insert new circlips with the flat side (if applicable) facing out.

6. Liberally lubricate the cylinder walls, piston, and rod assembly. Slowly lower the cylinder over the piston while squeezing shut first the top two rings and then the bottom one. If the piston is not perfectly straight in the cylinder, rings may be broken. Do not change the position of the rings as dictated by the positions of the locating pins.

7. Replace the cylinder head gasket and install it in place after applying a suitable gasket sealer. On the Super-10, which uses no head gasket, apply a coat of aluminum paint to the head and cylinder mating surfaces.

8. Place the cylinder head on the cylinder mounting studs, then assemble the washers, tighten the nuts finger-tight, and secure the head nuts evenly in diagonal pairs.

9. On 1973 and later models, connect the oil line to the intake manifold with the banjo fitting. Be sure that there is a washer on either side of the fitting. Bleed the oil pump.

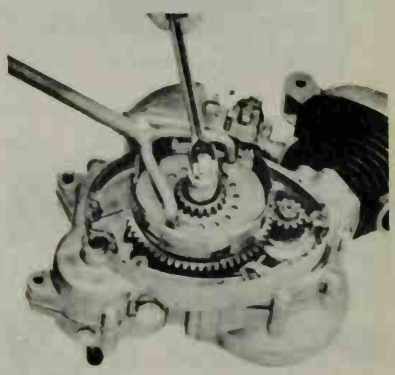
10. The remainder of assembly is the reverse of disassembly.

Clutch

DISASSEMBLY

M-50 and M-65

1. Place a drip pan beneath the clutch cover, remove the cover screws, cover, and cover gasket.



2. Compress the clutch springs with Clutch Spring Compressor (H-D part no. 97345-65P) or a suitable substitute and pry the lockring free.

3. Remove the spring plate, spring caps, springs, pressure plate, clutch discs and plates, and the clutch release pin. Use a piece of wire to lift the clutch plates and discs, then slide them out, or tip the machine over to let them slide out.

4. Remove the clutch hub nut by holding the clutch steady with Clutch Holding Tool (H-D part no. 97431-65P) and then removing the nut. Any means of holding the hub steady, such as wedging a wooden door stop between the hub gear teeth and the side of the case, will work.

8. Lift the clutch housing free, and remove the clutch housing gear nuts and bolts to free the gear if so desired.

M-100, M-125, X-90, Z-90, SR-100, and SX/TX 125

1. Place a drip pan under the clutch cover and remove the shift lever, kick-start lever, cover screws, cover, and cover gasket.

2. Remove the stud nuts by loosening them one turn each so undue pressure is not placed on the pressure plate.

3. Remove the springs, spring cups, pressure plate, clutch plates and discs, and clutch release pin. The discs and plates are easily removed with a piece of wire which can be used to lift and slide them free, or by tipping the machine over on its side to let them slide out.

4. Remove the clutch hub nut by holding the clutch steady with the Clutch Holding Tool (H-D part no. 97237-68P), or a suitable substitute, and then removing the nut. Any means of holding the clutch steady, such as wedging a wooden door stop between the hub gear teeth and the side of the case, will work.

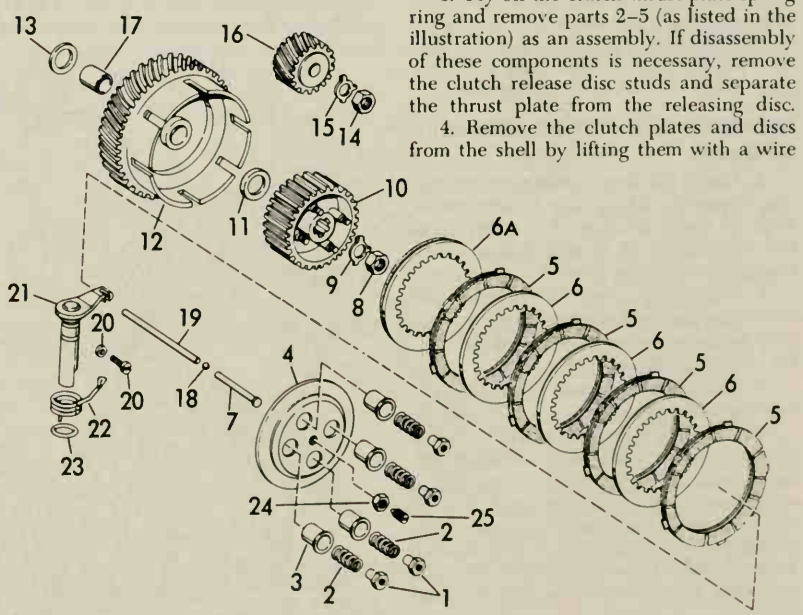
5. Remove the nut lock, clutch hub, thrust washer, clutch shell gear, and the variable-thickness spacer.

6. Secure the clutch with Clutch Holding Tool (H-D part no. 97237-68P) and remove the pinion gear nut and nut lock.

7. Pull the pinion gear with Puller (H-D part no. 97348-68P) or a suitable gear puller.

8. Remove the clutch shell gear from the shaft.

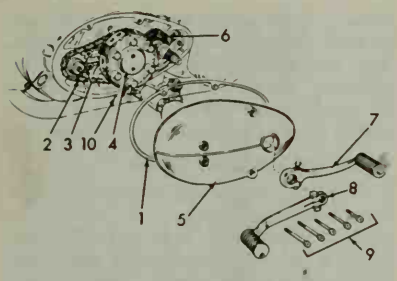
9. Remove the release lever retainer screw and washer, release lever, and the lever spring if the crankcases are to be split.



S and B Models

1. Place a drip pan under the clutch cover, remove the shift lever, kick-start lever, clutch cover screws, clutch cover, and the cover gasket.

2. Screw two Clutch Release Disc Studs (H-D part no. 37902-47) through the thrust plate and into the releasing disc, then compress the clutch springs by tightening two Compression Nuts (H-D part no. 7675) down on the studs and against the thrust plate. Studs and nuts with the appropriate size threads may be substituted.



3. Pry off the clutch thrust plate spring ring and remove parts 2–5 (as listed in the illustration) as an assembly. If disassembly of these components is necessary, remove the clutch release disc studs and separate the thrust plate from the releasing disc.

4. Remove the clutch plates and discs from the shell by lifting them with a wire

and pulling them free, or by tilting the machine over and allowing them to slide out.

5. Remove the clutch release rod and install the Clutch Lock Plate (H-D part no. 95930-48) or fabricate some means of securing the clutch such as a wooden door stop jammed between the clutch gear and the crankcase. Remove the left-hand, threaded clutch hub nut and the engine sprocket nut which has a right-hand thread, then remove the locking device.

6. Pull the clutch hub using the Clutch Hub Puller (H-D part no. 95960-48) or a suitable gear puller. Take care not to lose any of the clutch ball bearings. If any bearings are lost, they should be replaced as a complete set.

7. Loosen, but do not remove the engine sprocket using Engine Sprocket Puller (H-D part no. 95910-48) or a suitable gear puller.

8. Remove the clutch shell, primary chain, and engine sprocket as an assembly.

9. Remove the clutch bushing, bushing thrust washer, engine sprocket bearing shims, and the engine sprocket key.

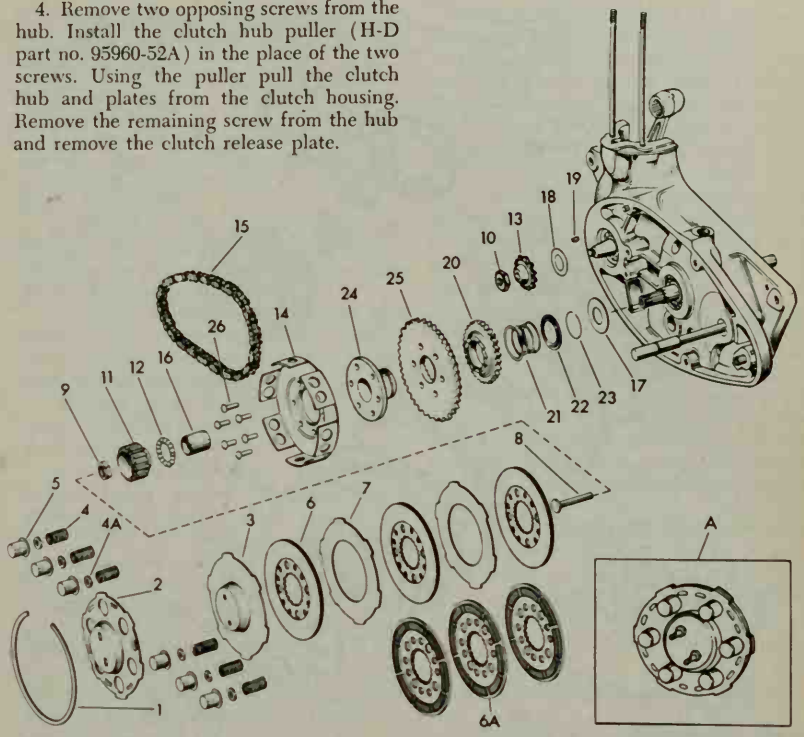
10. Pry the starter spring collar lockring from its groove and remove the starter ratchet gear, ratchet spring, and the spring collar.

11. Disassemble the release mechanism, if so desired, in the following manner:

a. Remove the sprocket cover screws and cover, disengage the clutch cable from the clutch release lever, disengage the release lever spring, and loosen the clutch adjusting screw locknut.

b. Remove the adjusting screw, dust cover, and release lever.

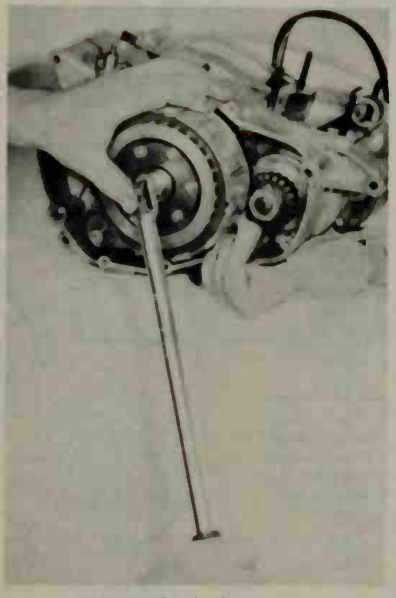
c. Drift the release rods free with an appropriately sized drift.



SS/SX 175/250 Early Clutch

1. Drain the oil from the crankcase and remove the right crankcase cover.

2. Remove the clutch release bearing assembly from the center of the clutch.



3. Bend back the tabs of the lockwasher and remove the nut from the center of the clutch hub. To prevent the hub from turning when the nut is removed, insert a soft metal wedge, or wood wedge between the primary drive gears.

4. Remove two opposing screws from the hub. Install the clutch hub puller (H-D part no. 95960-52A) in the place of the two screws. Using the puller pull the clutch hub and plates from the clutch housing. Remove the remaining screw from the hub and remove the clutch release plate.

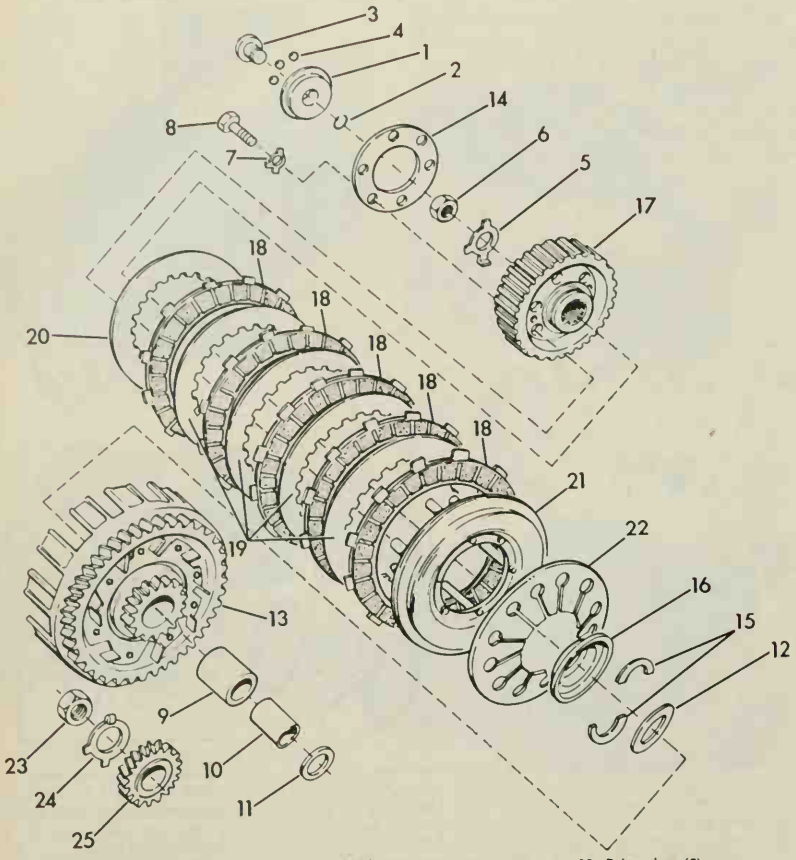
To remove the plates, mount the hub on the press and using the special tool compress the clutch spring until the two half rings can be removed. Once the two half rings are removed the components can be disassembled.



Removing the clutch hub and plates

6. Bend back the tabs of the lockwasher and remove the nut from the right end of the crankshaft. To remove the nut it may be necessary to keep the gears from turning, this can be done as before by inserting a soft metal or wood wedge between the gears.

7. Remove the clutch housing and primary gear.

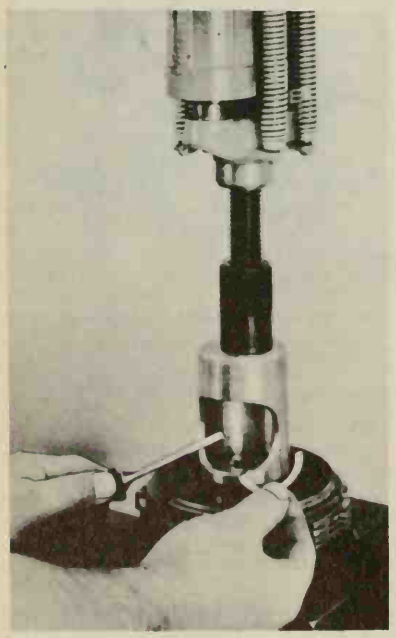
locknut on the clutch adjusting screw, and unscrew the adjusting screw. The release lever and three ball bearings can now be removed. The release plate will remain in the crankcase cover and should not be removed unless replacement is necessary.

SS/SX 175/250 Later Clutch

1. Drain the oil and remove the right right crankcase cover.

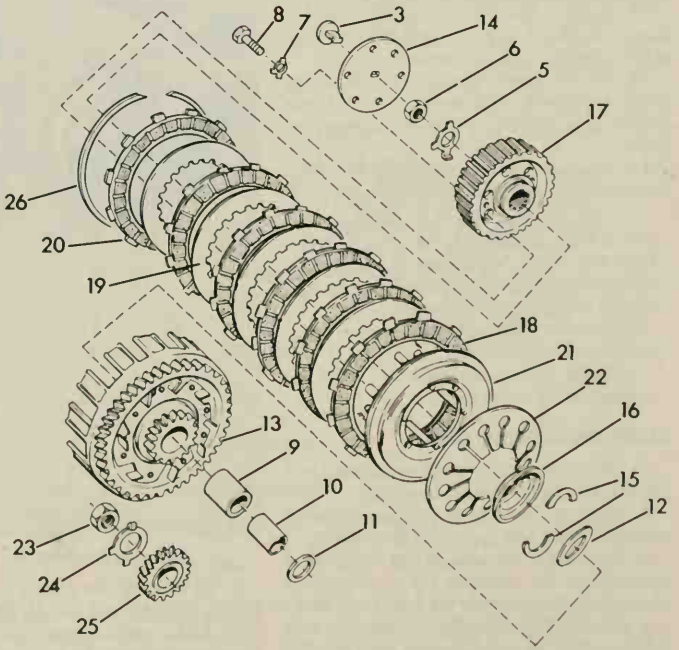
2. A special tool (H-D part no. 97354-74P) is available which will allow the clutch plates to be removed and installed without further disassembly of the clutch. If this tool is available follow steps 3 and 4 below. If the tool is not available move on to step 5.

3. Install the special tool (H-D part no. 97354-74P) onto the right crankcase. Use the tool to compress the release plate until the large ring in the clutch housing can be removed. Once the tool is removed the clutch plates can be removed.



4. To install the plates, place them in position in the clutch housing. Install the release plate. Use the special tool to compress the release plate until the large ring can be installed into the clutch housing.

5. Bend back the locktabs on the washers securing the six release plate bolts in place. Remove the six release plate bolts, and the washers beneath them.



6. Bend back the tab on the lockwasher and remove the nut from the center of the clutch hub. To prevent the clutch from turning when the nut is removed it may be necessary to insert a soft metal or wood wedge between the primary gears.

7. The clutch hub can now be removed from the mainshaft. If the hub resists removal use the factory clutch hub puller (H-D part no. 95960-52A) as described in step 5 under "Early Clutch".

8. Reinstall the release plate using two screws placed 180° apart. Mount the assembly in a press and using a suitable

9. Once the large ring is removed from the clutch housing, remove the assembly from the press. Remove the release plate, and the clutch plates from the hub.

10. To remove the spring plate, and pressure plate from the clutch housing a special tool (H-D part no. 97353-74P) and a press are needed. Mount the housing in a press with the gear side up. Position the special tool over the center of the housing and compress the spring plate until the two half rings can be removed. Once the two half rings are removed the spring plate and pressure plate can be removed from the clutch housing.

11. The release mechanism can be removed from the right crankcase cover as described in step 8 under "Early Clutch".

ASSEMBLY

M-50 and M-65

1. Assembly is in the reverse order of disassembly.

2. Grease the clutch hub thrust bearing balls with Harley-Davidson Grease-All or a suitable substitute.

3. Once the clutch hub nut is secured, check the end-play of the clutch shell gear. End-play should not exceed 0.001–0.004 in. and can be adjusted through judicious use of the variable-thickness spacer which seats against the clutch shell.

4. Replenish the oil supply and adjust the clutch as directed in the "Maintenance" section.

M-100, M-125, X-90, Z-90, SR-100, and SX/TX 125

1. Assembly is in the reverse order of disassembly.

2. The lined side of the last disc should face the crankcase wall.

3. Once the clutch hub nut is secured, check the end-play of the clutch shell gear. End-play should not exceed 0.002–0.004 in., and can be adjusted through judicious use of the variable-thickness washer which sits against the clutch shell.

4. Replenish the oil supply and adjust the clutch as directed in the "Maintenance" section.

S and B Models

1. Lubricate the pushrod tips with engine oil, then insert them in the mainshaft —the short rod first—from the right side of the motorcycle.

2. Assemble the release lever and spring to the sprocket cover, then the adjusting screw, locknut, and the worm cover loosely into the release worm.

3. Check to make sure that the lever action is smooth; lubricate it if necessary. Secure the cable end in the cover slot and lever fingers, and install the cover.

4. Place the starter ratchet gear on the clutch shell and sprocket assembly so the shell and gear teeth mesh.

5. Seat the large end of the starter ratchet spring in the indention on the starter ratchet gear, place the ratchet spring collar over the spring and compress the spring until a new spring lockring can be installed. Rotate the ratchet gear several times to make sure it operates freely.

6. Place the engine sprocket and sprocket nut on the shaft but do not permanently secure them. Using a screwdriver for leverage, press the flywheel assembly as far to the left as it will go. Measure the clearance between the back of the sprocket and the face of the ball bearing mounted in the case. Clearance should not exceed 0.003–0.012 in., and may be adjusted by inserting the appropriate number of 0.007 in. thick shims (H-D part no. 6760) behind the engine sprocket and then rechecking the clearance.

7. Secure the engine sprocket key, slip the clutch bushing thrust washer on the transmission mainshaft, engage the engine and clutch sprockets teeth in the primary chain, and install the two sprockets on their respective shafts. Secure the engine sprocket nut which has a right-hand thread.

8. Lubricate the clutch bushing with grease and install it in the clutch shell.

9. Assemble the clutch bearings in the shell, using grease to hold them in place.

10. Carefully drive the clutch hub onto the mainshaft with a suitable drift.

11. Block the motion of the clutch with Lock Plate (H-D part no. 95930-48), or a suitable substitute, and install and secure the left-hand threaded hub nut to 70 ft lbs torque. Remove the blocking device.

12. Slip the Clutch Disc Back Plate (H-D part no. 38015-49) into the shell if necessary. Slip on a fabric disc, then a steel plate, and so on until there are three discs and two plates installed other than the back plate.

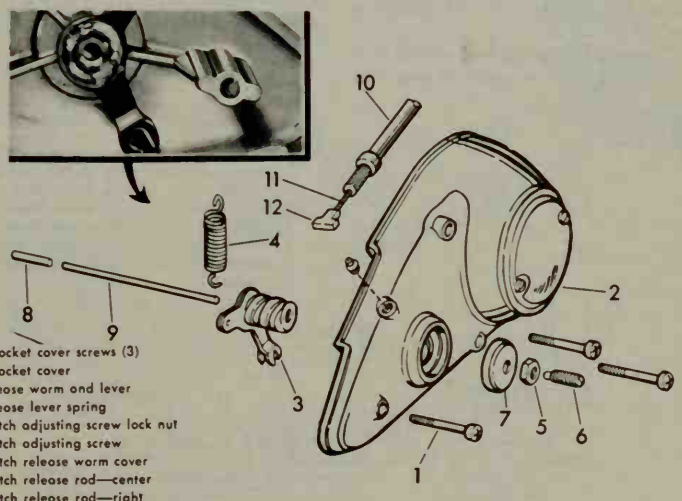
13. Lubricate the tip of the release rod in engine oil and insert it in the mainshaft.

14. Assemble the clutch releasing disc, clutch springs, spring cups, and thrust plate together, then secure the assembly with release disc studs and compression nuts. Slip the entire assembly in place and secure it with the spring ring. Once the assembly is secured, remove the compression studs and nuts.

15. Continue the assembly in the reverse order of disassembly.

16. Replenish the transmission oil supply and adjust the clutch as described in the "Maintenance" section.

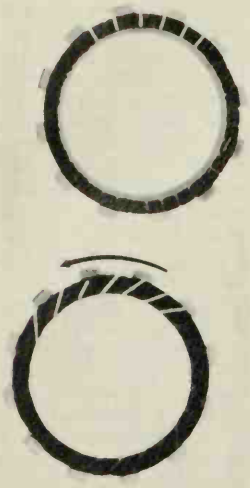
SS/SX 175/250 All Models



1. Assembly is in the reverse order of disassembly.

2. Use the special tool (H-D part no. 97353-52A) and a press to install the half rings to the rear of the hub.

3. On some models the oil drain notches in the friction plates are cut at an angle. These plates must be installed with the notches facing the opposite direction of normal clutch rotation.



4. On the later type clutch the last plate to be installed has friction material on one side. Install this plate with the friction material facing in toward the other plates.

5. On the later clutch, if the plates are being installed with the clutch assembly removed from the engine, be sure that the washer on the back of the hub is aligned with the mounting hole before installing the large ring into the clutch housing.

Kick-Starter

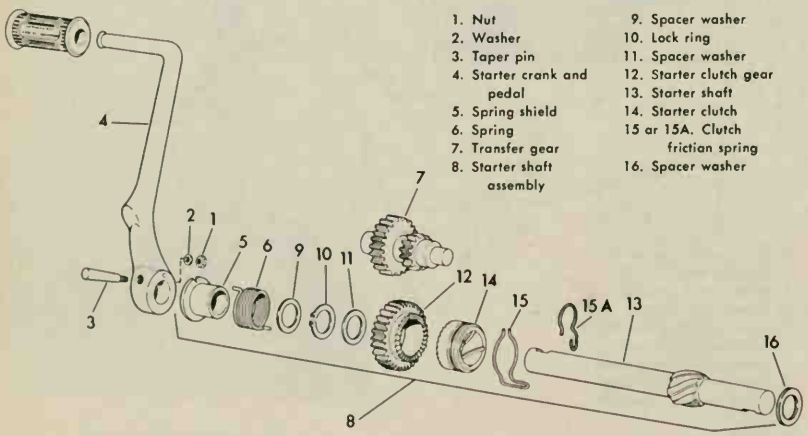
MODELS M-50 AND M-65

Disassembly

1. Remove the engine from the frame as described in the engine "Removal and Installation" section.
2. Remove the kick-starter lever taper pin nut and washer, then tap the pin out with a soft mallet, taking care not to damage the pin's threads.
3. Pull the kick-starter lever off the starter shaft with a suitable gear puller, then remove the spring shield and spring from the shaft.
4. Remove the left-side cover assembly.
5. Remove the sprocket nut and pull the sprocket from the shaft with Two-Jaw Puller (H-D part no. 97292-61) or a suitable substitute.
6. Remove the magneto-generator as described in the "Magneto-Generator" section.
7. Disassemble the crankcases as described in the "Crankcase" section.
8. Remove the transfer gear, slip the starter shaft assembly free of the transmission, and disassemble it in the following manner.

a. Remove the spacer washer and then the lockring with a pair of snap-ring pliers.

b. Slip the spacer washer and starter clutch gear from the starter shaft.



c. Slip the starter clutch and friction spring free of the shaft.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.
2. Inspect the starter clutch gear, clutch, and the transfer gear for a worn or damaged condition, paying special attention to the gear teeth. If any of the gears is in need of replacement, they should all be replaced as a set since they all mesh in one way or another.
3. Inspect the remaining components for a worn, pitted, gouged, warped, or otherwise damaged condition and replace them as necessary.

Assembly

1. Assembly is essentially the reverse of disassembly.
2. Slip the starter clutch gear and the first spacer washer on the starter shaft. These washers are available in various thicknesses from 0.2–0.8 mm to bring the shaft end-play clearances to within the specified range of 0.004–0.008 in. Temporarily install the original spacers or new ones of the same thickness as the originals.
3. Secure the lockring, then slip the next spacer onto the shaft.
4. Assemble the clutch friction spring to the clutch, then slip this assembly into place on the shaft.
5. Place the inner spacer washer, one of at least 0.4 mm thickness, on the end of the shaft and insert the shaft and transfer gear into the left crankcase taking care to properly insert the ear of the friction spring in its correct position in the crankcase.
6. Install the left side cover, then check the starter shaft end-play with a dial indicator by moving the shaft in the limit of its movement, and then pulling it out so it depresses the indicator's plunger. Avoid exerting pressure on the shaft while taking a reading, and make sure the indicator is absolutely motionless. Repeat this procedure several times to make sure the reading arrived at is accurate.
7. Disassemble the assembly once again and correct the clearance to specifications by using the appropriate spacers.
8. Once the end-play has been corrected, mount the kick-starter lever and secure it with the tapered pin, washer, and nut.

Starter assembly, M-50 and M-65.

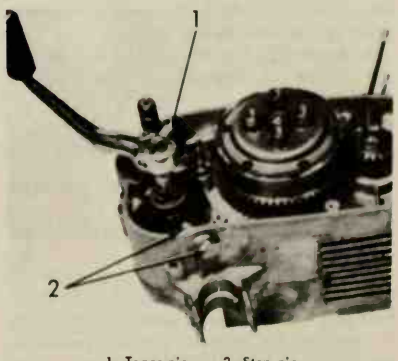
MODELS M-100 AND M-125

Disassembly

1. Remove the starter lever nut, washer, and tapered pin by tapping it out with a soft mallet, taking care not to damage its threads. Pull the lever off with a suitable gear puller.
2. Remove the gear shifter lever, clutch cover screws, and the clutch cover. Gently tap on the sides of the cover with a soft mallet to aid in removing it.
3. Remove the return spring and spring shield from the return spring stud.
4. Remove the stop pin and washer, and slip the starter shaft assembly free of the case.
5. The starter shaft assembly components freely slip off the shaft to complete the disassembly procedures.

Inspection

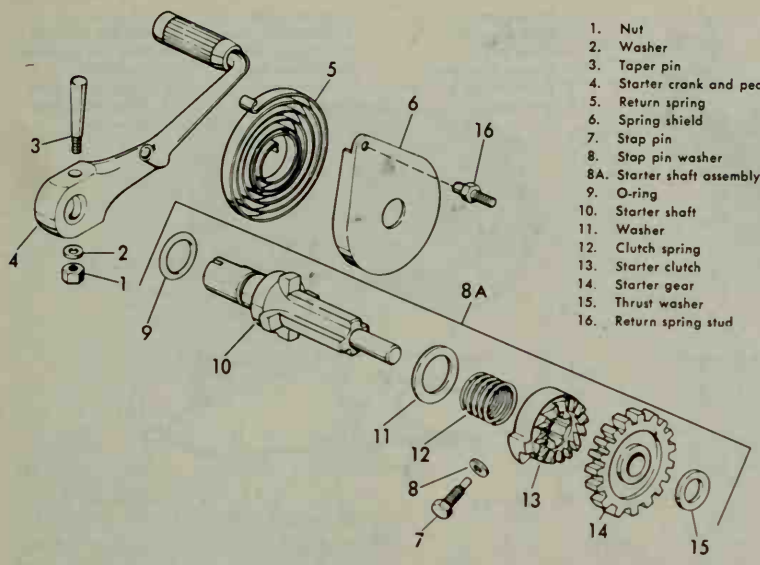
1. Clean all parts in a suitable solvent and blow them dry.
2. Inspect the gears for a worn or damaged condition, especially the gear teeth, and replace them as a set if necessary.
3. Inspect the remaining components for a worn or damaged condition and replace them as necessary. Take note of the condition of the rubber O-ring and replace it if age cracks are present.



Assembly

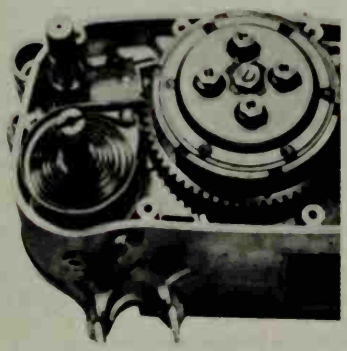
1. The correct position for the starter lever is determined by the position of the starter clutch on the splined starter shaft. Locate this position in the following manner:

a. Assemble the crankcase side thrust washer, starter gear, starter clutch, clutch spring, and the thrust washer on the starter shaft.



b. Insert this assembly into the crankcase, then install the starter lever and the stop pin washer and pin. The stop pin should engage the flat portion of the starter clutch in that position which will allow the starter lever to remain in the correct position when not in use.

2. Remove the starter lever and install the spring cover on the return spring stud.



1. Taper pin 2. Stop pin

3. Install the return spring in one of the two shaft end grooves, then rotate it to the right to bring it to the correct tension, then engage the spring end on the return spring stud.

4. Install the clutch cover, gearshift lever, press the starter lever onto the shaft, and secure it with the tapered pin, washer and nut.

S AND B MODELS

Disassembly

1. Remove the clutch cover, clutch assembly, primary chain, primary drive gear, starter ratchet gear, ratchet spring, ratchet collar, and the ratchet lockring as described in the "Clutch" section.

2. Remove the shaft thrust washer, starter shaft, sector gear, starter spring, starter spring plate, shaft spring washer, and the shaft shim.

3. Rotate the starter shaft while exerting a gentle pulling pressure on it. When the starter spring tension is relieved, the shaft assembly will be free for removal. Take care not to drop any parts into the crankcase.

4. Remove the shaft shim, spring washer, spring plate, and the spring. If these parts were not on the shaft, they may have fallen into the crankcase and therefore the cases may have to be separated to retrieve them.

5. The sector gear is a light press fit on the starter shaft and need not be removed unless inspection indicates the need for replacement.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect the ratchet and starter sector gears for a worn or damaged condition, especially at the gear teeth, and replace them as a set if necessary.

3. Inspect the engaging teeth of the ratchet and clutch sprocket gears for a worn or damaged condition and replace them as a set if necessary, as described in the "Clutch" section.

4. Inspect the ratchet spring, starter spring, and the shaft spring washer for a collapsed or damaged condition and replace them as necessary.

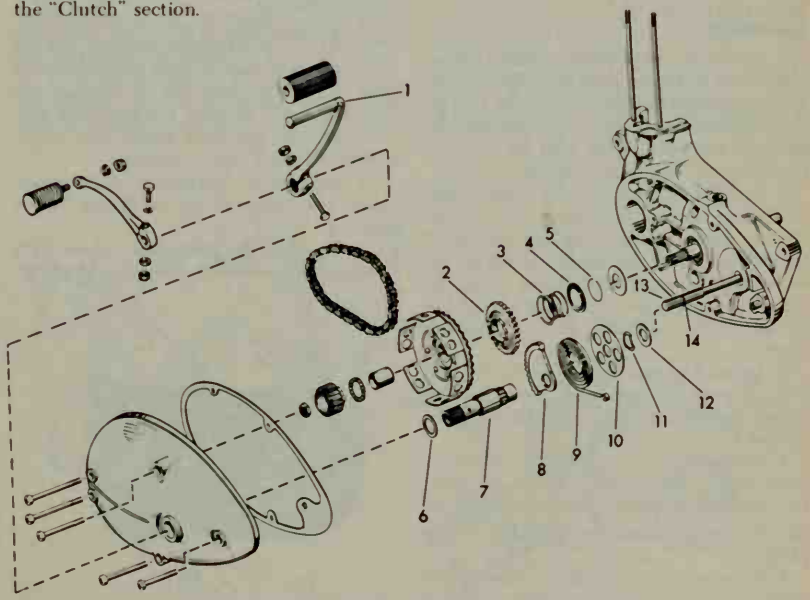
5. Replace the ratchet lockring regardless of its condition.

6. Inspect the shifter shaft oil seal for a worn, cracked, or damaged condition and replace it if necessary.

7. Inspect the remaining components for a worn or damaged condition and replace them if necessary. If the shifter shaft is warped or damaged in any way it can be replaced as directed in the "Transmission" section.

Assembly

1. Mount the starter sector gear on the starter shaft with the shoulder of the gear away from the shoulder of the shaft. The gear is a light press fit on the shaft.



2. Slip the starter spring onto the shaft so the spring rests against the sector gear, and is coiled clockwise from the center as viewed from the crankcase side.

3. Install the starter spring plate, spring washer, and the shaft shim, using a small daub of grease to hold the parts temporarily in place.

4. Lightly grease the shifter shaft oil seal, then slip the shaft assembly over the shifter shaft and engage the end loop of the starter spring with its slot in the crankcase. Take care not to allow the shim and washer to fall out of position during this operation.

5. Rotate the starter shaft slightly less than one full turn and then carefully push it in until seated against the crankcase. The sector gear should rest against its stop which keeps the assembly from rotating and therefore releasing the spring tension.

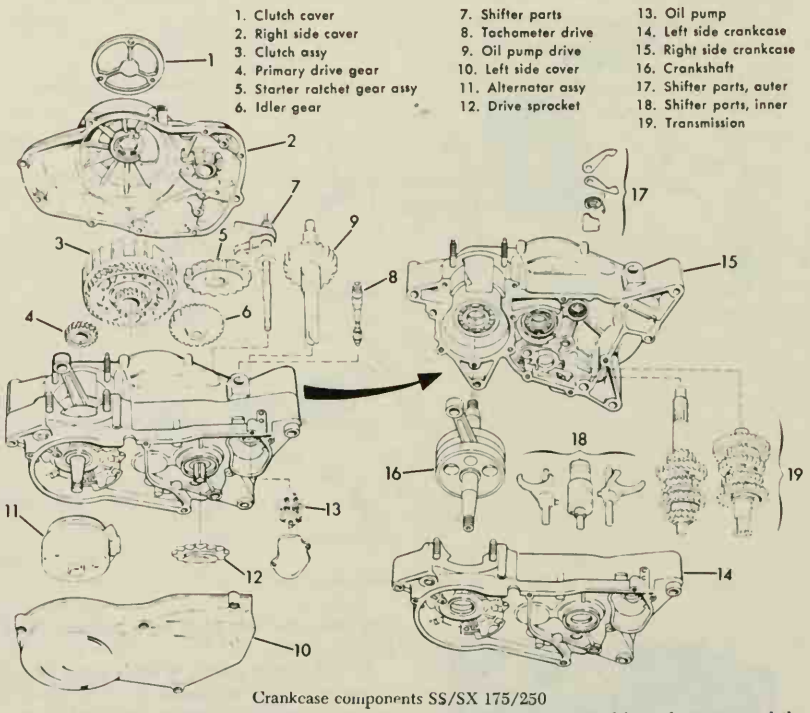
6. Slip the shaft thrust washer onto the shaft, then manipulate the starter shaft to

Starter assembly, B Models and 165

make sure its motion is smooth and positive.

7. Continue the assembly process in the reverse order of disassembly.

Disassembly



1. Drain the oil from the crankcase.
2. Remove the right crankcase cover.
3. Remove the ratchet gear and the washers located on either side of the gear, from the right crankcase.
4. Loosen the kick-starter lever pinch-bolt.
5. Holding the starter ratchet with one hand to prevent it from springing loose, rotate the kick-starter lever down until the ratchet is free of the release plate. Remove the ratchet and the spring from the kick-starter shaft.
6. Remove the kick-starter lever from the kick-starter shaft, then remove the shaft from the right crankcase cover.
7. Bend back the tabs of the lockplate and remove the two bolts securing the release plate to the right crankcase cover. Note the direction that the bend ends of the release plate are facing so that the plate can be installed in the same direction. Remove the spacer and the stop plate from beneath the release plate in the crankcase cover.

Inspection

1. Inspect the condition of the teeth on the starter ratchet and the ratchet gear. If the teeth are worn to a point where they will allow the gears to rotate in either direction, both components should be replaced.
2. If the return spring is broken or has deformed ends it should be replaced.
3. Inspect the lips of the oil seal in the right crankcase cover. If the lips are nicked, or otherwise deformed, the seal should be replaced.

Assembly

1. Install the stop plate, spacer, release plate, and lockplate onto the right crankcase cover with two bolts. Bend the tabs on the lockplate up against the flats on the heads of the bolts. If the tabs are fatigued the lockplate should be replaced.
2. Install the shaft into the right crankcase cover. Grease the lips of the oil seal in the cover before installing the shaft through it. Install the return spring on the shaft with the larger hooked end facing the right crankcase cover. Hook the end of the spring on the projection in the crankcase cover.
3. Install the ratchet on the shaft until the splines mesh, then hook the end of the return spring onto the projection on the ratchet.
4. Temporarily install the kick-starter lever on the shaft. Using the lever rotate the shaft while pushing the ratchet in on the shaft so that it catches under the release plate.
5. Remove the kick-starter lever and position it in the correct position. Install and tighten the kick-lever pinch-bolt.
6. Install the washer, ratchet gear, and another washer onto the end of the kick-starter shaft, then install the right crankcase cover.

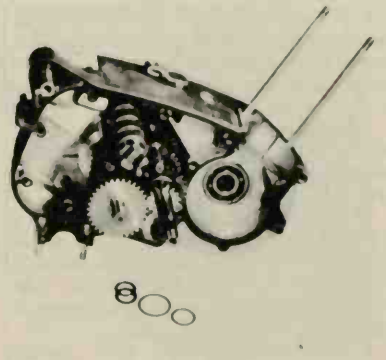
DISASSEMBLY

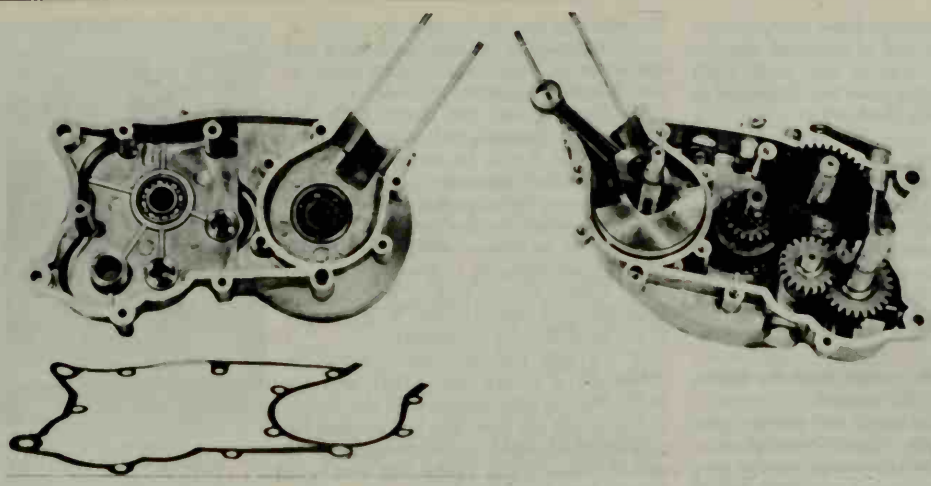
Models M-50 and M-65



1. Remove the engine from the frame as described in the engine "Removal and Installation" section, and disassemble the top end as described in the "Cylinder and Piston" section.
2. Remove the left side cover assembly as described in the "Starter" section.
3. Remove the magneto-generator assembly as described in the "Magneto-Generator" section.
4. Using Puller Tool (H-D part no. 97292-61), or a suitable substitute, pull the drive sprocket free. A gear puller may be used if care is taken not to damage the sprocket teeth. Remove the woodruff key.
5. Remove the drive pinion gear as described in the "Clutch" section.
6. Remove the crankcase studs which secure the right and left crankcase halves together.
7. Separate the crankcase halves with Crankcase Disassembly Tool (H-D part no. 97326-65), or a suitable substitute, while tapping on the cases with a soft mallet to make sure that they separate evenly. The tool mounts on the magneto's seat and presses on the crankshaft.
8. Bushings and bearings may be pressed out if worn, cracked, rough in motion, or otherw se damaged.
9. Remove the clutch actuating lever, if worn or damaged, by removing the shaft lockscrew (Model M-65 only) and then pulling the lever straight out.
10. Remove the crankshaft assembly from the crankcase.

M-125, M-100, X-90, Z-90, SR-100, and SX/TX 125 Models

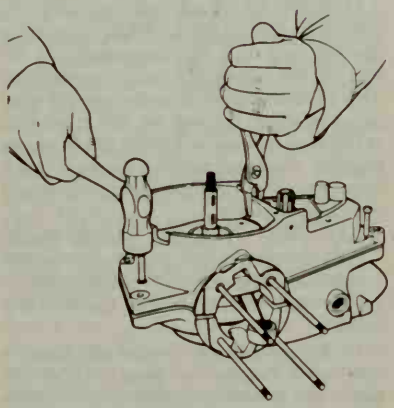
1. Remove the right side cover and clutch assembly as described in the "Clutch" section, and disassemble the top end as described in the "Cylinder and Piston" section.
2. Remove the shifter pawl carrier as described in the "Transmission" section.
3. Remove the magneto generator as described in the "Magneto-Generator" section.



Right Crankcase and Parts, M-125

Left Crankcase and Parts, M-100

The separated crankcase halves.



4. Using a suitable gear puller remove the drive sprocket. Remove the woodruff key.

5. Remove the drive pinion nut and pinion as described in the "Clutch" section.

6. Remove the crankcase studs which secure the crankcase halves together, then use Crankcase Disassembling Tool (H-D part no. 97347-68P), or a suitable substitute, while tapping the cases with a soft mallet to separate the crankcase halves. The tool mounts on the left crankcase pad and presses on both the crankshaft and countershaft.

7. Bushings and bearings may be pressed out if worn, cracked, rough in motion, or otherwise damaged. Blind bearings may be pulled free with Snap-On Puller (H-D part no. CG-40A) or a suitable substitute.

8. Continue as described in steps 9 and 10 in the previous section.

Separating the crankcase halves.

S and B Models

1. Remove the engine from the frame as described in the engine "Removal and Installation" section, and disassemble the top end as described in the "Cylinder and Piston" section.

2. Remove the generator (Model 165) as described in the "Generator" section, or the magneto-generator (Hummer, Super-10, etc.) as described in the "Magneto-Generator" section.

3. Remove the transmission mainshaft sprocket and the outer gear shifter indicator arm as described in the "Transmission" section.

4. Remove the clutch cover, drain the transmission oil, and remove the engine sprocket, primary chain, and clutch assembly as described in the "Clutch" section.

5. Remove the starter assembly as described in the "Starter" section.

6. Remove the oil seal screws and star washers, pry the oil seal from the crankcase side, and remove and discard the gasket.

7. Remove all the crankcase securing screws.

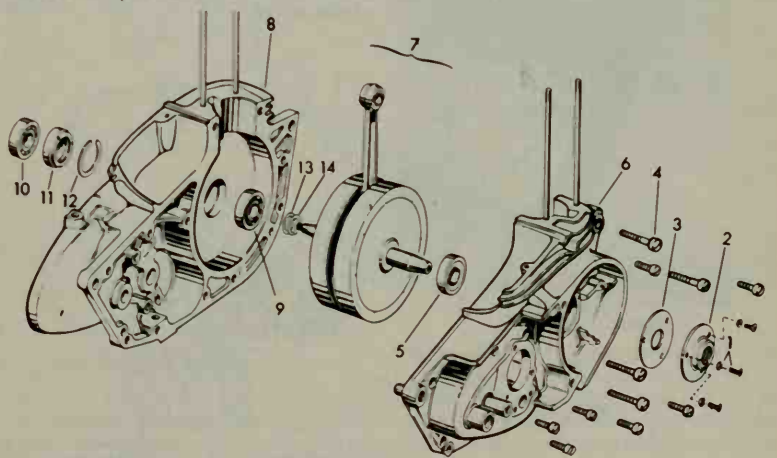
8. Separate the crankcase halves by inserting two engine-frame mounting screws as depicted, then alternately strike each screw with a soft mallet while supporting the crankcase with pliers. Apply heat with a blow torch to the cases around the magneto-generator or generator shaft, and around the locating dowel pins if the cases are difficult to separate.

9. If the crankshaft bearing remains in the case, it may be drifted out at this time with a suitably sized drift.

10. Remove the transmission as described in the "Transmission" section.

11. Remove the crankshaft assembly by holding the case with the shaft down and tapping the front of the case on a block of wood until the crankshaft assembly is loose. Apply heat with a blow torch around the sprocket shaft bearing if the flywheel assembly is reluctant to leave the case, but avoid placing direct heat on the bearing.

12. Remove the shaft bearings. If the bearings will not come free easily, then a puller bar must be fabricated for use with Wedge Puller (H-D part no. 95637-46) or a suitable substitute. You'll need the following items:



a. A piece of flat stock ½ in. thick and 1½ x 4 in. for the puller bar with 7/16 in. wide by 1 in. deep slots at the edges.

b. A puller screw from a Harley-Davidson puller or one with ½ x 18 thread.

c. A pair of 4½ in. long cap screws with ⅜ x 16 thread.

d. A ½ in. hex nut.

Secure the shaft in a copper or wood-jawed vise and use the puller to remove the bearing, then invert the crankshaft and

pull the other bearing. Place the ½ in. hex nut between the end of the shaft and the puller screw to protect the shaft while pulling the bearing from the generator or magneto-generator shaft.

13. Drift the sprocket shaft inner and outer bearings free of the case with a suitably sized drift. The oil seal and retainer will come out with the bearings. There are two spacing shims between the inner bearing and the flywheel on 1964 models and one shim on 1965 models. Apply heat with a blow torch to the case around the outer bearings if they are difficult to remove.

SS/SX 175/250

1. Remove the engine from the frame, and disassemble the top end.

2. Remove the clutch and primary gear as described in the "Clutch" section.

3. Remove the kick-starter ratchet gear and the washers located on either side of the gear. These should be laying loose in the right crankcase but may be on the end of the kick-starter shaft.

4. Remove the gear shift lever from the left-side of the engine. Pull the shift shaft and the oil pump drive shaft from the right crankcase.

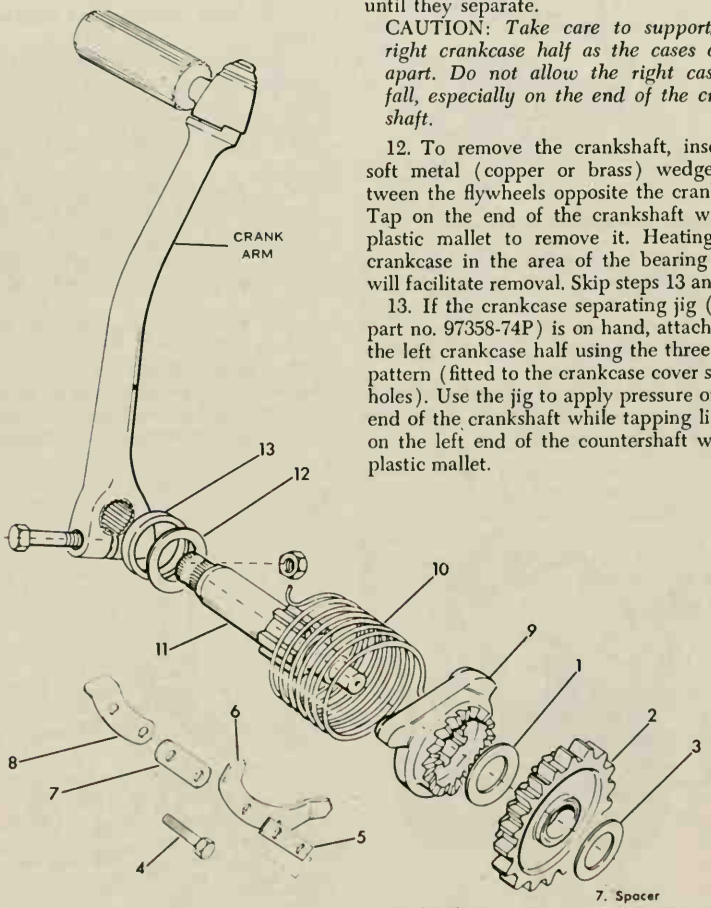
5. If desired the tachometer drive can be removed from the right crankcase after the retaining clamp is removed.

6. Remove the left crankcase cover and alternator as described in "Alternator" in the "Electrical Systems" section.

7. Remove the two bolts from the countershaft sprocket and rotate the lockplate so that it can be removed. Remove the countershaft sprocket.

8. Remove the oil pump as described in the "Lubrication System" section.

9. Using an impact driver, remove the 13 crankcase securing screws from the left side. These screws should be loosened gradually and evenly in an "X" pattern so as not to distort the crankcases.



10. To split the cases and remove the crankshaft a special tool (H-D part no. 97358-74P) is recommended. If this tool is not available the cases can be split and the crankshaft removed by following Steps 11 and 12 below. If this special tool is on hand skip to Step 13 below.

11. Hold the crankcases up with the right side facing down. While supporting the left case half, tap alternately on the end of the crankshaft and countershaft with a plastic mallet. Extreme caution must be used when tapping on the crankshaft as too hard of blow will pinch the flywheels together. Continue tapping the cases apart being sure that they are separating evenly until they separate.

CAUTION: *Take care to support the right crankcase half as the cases come apart. Do not allow the right case to fall, especially on the end of the crankshaft.*

12. To remove the crankshaft, insert a soft metal (copper or brass) wedge between the flywheels opposite the crankpin. Tap on the end of the crankshaft with a plastic mallet to remove it. Heating the crankcase in the area of the bearing boss will facilitate removal. Skip steps 13 and 14.

13. If the crankcase separating jig (H-D part no. 97358-74P) is on hand, attach it to the left crankcase half using the three hole pattern (fitted to the crankcase cover screw holes). Use the jig to apply pressure on the end of the crankshaft while tapping lightly on the left end of the countershaft with a plastic mallet.

Removing the crankshaft

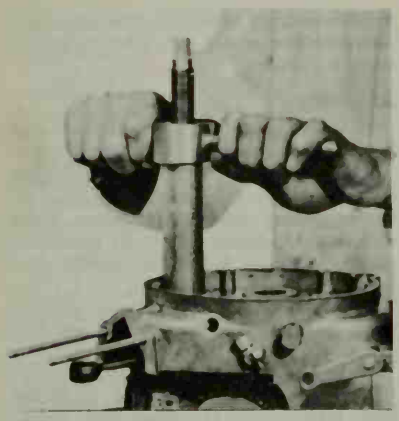
14. To remove the crankshaft, mount the crankcases separating jig to the right crankcase using the four hole pattern. Use the tool to push the crankshaft out of the right main bearing.

15. Remove the transmission mainshaft, countershaft, and shifter components from the right crankcase as described in the "Transmission" section.

16. Bearings and seals can be inspected in place in the cases. If damaged, the seals can be pried out, however, care must be taken to avoid scoring the seal seats. When removing bearings, gentle heat applied to the cases in the area of the bearing will make removal easier. Do not heat the bearing itself.

ASSEMBLY

Models M-50 and M-65



1. Assembly is in the reverse order of disassembly.

2. Use Crankshaft Assembling Tool (H-D part no. 97342-65P), or a suitable substitute, to pull the right crankshaft assembly into the right case ball bearing.

3. Assemble the transmission components as described in the "Transmission" section.

4. Install the left crankcase half on the crankshaft using the same tool as in step two, taking care not to damage the oil seal.

5. Measure the crankshaft end-play between the two main bearings with a dial indicator by shifting the crankshaft all the

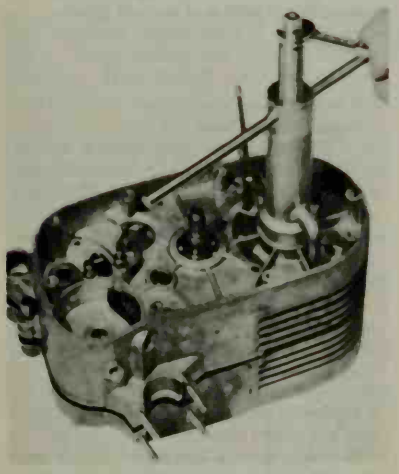
way to one side then shifting it all the way to the other side while positioning the indicator in such a way as to allow the plunger to measure the distance the crankshaft moves. Add more or less shims to the right crankshaft until play is within 0.004–0.008 in.



6. Complete assembly in the reverse order of disassembly.

M-125, M-100, X-90, Z-90, SR-100, and SX/TX 125 Models

1. Assembly is in the reverse order of disassembly.

2. Assemble the transmission components as directed in the "Transmission" section, taking care to remove the shifter cam stop before assembling the cases.

3. Install the left case over the left crankshaft using Crankshaft Assembling Tool (H-D part no. 97342-65P) or a suitable substitute, taking care not to damage any oil seals while pulling the shaft into the ball bearing.

Assembling the right crankcase.

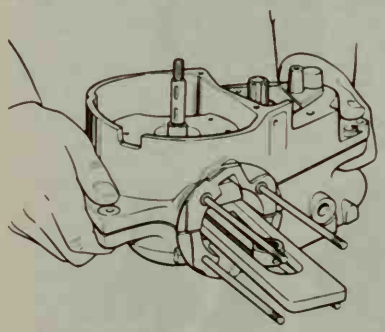
4. Using Crankshaft Assembling Tool (H-D part no. 96110-68P) or a suitable substitute, assemble the right shaft into the right bearing.

5. Measure the crankshaft end-play between the two main bearings with a dial indicator by shifting the crankshaft all the way to one side then shifting it all the way to the other while positioning the indicator in such a way as to measure the distance the crankshaft moves. Add more or less shims to the left shaft until play is within 0.002–0.004 in. Crankshaft Assembling Tool (H-D part no. 96110-68P) can be used to shift the crankshaft from left to right.

6. Complete assembly in the reverse order of disassembly.

S and B Models

1. Support the flywheel assembly on two 5 in. blocks and lightly press the bearings onto their respective shafts until they bottom. The 1964 and earlier models have two spacers between the sprocket shaft bearing and the flywheel. Use a piece of pipe ¾ in. in diameter and 4½ in. long as a sleeve for pressing the bearing in place.



2. With the left crankcase clutch side up on a workbench, install the oil seal spring ring, lubricate the oil seal and retainer with engine oil, and drift or press it into place with the slotted side facing in.

3. Invert the case and assemble the transmission as directed in the "Transmission" section.

4. Place the flywheel tapered spacer which comes in the Tool Set around the lower connecting rod bearing to prevent the flywheels from closing during installation. Anything which will keep the flywheels aligned, and which will fit snugly between the two, may be substituted.

5. Assemble the flywheel assembly in the left case. The sprocket shaft bearing should seat against the oil seal retaining ring. Apply heat to the case around the bearing bore with a blow torch if the bearing will not readily slip into the case. Take care not to damage the oil seal.

6. Apply a suitable sealer to the crankcase mating surfaces and carefully assemble the right case to the left case, making sure that the inner gear indicator arm and the gear shifter ratchet yoke are properly engaged. Apply heat to the dowel pin holes, and around the bearing bore if the bearing will not readily slip into the case. Test for a positive engagement of the indicator arm then secure the crankcase screws.

Assembling the crankcase halves.

7. Assemble the transmission mainshaft oil seal, drive sprocket, and outer gear indicator arm as described in the "Transmission" section.

8. Apply a suitable gasket sealer to a new oil seal gasket and assemble it and the oil seal to the right case.

9. Remove the flywheel tapered spacer.

10. Install the generator on the Model 165 as described in the "Generator" section.

11. Install the magneto-generator on the B Models as described in the "Magneto-Generator" section.

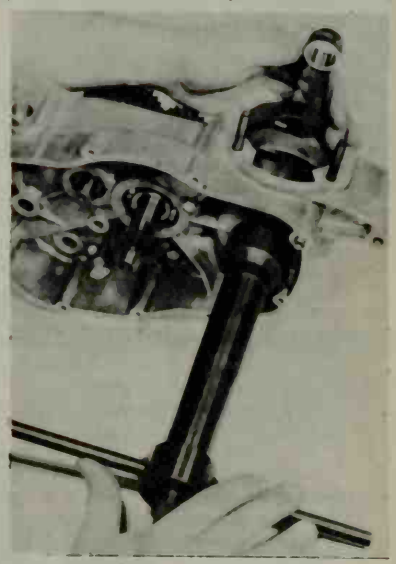
12. Place the engine clutch side up and install the starter assembly as described in the "starter" section.

13. Install the countershaft sprocket, primary chain, and clutch assembly as described in the "Clutch" section.

14. Install the top end as described in the "Cylinder and Piston" section.

15. Install the clutch and magneto side covers, and install the engine in the frame as described in the "Engine Removal and Installation" section.

16. Adjust the ignition timing as described in the "Tune-Up" section.

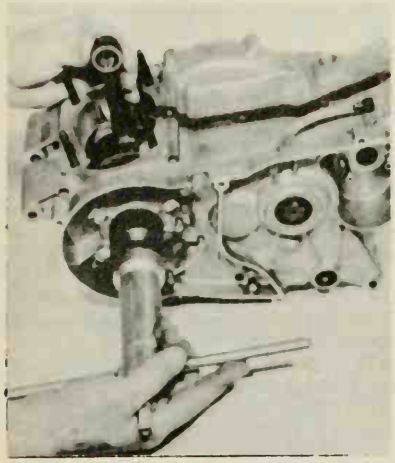


SS/SX 175/250

1. Install all bearings and oil seals into the case halves. Install the transmission as described in the "Transmission" section.

2. Install the crankshaft into the right case half using the special tool (H-D part no. 97297-61PA) and spacer (H-D part no. 96111-74) as shown.

3. Apply a light coat of liquid gasket compound to the right crankcase and install the crankcase gasket.



4. Install the left crankcase into position over the end of the crankshaft and countershaft. Install the special tool (H-D part no. 96110-68P) and spacer (H-D part no. 96111-74) on the left end of the crankshaft. Using the tool pull the cases together evenly, tap the rear of the cases with a plastic mallet if necessary.

Installing the crankshaft

5. Measure the crankshaft end-play with a dial gauge by shifting the crankshaft all the way to one side then shifting it all the way to the other side while positioning the gauge in such a way as to allow the plunger to measure the distance the crankshaft moves. Add more or less shims to the left side of the crankshaft until the play is within 0.002–0.004 in. (0.05–0.10 mm).

6. Complete assembly in the reverse order of disassembly.

MODELS M-50 AND M-65

Removal and Installation

1. Remove the engine from the frame as described in the engine "Removal and Installation" section.
2. Separate the crankcase halves as described in the "Crankcases" section.
3. Installation is in the reverse order of removal.

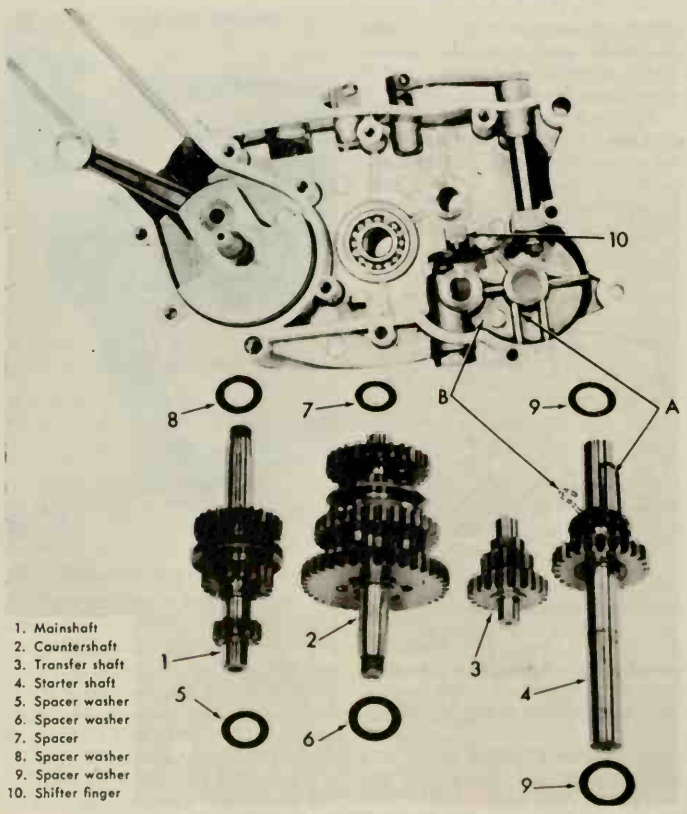
Preliminary Inspection

1. Inspect the gear teeth for a worn, damaged, pitted, or scored condition.
2. Inspect the gear dogs for a worn or damaged condition.
3. Inspect the mainshaft, countershaft, transfer shaft, and starter shaft for a pitted, grooved, warped, or worn condition especially at the bearing surfaces.
4. Inspect the shifter finger for a grooved, damaged, warped, or worn condition.
5. Once the necessary repairs have been determined, proceed to disassemble those assemblies which are to be repaired. Gears should be replaced in sets because when a countershaft gear is damaged, all those gears which have been in contact with it have been affected and, therefore, require attention.

Disassembly

1. Place the transmission in third gear, then remove the transfer shaft, countershaft, and spacer washer.
2. Remove the countershaft lock and thrust washers, and the first, second, and third gears from the countershaft.
3. Remove the mainshaft assembly from the crankcase. Remove the mainshaft spacer washer, pull third gear from the shaft with a suitable gear puller, and slip the mainshaft second gear from the shaft.
4. Remove the shift lever locating guide, gasket, lever ball, and ball spring.
5. Remove the shifter shaft nut, lockwasher, spacer, lever, spacer, and O-ring from the shaft, and pull the shaft from the crankcase. Remove the shifter finger from the shifter lever.

Inspection



1. Clean all parts in a suitable solvent and blow them dry.
2. Inspect all parts for a worn or damaged condition and replace them as necessary. Don't reuse any part if its life expectancy is dubious.

Assembly

1. Assembly is basically the reverse order of disassembly.
2. Secure first gear on the countershaft with the spacer and lockring, then mount the remaining countershaft gears. Make sure that the smaller side of the third gear clutch holes are facing the second gear lugs.
3. Slip the mainshaft second gear in place on the shaft then press first gear into place.
4. Assemble the mainshaft and countershaft assemblies to the right crankcase half, taking care to engage the shifter finger and the mainshaft second gear collar into the countershaft second gear groove.
5. Engage the starter clutch spring in the crankcase recess as shown in the Transmission Gear Shaft Assemblies illustration. On models before engine no. 65M3539, engage the spring at "A," and for later models engage the spring at "B."
6. Replace the spacer washers in their original locations if no new gear or shaft parts have been incorporated. Where new parts are used determine the correct spacer thickness in the following manner:
   a. Install the mainshaft with a 0.6 mm washer in the right crankcase half.
   b. Install the countershaft with an 0.8 mm washer in the right crankcase half.
   c. Manipulate the shifter lever so the transmission is in third gear, and insert a 0.004 in. thickness gauge between the countershaft second and third gears to determine whether there is at least that much clearance between them.
   d. Shift the transmission and repeat the above measuring sequence on the countershaft first and second gears.
   e. Check the clearance between the mainshaft first and second gears, with the transmission in first gear, and use the appropriate size washer to bring the clearance to at least 0.004 in.
   f. Assemble the appropriate spacer washers to the mainshaft, countershaft, and starter shaft to bring the clearance to within 0.004–0.006 in. for the mainshaft, and to within 0.004–0.008 in. for the other two shafts. This is also a good time to check the crankshaft end-play.
   g. Assemble the two crankcase halves with all the components installed, then check the various shaft end-plays with a dial indicator by shifting the shaft to one side and then to the other side. A soft mallet may be necessary to stimulate the shafts into motion.
   h. Seperate the crankcase halves and install the appropriate size spacer to correct the end-play, then repeat step "g."
7. Complete the assembly process in the reverse order of disassembly and replenish the oil supply.

2. Turn the knurled adjuster nuts counterclockwise to reduce the cable slack, taking care not to make the cable too taut, then secure the locknuts.

3. If the adjuster runs out of thread space or if the cable clamps have been removed, proceed in the following manner:

a. Loosen the upper and lower clamping block setscrews.

b. Place the transmission hand control in the neutral position.

c. Adjust the cable adjusters so there are several threads left betweeen the locknut and cable coil.

d. Shift the shift lever position to make sure the transmission is in neutral. Moving the lever toward the left will place the transmission in first. One step to the right should be neutral and the rear wheel should rotate freely with the clutch in or out.

e. Secure the upper and then the lower cable clamping block setscrews while pulling on the cable to provide the necessary tension. The upper cable housing must be seated on the crankcase anchor.

4. Adjust the cable as described in steps one and two. When correctly adjusted, the engine will run while the hand indicator is on neutral without slipping into first or second gear.

5. Install the cable in the following manner:

a. Loosen the housing clamp screw located near the control cables and slip the handgrip off the handlebar.

b. Slip the cables through the housing slots.

c. Inspect all parts for a worn or damaged condition and replace them as necessary. Always grease the cable or lubricate it with engine oil or a chain lubricating compound before replacing it.

d. Replace the cable in the reverse order of removal.

Footshift Linkage Adjustment and Repair

1. Remove the cotter pin, washer, and link rod from the hole in the shifter lever.

2. Place the transmission in second gear by moving the shift lever clockwise to third gear and then back one step to second gear.

3. Rotate the link rod in the threaded ball joint until it is aligned so it can be inserted in the lever hole. Secure the rod locknut and secure the link arm with the washer and a new (if possible) cotter pin.

4. Remove the cover screw, acorn nut, washer, cover, pawl spring, and pawls.

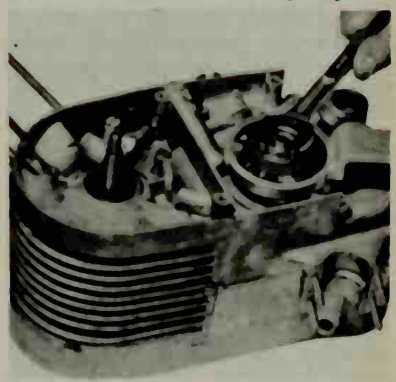
5. Remove the shifter lever nut, washer, shifter lever, spring cups, springs, and ratchet.

6. Clean all parts in a suitable solvent then blow them dry.

7. Replace all worn or damaged parts as necessary.

8. Liberally grease all pawl and ratchet parts before assembly which is the reverse of disassembly.

MODELS M-100 AND M-125



Drive Sprocket

REMOVAL

1. Remove the sprocket cover screws and cover.

2. Secure the sprocket with Transmission Sprocket Wrench (H-D part no. 97305-68P, for 14 tooth sprockets, and no. 97297-68P for 15 tooth sprockets), or a suitable substitute, then remove the sprocket nut.

3. Remove the nut lock and pull the sprocket free with a suitable gear puller.

Removing the drive sprocket.

INSPECTION

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect all parts for a worn or damaged condition and replace them as necessary.

INSTALLATION

1. Place the sprocket on its shaft with the hub facing the crankcase.

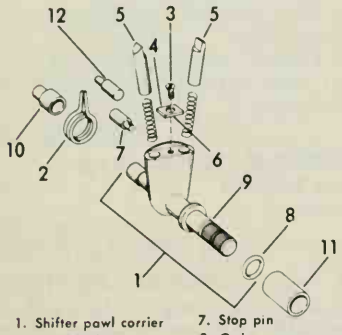
2. Secure the lock and nut and bend the locktab against the flat side of the nut.

3. Replace the cover and secure it with the cover screws.

Shifter Pawl Carrier

DISASSEMBLY

1. Remove the pawl carrier assembly from the crankcase, and remove the return spring from the rear of the shifter carrier.



2. Check the shifter pawl movement. If the movement is awkward or if any of the components are visibly damaged, the as-

sembly must be disassembled by removing the spring plate screw, pawl spring retainer plate, pawls, pawl springs, and the shifter lever stop pin.

INSPECTION

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect the shifter pawls and springs for a worn, grooved, cracked, or damaged condition, and replace them as necessary. Replace the pawl springs as a set if either are less than 1.5 in. long.

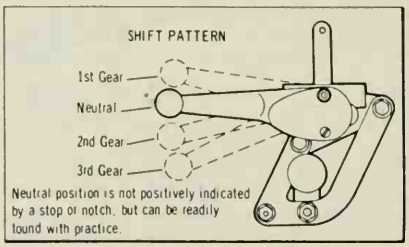
3. Insert the pawls and springs in the carrier holes so the flat portions face each other, then check their action for a smooth, free operation.

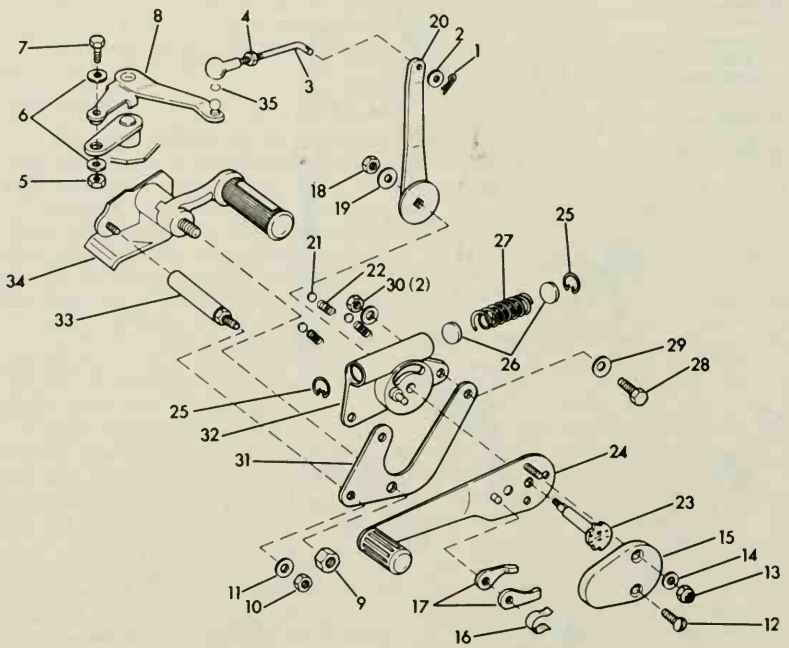
4. The crankcases must be split if the shifter carrier bushing is in need of replacement. The bushing is a press fit which may be removed with a suitable shouldered drift from the inside out, and replaced by pressing in from the outside. The new bushing will not require reaming.

5. Inspect the carrier for a worn or damaged condition and replace it as necessary.

6. Inspect the rubber O-ring for a worn, cracked, or damaged condition and replace it if necessary. It is a good practice to replace such items whenever possible.



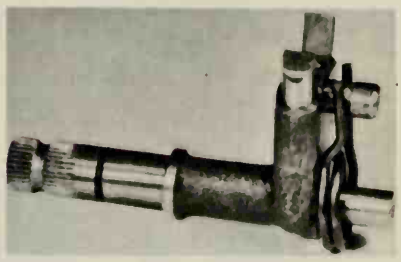
7. Inspect the cover bushing for a worn or damaged condition and replace it if necessary by pressing with a suitable shouldered drift from the inside out. When installing the new bushing, make sure the chamfered side is facing in. Press the bushing from the outside in until flush with the bushing boss. Reaming this bushing will not be necessary.



ASSEMBLY

1. Slip the pawl springs into the pawls, then install the pawls into the carrier so the flat portions are facing each other.

2. Press down on the pawls, slip the pawl spring retainer plate down against the carrier, insert the stop pin with its hole facing upward, and secure the assembly with the screw which goes through the carrier and into the stop pin.



3. Slip the return spring on the carrier with the offset portion facing the crankcase and the stop pin between the spring arms.

Removal and Installation

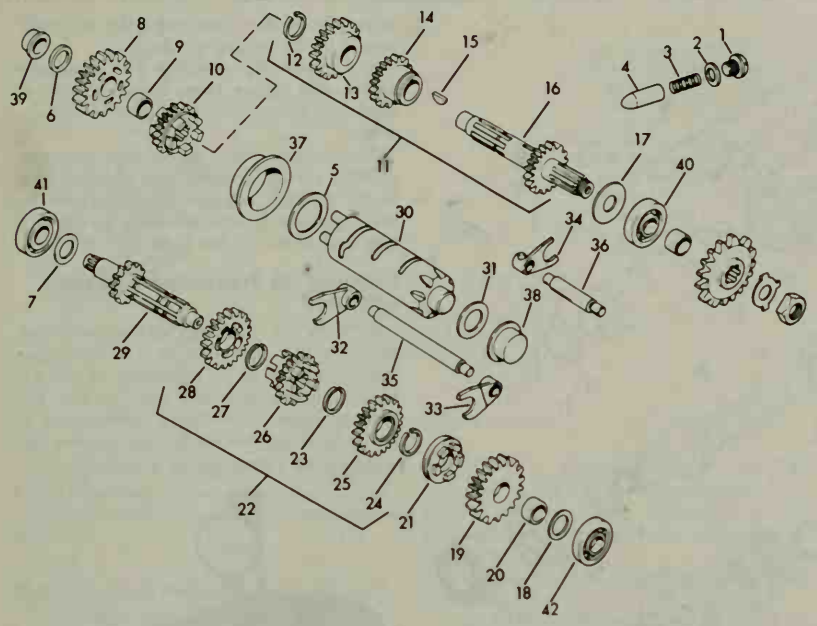
1. Remove the engine from the frame as described in the engine "Removal and Installation" section.

2. Remove the magneto-generator as described in the "Magneto-Generator" section.

3. Disassemble the shifter cam stop parts 1–4 (as listed in the exploded view illustration) from the crankcase.

4. Separate the crankcase halves as described in the "Crankcases" section.

5. Replacement is in the reverse order of removal.



Disassembly

MODEL M-100, SR-100, SX/TX 125

1. Place the left crankcase on the work bench with the gear assemblies pointing up.

2. Remove the variable-thickness shifter cam, countershaft, and mainshaft spacer washers.

3. Hold the countershaft gears together while tapping on the countershaft splined end with a soft mallet, lift all three assem-

4. Disassemble the countershaft assembly in the following manner:

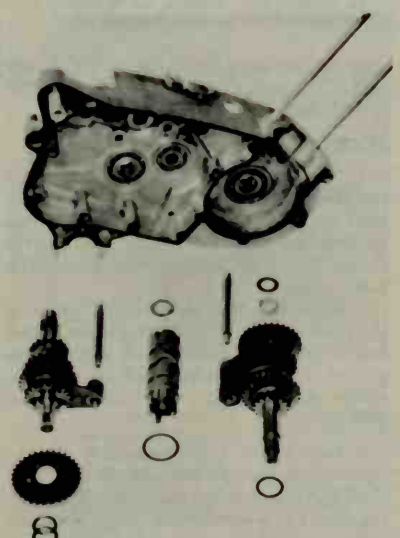
a. Slip the countershaft first gear and bushing free from the shaft.

b. Remove the countershaft fourth gear from the splined shaft.

c. Remove the lockring, second gear, third gear—with the aid of a suitable gear puller, and the countershaft key (if replacement is necessary).

5. Disassemble the mainshaft assembly in the following manner:

a. Remove the mainshaft fifth gear, bushing, and the fifth gear shifter clutch.



b. Remove the lockring, third gear, second gear, the fourth gear lockring, and fourth gear.

6. Remove the shifter cam, shifter forks, and shifter fork shafts.

MODEL M-125, X-90, Z-90

1. Place the right crankcase half on a work bench so the gear assemblies are pointing up.

2. Remove the variable-thickness shifter cam, countershaft, and mainshaft spacer washers.

Transmission gear shaft assemblies.

3. Remove the shifter cam and countershaft assemblies, and the mainshaft fourth and third gears all at once. Take careful note of the shifter fork positions in relation to the sliding gears for replacement purposes.

4. Remove the mainshaft assembly by tapping on the end of the shaft with a soft mallet.

5. Remove the variable-thickness shifter cam, countershaft, and mainshaft spacer washers.

6. Remove the countershaft first gear, second gear, lockwasher, and third gear.

7. Remove the shifter fork cotter pins, pins, forks, and cam. Take note of the position of the countershaft fork to the mainshaft fork and the locations of the shifter fork pins in the cam grooves for reassembly purposes.

8. Remove the mainshaft lockring and second gear.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect all parts for a worn, scored, warped, or otherwise damaged condition and replace them as necessary.

3. Inspect the gear dogs, dog slots, and shifter fork grooves for a chipped or damaged condition and replace them as necessary.

4. Pay special attention to the gear teeth. If one gear is damaged and is to be replaced, it is a good practice to replace the other teeth which mesh with it.

5. Inspect the shifter cam for grooved or worn slots at the various gear positions.

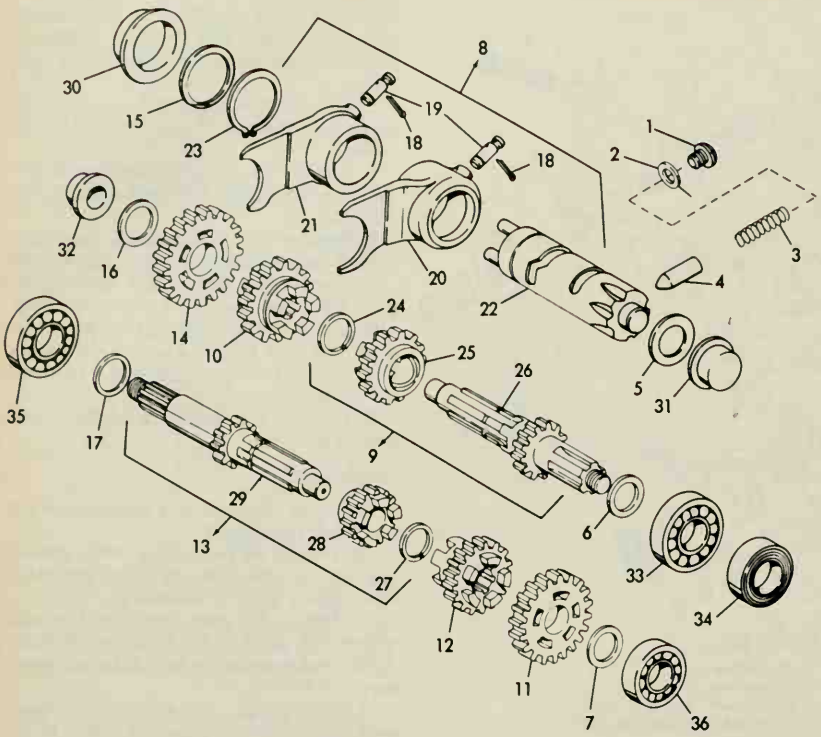
6. Inspect the shifter forks and fork pins for a warped or damaged condition, and for grooves worn into the fork fingers, then replace them as necessary.

7. Inspect the shifter cam stop plunger and spring for rough motion or a worn or damaged condition, especially on the plunger face, and replace them as necessary. The spring must be replaced if shorter than 1.535 in.

8. Inspect the bushings and bearings for excessive side or radial (up-and-down) play, pitting, damage, or rough motion. and replace them as necessary. Do not remove any bearing or bushing which doesn't require replacement.

9. Press the mainshaft and countershaft bearings out from the outside-in. The mainshaft left side bearing is blind and must be pulled with Bearing Puller (H-D part no. CG-40A) or a suitable bearing extractor.

10. Remove the left-side sprocket gear oil seal, then press the bearing free from the outside-in.



11. Ream the left and right shifter bushings after installation, using Large Bushing Reamer (H-D part no. 97322-61P) and Small Bushing Reamer (H-D part no. 97318-61P) or suitable substitutes.

Assembly

1. Press in all bearings until they are firmly seated.

2. Use the same number and size of spacers as were removed. Any corrections will have to be made after the end-play has been determined.

3. Make the preliminary assembly without the flywheel assembly so that the most accurate mainshaft, countershaft, and shifter camshaft end-plays can be achieved.

MODEL M-100, SR-100, SX/TX 125

1. Assemble the mainshaft group, then insert it and the left-side spacer washer into the left crankcase half.

2. Assemble the countershaft second and third gears to the shaft, then insert the shaft through the left side spacer washer and into the left crankcase half, tapping gently with a soft mallet if necessary. Assemble the countershaft fourth and first gears.

3. Position the left-side shifter cam spacer then assemble the shifter cam to the left crankcase half.

4. Assemble the fifth gear shifter fork to the shifter clutch so the cam pin on the back of the fork pivot section rides in the lower, left-side cam slot. Assemble the second gearshifter fork into the mainshaft second gear groove so the cam pin rides in the upper, right-side slot in the shifter cam.

5. Install the shifter fork shaft, taking care not to disturb the positions of the forks.

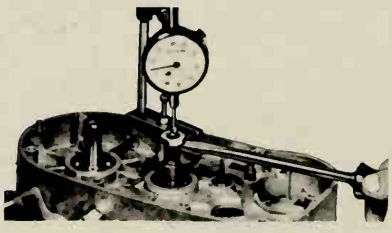
6. Install the countershaft shifter fork into the groove in the countershaft fourth gear so the cam pin rides in the middle slot in the shifter cam, and install the shifter fork shaft.

MODEL M-125, X-90, Z-90

1. Slip the shifter forks in position on the shifter cam so the male fork is assembled into the female fork. Secure the forks in their respective grooves by inserting the shifter fork pins and securing them with cotter pins.

2. Assemble the countershaft gears to the shaft so the mainshaft third gear shifter fork engages the countershaft second gear groove, and the countershaft second gear shifter fork engages the mainshaft third gear groove.

3. Install the above assembly in the right crankcase half along with the mainshaft and countershaft assemblies and their respective spacer washers. Make sure that the flat face of the countershaft first gear is toward the countershaft second gear, and the flat face of the mainshaft fourth gear is facing the mainshaft third gear.



4. Place the appropriate spacer washer on the end of each of the three shafts, and rotate the shifter cam until the transmission is in the neutral position.

5. Temporarily assemble the crankcase halves and secure them together with at least two screws directly opposite one another.

6. Assemble the cam stop plunger, plunger spring, washer, and plunger plug so the plunger engages the middle of the three grooves located sideways on the cam stop end of the shifter cam.

Checking the Transmission Shafts End-Play

1. With the crankcase halves assembled, mount a dial indicator on one side, then shift the shaft to be measured to the extreme opposite side and then back to the extreme other side. Use a screwdriver to aid in shifting the shafts, but remove the screwdriver before taking a reading.

Checking the mainshaft end-play.

2. Disassemble the crankcase halves and install the appropriate size spacer washer on the shaft ends to bring the endplay to within the specified limits. Rather than just using one larger washer, use two slightly smaller ones to maintain the proper balance.

3. If the crankshaft assembly has been worked on, check the crankshaft end-play.

4. Reassemble the crankcases and recheck the end-play. Repeat the above operations until the end-play is correct. The shifter cam end-play should be within 0 008–0.012 in.; the countershaft end-play should be within 0.002–0.006 in., and the mainshaft end-play should be within 0.002–0.006 in. Consult the following chart for the appropriate size washer.

Drive Sprocket Removal and Installation

1. Remove the clutch release rod.

2. Bend back the mainshaft sprocket nut lockwasher ear from the mainshaft sprocket nut and oil seal, then remove the nut (which has a left-hand thread) and lockwasher.

3. Remove the mainshaft drive sprocket with a suitable gear puller.

4. Remove the main drive gear collar, oil seal screws, oil seal, and the oil seal gasket which should be replaced every time it is removed.

5. Clean all parts in a suitable solvent and blow them dry.

6. Inspect all the parts for a worn or damaged condition and replace them as necessary.

7. Assembly is in the reverse order of disassembly. The replacement gasket should be coated on both sides with a suitable gasket sealer before assembly.

Disassembly

1. Place the left crankcase on the work bench with the gear assemblies pointing up.

2. Remove the countershaft assembly and disassemble the countershaft gear thrust washer, sliding gear, and first gear.

3. Remove the mainshaft sliding gear then drift the shaft out of the left bearing with a suitable drift.

4. Slip the mainshaft into the main drive gear and check for excessive clearance, wear, or damage which would necessitate the removal of the gear. If necessary, tap the gear and its bearing free of the case with a soft mallet. The bearing and bushing need not be removed unless worn, damaged, or excessively loose in the case.

5. Inspect the left mainshaft bearing for excessive play, wear, damage, or rough motion before removing it. Remove the inner and outer spring rings and drift the bearing free with a suitable drift if replacement is necessary.

6. Remove the countershaft gear from the shaft with a suitable gear puller if replacement is necessary. The gear is a press fit on the shaft.

7. Drift the gear shifter shaft from the case with a suitable drift, pry the pawl retaining ring free from its groove in the shaft, and remove the shifter pawl spring and spring cover.

8. Disassemble the ratchet assembly in the following manner:

a. Remove the ratchet spring key, spring collars, spring, and the gear shifter ratchet.

b. Bend back the tabs on the ratchet bracket bolt lockwashers, remove the cap screws, and remove the gear shifter ratchet bracket and spring pin.

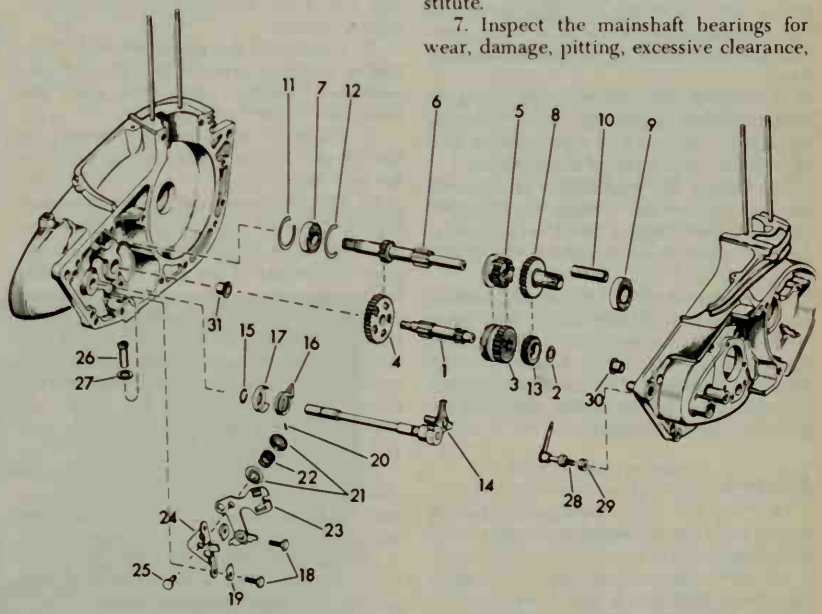
9. Inspect the ball retainer and retainer washer for a worn or damaged condition, loose fit in the case, or the ball remaining in the depressed condition when pressed down into the retainer. Drift them free with a suitable drift from their press fit position in the case if replacement is necessary.

10. Remove the inner arm of the gear indicator from the case with pliers if replacement is necessary.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect the mainshaft sprocket nut and oil seal and the inner oil seal for a worn, cracked, or otherwise damaged condition which might cause leaks, and replace them as necessary. The sprocket nut seal must be pried free.



3. Inspect all the gears for a worn, chipped, damaged, or excessively loose fit on their respective shafts and replace them as necessary.

4. Inspect the gear dogs and slots for wear or damage at the thrust points and replace the gears as necessary.

5. Inspect all points on which the bearings ride for excessive wear, pitting, grooving, or scoring, and replace them as necessary.

6. Inspect the fit of the main drive gear and its bushing for play in excess of 0.0025 in. and replace them if necessary by drifting them out with an appropriate size drift or by threading a tap into the bushing then drifting it free from the opposite side. Ream a new bushing with Reamer (H-D part no. 95924-48) or a suitable substitute.

or rough motion and replace them as necessary with a suitable drift.

8. Inspect the countershaft bushings for excessive play by measuring the shaft side-movement from the end opposite the bushing to be inspected. If the clearance is correct (0.0005–0.0015 in.) there will be 1/64–1/32 in. side-motion. When the motion exceeds these limits by 1/16 in. or more, the need for replacement is indicated. Replace the bushings in the following manner:

a. Drift the bushings out with a suitable drift.

b. Press in the new bushings, taking care to align the bushing shoulder oil slot which should be pointed upward.

c. Securely assemble the crankcase halves to check for proper alignment. It may be necessary to heat the cases around the dowel pin holes to make them come together.

d. Line-ream the bushings using Reamer (H-D part no. 95924-48) or a suitable substitute. Use the bushing opposite the one to be reamed as a guide, then switch and ream the other bushing. Continue to rotate the reamer clockwise while withdrawing it.

9. Inspect the pawl claws of the gear shifter shaft and the mating surfaces of the gear shifter ratchet for a worn or damaged condition which may cause sloppy gear changes, and replace them as necessary.

10. Replace the pawl retaining clip, and inspect the shifter pawl spring for a worn or damaged condition. Replace it as necessary. It is a good idea to replace this spring since, if it fails, the shift lever will not automatically return to a ready position and will have to be manipulated by hand.

11. Inspect the ratchet spring and gear shifter ratchet spring pin for a worn or damaged condition and replace them as a set if either is in need of replacement.

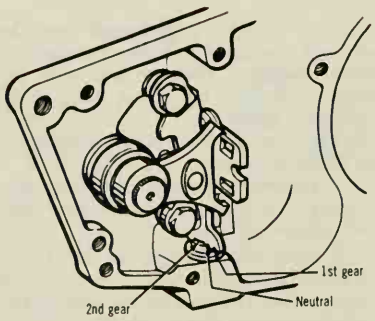
12. Inspect the gear shifter ratchet and ratchet bracket for a worn or damaged condition and replace them as necessary. Do not attempt to straighten out either part.

13. Inspect the ball retainer and washer as described in "Disassembly" step nine.

14. Inspect the tip of the gear indicator inner arm for a worn or damaged condition and replace it if its condition is questionable since failure of this part will immobilize the transmission.

Assembly

1. Place the left crankcase on a work bench with the transmission compartment facing upward.



2. Press the ball retainer and washer into the crankcase, if they have been removed, taking care to align the retainer slot with the crankcase joint face.

3. Assemble the gear shifter ratchet spring pin, ratchet bracket, ratchet, spring collar, spring, and spring key, in that order, then secure the bracket with the bracket bolt lockwashers and cap screws. Fold the tabs of the washers up and engage the ratchet teeth with the ball retainer.

4. Assemble the pawl retaining clip, shifter pawl spring cover, pawl spring, and the gear shifter shaft, taking care to install the spring on the shaft so the end of the spring is as far from the pawl as possible so the spring ends will properly engage the shifter bracket lug.

5. Slip the shaft and pawl assembly into the left case half so the pawl claws extend halfway over the ratchet plate. The ratchet plate should be able to be pushed far enough forward for the pawl to clear the plate in either of its extreme positions. Place the transmission in second gear before continuing.

6. Install the outer mainshaft bearing spring ring, then press the left-side mainshaft bearing into the case from within until seated against the spring ring. Install the inner bearing spring ring in its groove in the case.

Shifter mechanism in second gear.

7. Press the main drive gear bearing and the drive gear into position in the right crankcase.

8. Lightly oil the mainshaft with clean engine oil then press it into the left-side mainshaft bearing until flush with the outer face of the bearing.

9. Place the countershaft first gear on the left-side countershaft bushing with the flat side facing up.

10. Hold the mainshaft and countershaft sliding gears in mesh together, slide the mainshaft gear onto the mainshaft and engage the fingers of the gear shifter ratchet while maintaining the gears in the meshed position, then slip the countershaft through the countershaft sliding and first gears and into the left-side countershaft bushing. Assemble the countershaft third gear and the third gear thrust washer to the shaft.

11. Install the gear indicator inner arm and oil seal if it has not yet been done.

12. Lubricate the gears thoroughly with clean engine oil, then shift the gears several times to make sure the transmission will operate smoothly and accurately.

13. Complete the reassembly procedure in the reverse order of disassembly and replenish the transmission oil supply.

SS/SX 175/250

Removal and Installation

1. Remove the engine and split the crankcases as described in "Crankcase."

2. Remove the circlip from the end of shift fork shaft protruding through the right crankcase. Pry the two pawl arms away from the shift drum and remove them and the spring behind them.

3. Remove the retaining plate mounting screw and the retaining plate from the right crankcase. Pull the shift fork shafts and the shift forks. Remove the shift drum.

4. Using a plastic mallet tap the mainshaft and countershaft from the right crankcase. Tap the shafts so that they come out at the same time.

5. Installation is the reverse of removal. Note that both transmission shafts are installed together.

Disassembly

1. Remove each snap-ring and the gear below it until all of the gears are removed. On later SX-250 models the gears ride on needle bearings, with the exception of the countershaft first gear these needle bearings are uncaged with 25 needles in each of four gears. Take care not to loose the bearings.

2. When each component of the transmission is removed, it should be laid out so that it can be installed in the same location.

Assembly

1. Assembly is the reverse of disassembly.

2. When installing needle bearings in gear so equipped, use light grease to hold the bearings in place.

3. A special tool (H-D part no. 97361-74P) is available to install the transmission snap-rings. If this tool is not used take care not to distort the snap-rings.

4. Check side clearance of the gears in the neutral position. If the clearance exceeds 0.002–0.0024 in. (0.037–0.060 mm) install additional thrust washers until the clearance is brought into specifications.

5. Check the end-play with the gears in the neutral position. If excessive install thrust washers until correct.

Engine Removal and Installation

1. Disconnect the battery ground wire (−) and the spark plug lead, then remove the spark plug.

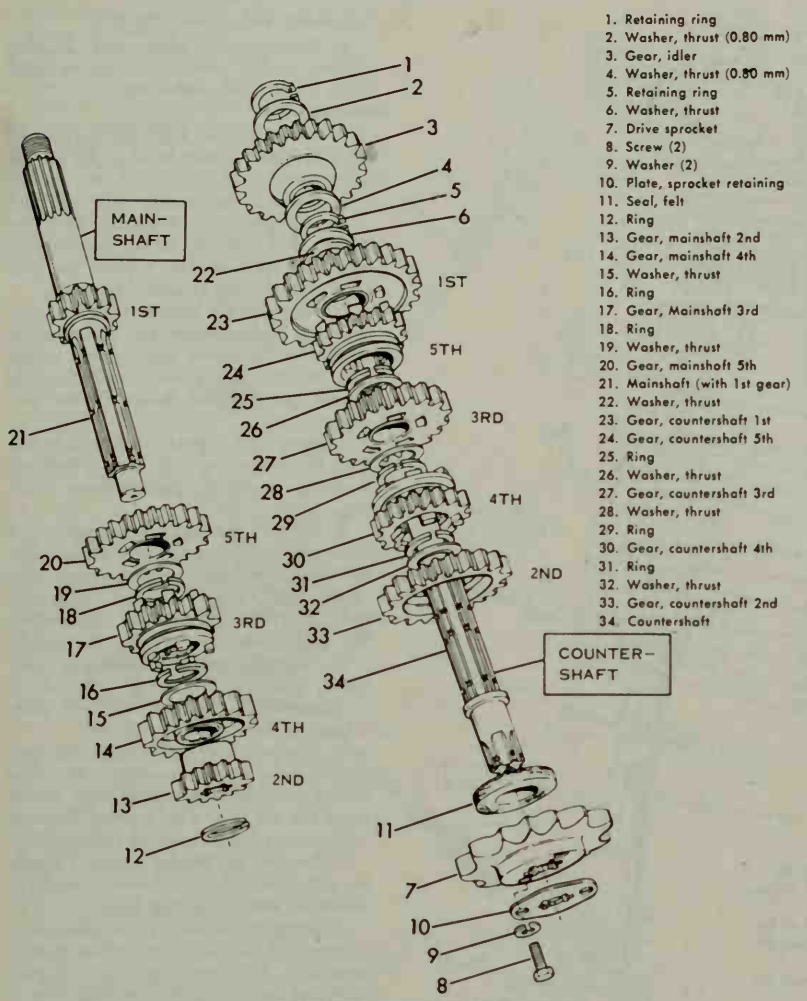
2. Close the petcock, remove the fuel line fitting at the carburetor, release the fuel tank hold-down spring, tilt the tank forward to unhook the front mounting, and remove the tank.

3. Unhook the footbrake lever-return spring and remove the left footrest.

4. Remove the left crankcase cover securing screws and the cover.

5. Disconnect the generator wires at the generator and pull them free from the frame compartment.

6. Disconnect and remove the drive chain.



7. Remove the upper mounting bolt nuts but do not remove the bolts.

8. Rotate the clutch release lever forward and disconnect the clutch cable.

9. Remove the contact breaker cover, disconnect the contact breaker leads, and pull the wires free of the case.

10. Remove the nuts and washers from the exhaust manifold clamp, remove the rear footrest and muffler support, and lift the entire exhaust assembly free.

11. Remove the intake manifold nuts, on early-model carburetors, plug up the in-

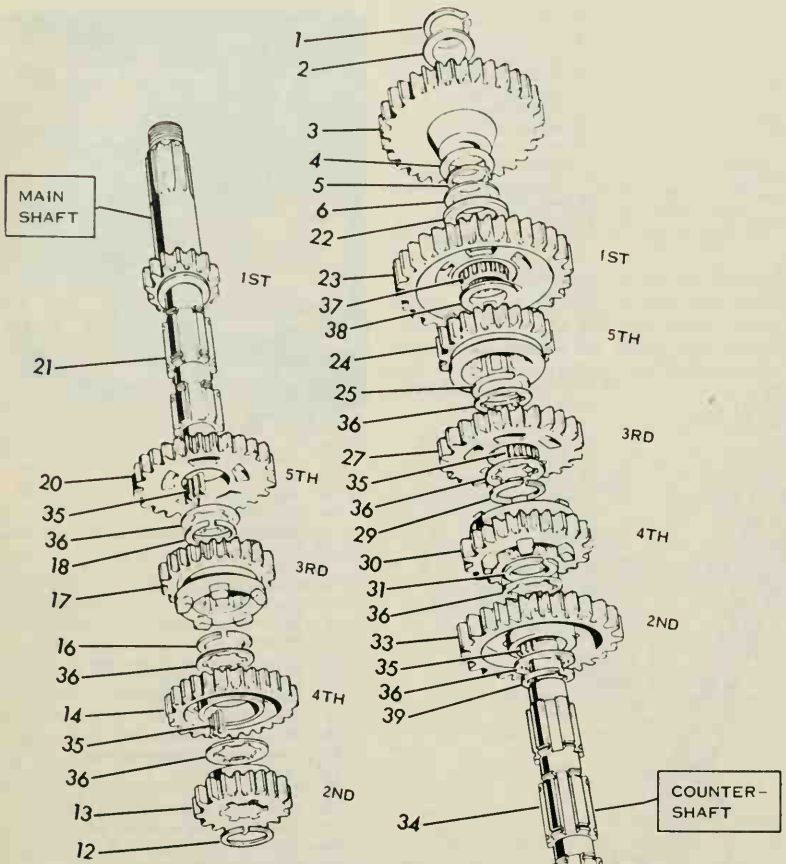
16. Gently lower the front of the engine onto something soft, support the rear of the engine, and remove the right footrest.

17. Install the engine in the reverse order of removal, taking note of the following:

a. Connect the condenser and contact point leads to the contact breaker wire stud screw.

b. Connect the red wire at the generator DF terminal and the white wire at the D+ (D plus) terminal.

c. Replace the drive chain before replacing the left side cover. Always point the rounded end of the master link in the direction of normal rotation.



d. Clean the oil filters and replenish the oil supply before attempting to turn over the engine.

a. Remove the feed line connector, washers, cylinder head nuts, and washers.

b. Remove the cylinder head assembly, push rods, rocker arm oil return pipe, and the push rod housing rubber gasket. Tap gently on the head with a soft mallet if it is reluctant to come off.

c. Cover the cylinder with a clean, oil-soaked rag.

2. Remove the head on 1967 to 1972 models in the following manner:

a. Remove the feed line connectors, washers, rocker arm oil line, rocker arm cover nuts or bolts, washers, rocker arm cover, and gasket.

b. Remove the cylinder head nuts, collars, O-rings, hose clamp (if applicable), head assembly, and head gasket. Tap gently on the head with a soft mallet if it is difficult to remove.

c. Remove the oil return pipe and O-rings, loosen the hose clamps (if applicable), and remove the hose.

d. Remove the push rod housing rubber gasket, and cover the cylinder with a clean, oil-soaked rag.

Disassembly

1. Disassemble the 1966 and earlier and 1973 and later cylinder head in the following manner:

a. Remove the rocker arm oil feed pipe connections, washers, and the rocker arm oil line taking care not to bend the oil line. This type of line will easily break from repeated bending.

b. Remove the tappet cover screws, washers, cover, gasket, and all mounting screws to the intake and exhaust rocker arm covers, gaskets, valve and shaft side rocker arm support flange covers, and gaskets.

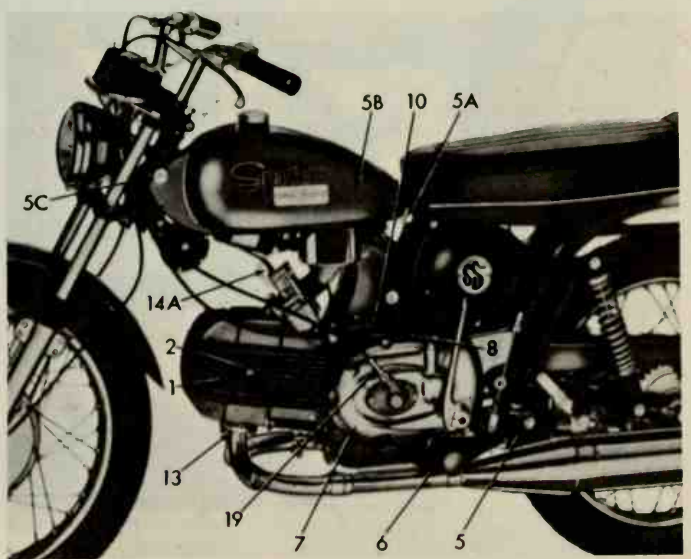
c. Remove the intake manifold assembly by removing the nuts, washers, bushing, manifold, and insulator bushing.

d. Remove the rocker arm assembly if necessary by removing the rocker arm set screw, tapping the rocker shaft free of the head, and lifting the rocker arm free. It is not necessary to disassemble the rocker arms to remove the valves.

e. Continue as described in step three.

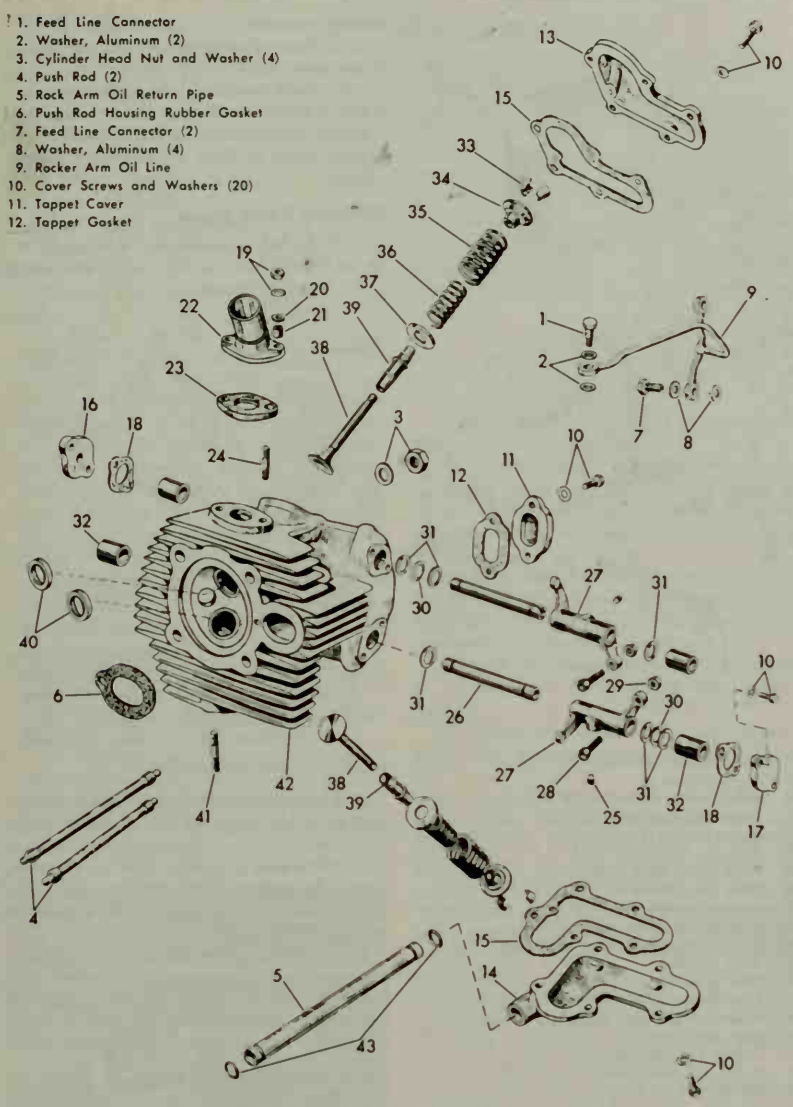
2. Disassemble the 1967 to 1972 cylinder head in the following manner:

a. Remove the rocker arm oil feed pipe connections, washers, and the rocker arm oil line, taking care not to bend the oil line. This type of line will easily break from repeated bending.



b. Remove the intake manifold assembly by removing the screws, washers, manifold, and insulating block.

c. Remove the rocker arm assemblies if repair of the valves or rocker arms is necessary, by removing the clamping bolt and lock, tapping the shaft free of the head, and lifting the rocker arm free.



d. Continue as described in step three.

3. Disassembly continued for all models.

a. Each rocker arm assembly has a spring washer among thrust washers on

one side and thrust washers only on the other. For reassembly purposes make a note of the number and placement of said devices.

b. Remove the valves by compressing them with Valve Spring Compressor (H-D part no. 97290-61P), or any suitable compressor or means of compressing the valves spring long enough to remove the valve keys.

c. Remove the valve spring upper collar, inner and outer springs, lower spring collar, and valve, and keep all the parts separate for reassembly in their original locations.

d. Remove the valve seats and guides only if replacement is necessary as described in the "Inspection and Repair" and the "Refacing and Replacing Valve Seats" sections.

Inspection

1. Clean all parts in a suitable gum and carbon-dissolving solution and blow them dry, taking care to blow all passages clear.

2. Inspect and repair the rocker arm, shaft, and bushing if worn or damaged in the following manner:

a. Remove any burrs from the rocker shaft with a hone.

b. Inspect the rocker arm pads for an unevenly worn, pitted, or damaged condition. If possible, inspect a new pad, then grind the damaged one until a similar contour is attained.

c. Replace the bushings if loose or damaged by heating the head to about 250° F with a blow torch and then driving or pressing the bushing free using a shouldered drift with a 0.469 in. pilot.

d. Drill a 0.118 in. oil hole in the intake left bushing.

e. Press the new bushing into the head after heating the head as described above. Line-ream the bushing with Reamer (H-D part no. 97414-61P) or a suitable substitute, and check to see that the oil hole is not blocked.

d. Replace the rocker arm adjusting screw ball sockets if worn or elongated.

e. Replace any springs or thrust washers in questionable condition.

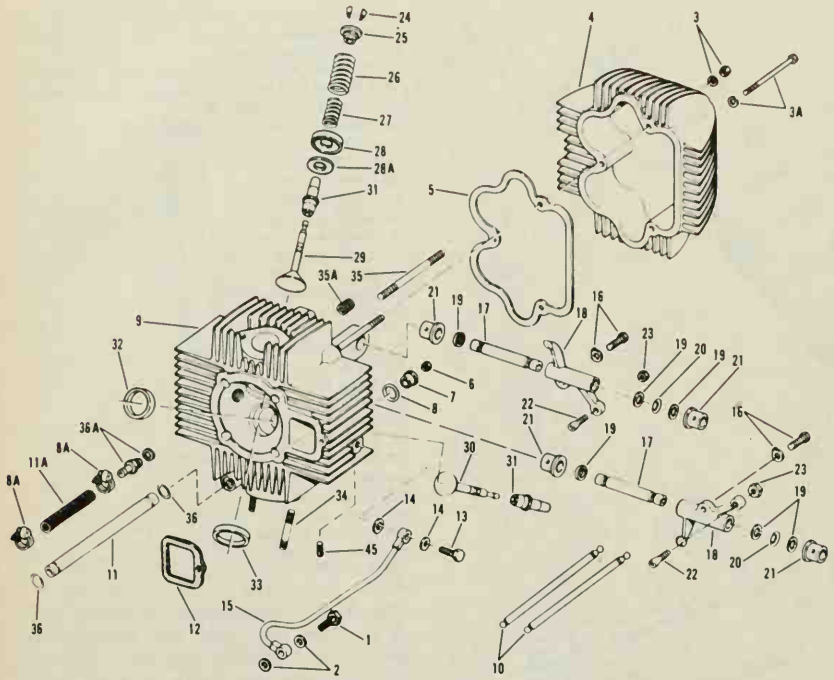
3. After the head has soaked long enough to soften any deposits, clean the outside thoroughly with a wire brush. Scrape the combustion chamber and valve port areas with a blunt blade, taking care not to gouge or scratch the head's face as this may cause combustion leakage.

4. Reclean the head as described in step one.

5. Inspect the valve spring length and tension with a Valve Spring Tester (H-D part no. 96797-47) or a suitable substitute. Springs must be replaced when 1/8 in. or more shorter than a new spring or if the tension is 5 lbs or more below the specifications listed in the "Engine and Transmission Specifications" charts.

6. Valve stem and head carbon deposits can be removed with a blunt blade or a wire wheel. Once all deposits have been removed, polish the stem with a fine grade emery cloth or steel wool. Replace any valves which are severely scored, pitted, warped or bent. Consult the "Refacing and Replacing Valve Seats" section for directions on how to clean pitted, burned, or corroded valves.

7. Inspect the valves stems and guides for an excessively loose fit, worn, or damaged condition, and replace in the following manner:



a. Consult the "Engine and Transmission Specifications Chart" for the proper fit.

b. Remove the guides by heating the head with a blow torch to about 250° F and then drifting the guide free from the chambered side with an appropriately sized, shouldered drift.

c. Choose the necessary size of oversized guide until a very tight press fit is achieved. Make sure you don't mix the guides as they are not interchangeable.

d. Replace the guide by heating the head as described above, then arbor-press the guide into place, taking care to seat the guide squarely.

e. Ream the guides using a Valve Guide Reamer (H-D part no. 97310-61) or a suitable reamer.

8. Inspect the valve face for a pitted, burned, or worn condition. The face, which should be 5/64 in. wide, may be repaired as described in the "Refacing and Replacing Valve Seats" section, but only after the valve guides are attended to.

9. Inspect the intake and exhaust pipe bolts or studs for a damaged condition and replace them if necessary.

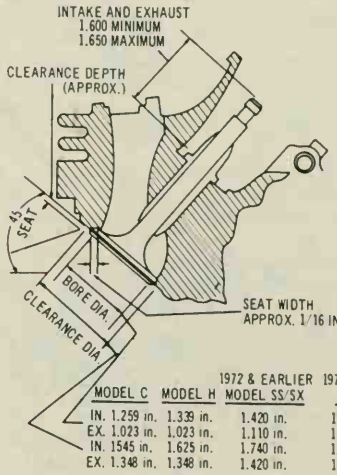
10. On 1966 and earlier models, make sure that the rocker cover oil hole is clear.

11. Inspect any gaskets you wish to reuse for a damaged or collapsed condition and replace them as necessary. It is a good practice to always replace gaskets which are under strain whenever they are removed.

Replacing Valve Seats

Valves often become pitted or worn to such an extent that they don't properly seat and compression is lost. The valve seats on an insert which is pressed into the aluminum head to provide a surface which will retain its original dimensions longer than the aluminum would. When the seat becomes wider than 1/16 in., proper seating becomes impossible and the seat relief must be counterbored or a new insert must be installed.

When the valve face becomes seriously burned or pitted, or the stem becomes heavily laden with carbon deposits, the valve must be replaced. When the valve is replaced it's good to replace the guide, especially if the stem had a lot of carbon on it.



Replace the valve seat insert in the following manner:

a. Using progressively larger reamers, bore out the old insert.

b. Heat the head with a blow torch to about 540° F and press the new insert in place. Make sure you are using the correct insert as they are not interchangeable.

Grinding Valve Seats

1. If the valve guides are to be replaced, do so before refacing the valves and seats.

	MODEL C	MODEL H	1972 & EARLIER MODEL SS/SX	1973 MODEL SS/SX

EX.	1.348 in.	1.348 in.	1.420 in.	1.495 in.

Valve seat specifications.

2. Use a valve grinding tool to grind the seat to a 45° angle so that the seat is 1/16 in. wide.

3. If the seat is greater than 1/16 in. wide, it may be narrowed by grinding the valve seat relief at a 15° angle with a suitable cutting stone.

4. Grind the valve faces to 45°, applying pressure only long enough to clean and true the surface. Avoid excessive grinding and replace the valve if the face is worn too thin.

Lapping Valves and Seats

1. After the faces and seats are ground, apply a light coat of fine lapping compound and insert the valve in the guide.

Lapping in a valve face and seat.

2. Rotate the valve several times with a grinding tool while applying light pressure at the face and seat by pulling on the valve stem. This may also be done by hand by placing a length of fuel line over the valve stem, holding the head so the stem is up, and rotating the fuel line back and forth several times.

3. To check for a well-seated valve, clean the valve and seat thoroughly and insert the valve. Apply light pressure to the seat and face by pulling on the valve, then pour some gasoline on the valve from the combustion chamber side. If it takes several seconds (10–15 is a good indication) before leakage occurs, the lapping has been successful.

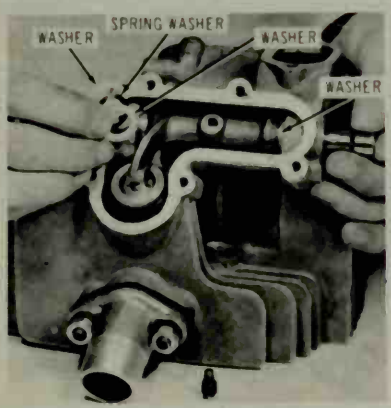
Cylinder Head Assembly

1. Assembly is basically the reverse of disassembly.

2. Install the valves in the following manner:

a. Lightly oil the intake valve stem and insert it in the guide.

b. Secure the Valve Compressor Tool (H-D part no. 97290-61P), or a suitable substitute, in a vise so the movable parts are on top, then hold the head in place so the intake valve head is in contact with the compressor's stationary jaw.



c. Assemble the lower collar, inner spring, outer spring, and upper collar in place over the valve stem.

d. Compress the springs with the compressor until there is enough room to install the keys. Place a dab of grease on the tip of a screwdriver to easily handle the keys, and always install them with the narrow part down.

e. Release the compressor and remove the head.

f. Perform the above operations on the exhaust valve. Late models have a shim which fits under the lower collar.

3. Install the rocker arm assemblies in the following manner:

Installing the rocker arm assemblies (shown is the intake valve).

a. Place the intake rocker arm in the head and slip the rocker arm shaft into the bushing on the push rod side until it can be seen between the bushing and the arm.

b. Place the appropriate number of thrust and spring washers in position.

c. Push the shaft through the washers and into the arm until the flat portion or hole is visible through the hole in the rocker arm. Position the rocker arm pad on the valve stem by increasing or decreasing the number of washers.

d. Secure the setscrew or bolt and lock.

e. Perform the above operations on the exhaust rocker arm assembly.

Cylinder Head Installation

1. Assembly is basically the reverse order of disassembly.

2. Make sure the mating faces of both the head and cylinder are perfectly clean.

3. Replace the oil return pipe oil seals on 1966 and earlier models, and insert the pipe in the left crankcase oil return hole.

4. Place the intake push rod in the push rod housing closest to the flywheel assembly. When the head is installed, the intake push rod will be above the exhaust push rod.

5. Install the exhaust push rod in the outer push rod housing. The exhaust rod is 0.040 in. longer than the intake rod on 1967 and later models.

6. Install the push rod housing rubber gasket over the push rods.

7. Slip the head in position over the mounting studs, leaving sufficient space to allow needle-nosed pliers to be inserted between the head and cylinder to grasp the push rod.

8. Rock the rocker arm down so the tappet adjusting screw can engage the appropriate push rod ball end. Repeat this procedure on the other push rod.

9. Slide the head down until it comes in contact with the cylinder mating surface.

10. Secure the head nuts until finger-tight, then diagonally torque them to 30 ft lbs.

11. Assemble the rocker arm oil line to the cylinder. Position the line on 1966 and earlier models so the crankcase connection end is between the cylinder head and rocker arm housing, and so it runs between the cooling fins along the lower right side of the cylinder and head. Place an aluminum washer on both sides of the connections, and install the connectors with the longest feed line connector in the crankcase. Wait until you are certain that all three connectors are properly aligned before securing the connectors.

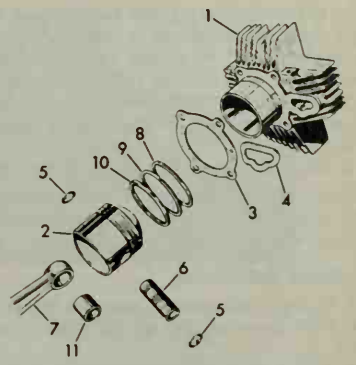
12. Adjust the tappets as described in the "Tune-Up" section.

13. Assemble the remaining components in the reverse order of disassembly. Take care not to overtighten the tappet cover screws on 1966 and earlier models as damage will result.

CYLINDER AND PISTON

Disassembly

1. Remove the cylinder head as described in the cylinder head removal section.



2. Thoroughly clean the crankcase around the base of the cylinder to prevent dirt or any other alien particles from falling into the crankcase.

3. Lift the cylinder enough to allow a clean, oil-soaked rag to be placed over the crankcase opening.

4. Remove the cylinder from the mounting studs.

5. Pry the circlips free with a sharp, pointed instrument or remove them with snap-ring pliers.

6. Heat the piston to about 250° F with a blow torch, then drift the piston pin free with a suitable drift while supporting the piston.

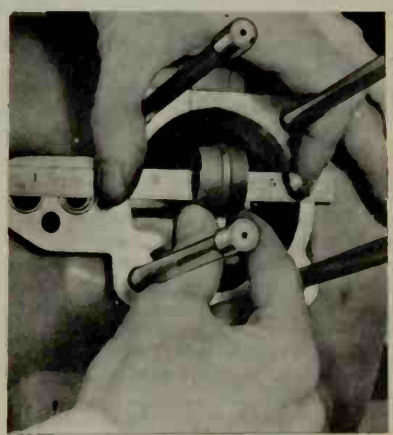
11. Piston pin bushing

Cylinder and piston assembly.

7. Using snap-ring pliers, remove the piston rings by spreading them until they'll clear the piston, and then lift them free. Once the rings have been removed, they must be replaced.



Inspection

1. Clean all parts in a suitable carbon and gum-dissolving solution until the deposits are soft, then scrub with a soft, wire brush or scrape with a blunt blade, taking care not to gouge or scratch the aluminum until all the deposits are gone. Clean the parts again and blow them dry, carefully blowing all the passages clear. Carefully clean the ring grooves with a piece of broken ring.

2. Inspect the piston pin for a pitted or grooved condition and replace it if necessary.

3. If piston pin fit in the connecting rod upper bushing has play in excess of 0.002 in., both parts must be replaced. The pin should be a light, hand press in the bushing with play not in excess of 0.001 in.

4. Inspect the piston and cylinder for cracks, burrs, gouges, grooves, or burned spots on the piston crown, and replace them if necessary.

Checking the connecting rod for lower end bearing shake.

5. If the connecting rod has vertical or side shake (as measured at the top of the connecting rod) in excess of 1/16 in., the need for a new bottom end bearing and rod assembly is indicated. Consult the "Crankcase" section for additional information.

6. Replace the circlips, piston rings, and gaskets. The gaskets may be reused if they are in perfect condition but replacement is always wise.

Cylinder Refinishing

1. Using a micrometer, measure the piston from front to rear at the base of its skirt.

2. Using an inside micrometer, measure the cylinder bore from front to rear and from side to side at a point ½ in. from the top. Repeat this procedure at various points in the middle and bottom of the ring travel area to determine whether or not the cylinder is still round.

3. Subtract the piston measurement from the cylinder measurement to arrive at the overall clearance.

4. If the cylinder is not damaged, scored, grooved, or worn 0.0025 in. or more, it need not be refinished oversize. If the clearance is not excessive, quieter operation can be achieved with standard sized pistons or the appropriate oversize pistons to fit the already oversize cylinders. If the clearance is excessive, the cylinder may be refinished to the next oversize and fitted with corresponding oversize pistons.

5. Add the desired clearance to the size of the piston to arrive at the appropriate oversize piston measurement. Pistons are available in 0.008 in. gradations from 0.008–0.032 in. oversize.

6. Hone or bore the cylinder to the piston size. Use a boring bar only if the cylinder has been scored or worn, and always leave the last 0.001 in. to be hone-finished. If the cylinder is not in bad shape, just use a hone to refinish it. If a cylinder requires reboring which will make it 0.036 in. or more oversize, it should be replaced.

Connecting Rod Bushing Replacement

1. When the connecting rod bushing and the piston pin have clearance in excess of 0.002 in., the clearance must be eliminated by one of the following methods:

   a. Ream the bushing out until the proper clearance can be attained by fitting a 0.004 or 0.008 in. oversize piston pin, and reaming the piston bosses to fit.

   b. Replace the bushing and ream it to fit a standard size piston pin unless the piston has already been fitted with an oversize pin.

2. If the engine has been taken down and the connecting rod has been removed, a suitably sized press may be used to remove and install the bushing. Always press the bushing in so the oil holes are aligned.

3. If the bushing is to be replaced during a top-end job, proceed in the following manner:

   a. Secure the connecting rod to prevent damage to it and the lower bearing.

   b. Remove the old bushing with Piston Pin Bushing Tool (H-D part no. 95970-32A) or by heating the rod with a blow torch and then carefully pressing the bushing free.

   c. Install the new bushing with the same tool or a suitable substitute, taking care to align the oil holes while pressing the bushing into place.

4. After the bushing is installed in the rod it must be reamed to provide the necessary 0.0006–0.0012 in. piston pin clearance. Use Expansion Reamer (H-D part no. 94810-65), or a suitable substitute, to perform this operation.

5. Remove the rod from whatever has been securing it and visually check the rod alignment. If the rod has been bent, it should be replaced since bending fatigues metal and one doesn't want a tired rod.

Assembly

1. Select the appropriate size piston ring by adding the desired piston-to-cylinder clearance to the piston measurement and then subtracting that figure from the measurement of the cylinder bore. The result is the size of the necessary ring. Rings are available in 0.008 in. gradations from 0.008–0.032 in. oversize. Do not use oversize pistons in a standard bore.

2. Check ring gap by holding the piston in the cylinder, in an inverted position, laying the ring on top of the piston skirt, and measuring the gap. The gap must be within 0.010–0.016 in. If the gap is too small, it may be increased by filing with a fine-cut file.

3. Install one of the piston circlips with snap-ring pliers, heat the piston with a blow torch, and lubricate the piston pin, upper rod bushing, and piston pin bosses with engine oil.

4. Cover the crankcase with a clean, oil-soaked rag. Place the piston in position on the connecting rod so the large relief valve is facing the intake side, slip the piston pin into position, and secure the remaining circlip. Remove the rag from the crankcase.

5. Dip the piston and rings in engine oil and install the piston rings by using a ring expander, or by carefully spreading the ring by hand then slipping it over the piston crown and then into place. The top ring is a plain-type compression ring, the next ring is a compression ring with a stepped inner diameter, and the bottom ring, which is installed first, is a slotted oil ring. Stagger the ring gaps but avoid having gaps on the thrust faces of the piston.

6. Check the ring side-clearance for 0.001–0.002 in. end-play. If the ring is too loose, the ring groove is probably worn and the piston must be replaced. If the ring has been installed and then removed, it still may be used since rings break rather than bend.

7. Place the cylinder base gaskets in position over the mounting studs.

8. Rough up the cylinder bore with no. 150 carborundum emery paper or a no. 300 hone if the cylinder wasn't refinished. This will provide a surface conducive to efficient ring seating and lubrication.

9. If a ring compressor is to be used assemble it now. Lubricate the cylinder walls with engine oil, and rotate the engine until the piston is at its lowest point of travel.

10. Carefully start the cylinder on the mounting studs until about 1½–2 in. of the studs is covered. Gently rotate the engine until the piston is aligned with the cylinder bore. Compress the first ring by hand and insert the piston into the bore by rotating the engine slightly. It is best to rotate the engine by placing the machine in high gear and then turning the rear wheel by hand. Continue to insert the piston until it is entirely in the cylinder.

11. Lower the cylinder onto its crankcase mating surface while holding the push rod housing rubber gasket in place.

12. Complete assembly in the reverse order of disassembly as directed in the section on the cylinder head.

Crankcase

DISASSEMBLY

1. Remove the engine from the frame as described in the engine "Removal and Installation" section.

2. Remove the generator as described in the "Generator" section on pre-1972 models. On 1973 and later models remove the alternator as described in the "Alternator" section.

3. Remove the starter clutch as described in the "Starter" section.

4. Remove the drive sprocket as described in the "Transmission" section.

5. Remove the cylinder head as described in the "Cylinder Head" section.

6. Remove the cylinder and piston assembly as described in the "Cylinder and Piston" section.

7. Remove the gearcase cover, camshaft, tappet assemblies, oil pump, pinion shaft gears, and the pinion shaft bearing lockring and spacers as described in the "Transmission" and "Lubrication" sections.

8. Remove the clutch assembly as described in the "Clutch" section for 1968 and earlier models. On 1973 and later models remove the electric starter.

9. On pre 1972 models; check the crankshaft end-play with a dial indicator in the following manner:

   a. Mount Crankshaft Tool (H-D part no. 97295-61P) on the right crankcase and the dial indicator on the left crankcase.

   b. Push the crankshaft as far to the left as it will go.

   c. Remove the tool and mount Crankshaft Tool (H-D part no. 97297-61P) in its place.

   d. Pull the shaft all the way back to the right.

   e. End-play is regulated by the number of spacer washers used. Washers are available in 0.05 and 0.10 mm sizes or may be replaced with two spring washers (which is the recommended technique).

   f. If the tools are not available the crankshaft may be manipulated with hand tools.

10. Drift the dowel pins free with a suitably sized drift and remove the three allen screws and seven bolts and washers which secure the crankcase halves. If the dowel pins are difficult to remove, heat the case

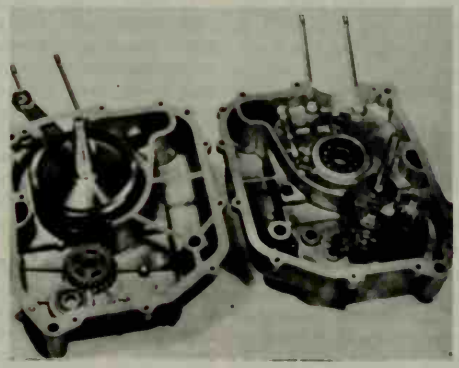
around each pin with a blow torch.

11. Separate the crankcase halves with Crankshaft Tool (H-D part no. 97295-61P) or a suitable substitute. The tool mounts on the right case over the flywheel pinion shaft and presses the cases apart by exerting pressure on the flywheel assembly. Tap on the mainshaft with a soft mallet while using the tool and make sure the cases remain parallel during the entire operation.



12. Remove the transmission as described in the "Transmission" section.

Removing recessed allen screw from the left crankcase half.

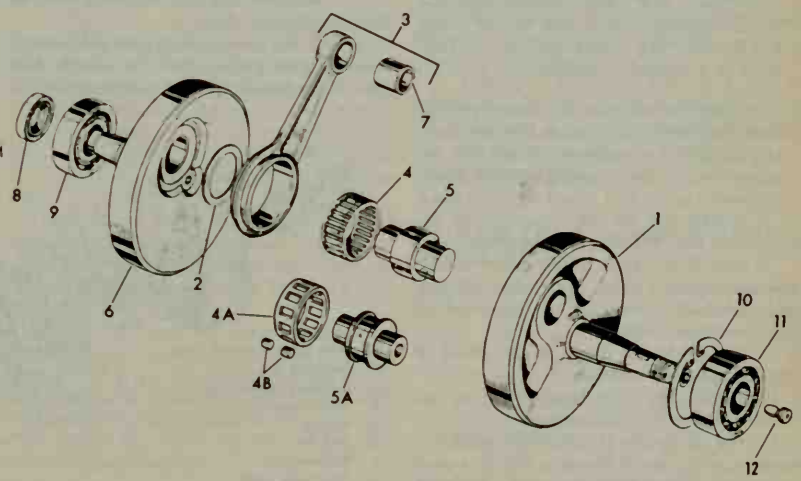
The separated crankcases.

13. Remove the pinion bearing lockring with snap-ring pliers, then press the pinion shaft bearing from the crankcase. Bearing damage can be avoided by covering the bearing with a flat plate before pressing. Remove the crankshaft orifice plug (if applicable).

14. Press the flywheel assembly from the left case using Crankshaft Tool (H-D part no. 97295-61P) or a suitable substitute.

15. The countershaft ball bearing may now be removed with a puller if so desired.



16. Remove the generator shaft bearing oil seal and press the bearing free.

INSPECTION

1. Clean all parts in a suitable solvent and blow them dry, taking care to clear the oil passages in the right flywheel and crankpin.

2. Check the main bearings for a pitted, worn, or damaged condition, excessive play, or rough action, and replace them as necessary by removing the seals and lockrings and pressing the bearings in and out. Heating the case around the bearing boss will aid in installation.

3. Inspect the pinion shaft cover bushing for a worn or damaged condition or

excessive play and replace it as necessary.

4. Inspect the camshaft support plate for a worn or damaged condition and replace it as necessary.

5. Inspect the connecting rod, connecting rod bearing set, crankpin, and flywheel thrust washers for a worn, damaged, or loose condition, and replace them as an entire assembly.

ASSEMBLY

1. Press all bearings, bushings, and oil seals which have been removed back into the crankcase. Heating the case with a blow torch will aid in installing the bearings and bushings.

2. Install the pinion shaft bearing lockring.

3. Secure the left flywheel shaft in a copper or wood-jawed vise. Lightly oil the pinion shaft and position the right case on it.

4. Assemble the Crankshaft Tool (H-D part no. 97297-61P), or a suitable substitute, to the pinion shaft and draw the flywheel assembly through the right case, taking care not to damage the generator frame stud. Secure the pinion shaft bearing lockring in its groove.

5. Install the transmission as described in the "Transmission" section.

6. Assemble the cases in the following manner:

a. Place Oil Sleeve Installing Tool (H-D part no. 95629-63), or a suitable substitute, on the flywheel shaft to avoid damaging the oil seal lip while assembling the case.

b. Secure the crankcase and engine mounting stud boss gaskets to the right case with a suitable sealer, using new gaskets only.

c. Slide the cases together and rotate the main drive gear to test for positive meshing of the transmission gears.

d. Draw the cases evenly together while tapping with a soft mallet using Crankcase Tool (H-D part no. 97295-61P) or a suitable substitute.

e. Tap the cases so the dowel pins fit into their receptacles once the case mating surfaces have seated against one another. Secure the remaining seven bolts, washers, nuts, and three allen screws.

7. Install the oil filter screens as described in the "Maintenance" section.

8. Install the gear shifter pawl carrier assembly, pinion shaft gears, and tappets and camshaft assemblies as described in the "Gearcase" section.

9. Install the oil pump as described in the "Lubrication" section.

10. Install the clutch assembly as described in the "Clutch" section.

11. On all Sprint H and 1963 Model C models, use a wood block to tap in a new crankshaft orifice plug, then use a piece of wire or a no. 53 (0.0595 in.) drill to make sure the oil hole is clear and of the proper size (if applicable).

12. Install the gearcase cover as described in the "Gearcase" section.

13. Install the piston, cylinder, and cylinder head as previously described in the "Top End" section.

14. Install the drive sprocket and cover as described in the "Transmission" section.

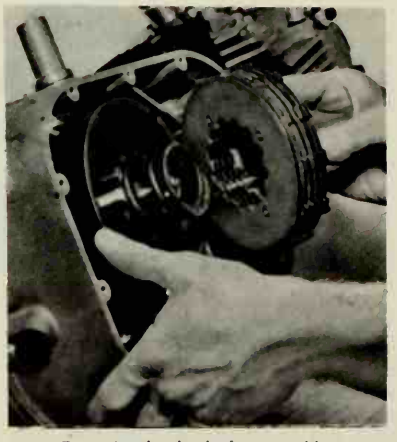
15. Install the starter clutch assembly as described in the "Starter" section.

16. Install the generator as described in the "Electrical" section.

17. Install the engine in the chassis as described in the engine "Removal and Installation" section.

Clutch

DISASSEMBLY (1968 AND EARLIER MODELS)



1. Place a drip pan beneath the right side clutch cover, use a wrench to rotate the release lever forward, disengage the cable from the lever, and remove the foot shift lever, cover screws, cover, and cover gasket. Cover all gear case openings with a clean, oil-soaked towel.

2. Compress the clutch spring with Clutch Spring Compressor (H-D part no. 97293-61P) or a suitable substitute. The compressor's end bolts screw into the gearcase cover holes. When the spring is compressed enough, pry the drive outer plate lockring free and remove the compressor.

3. Remove the releasing disc cap, bearing, and the entire clutch plate and disc assembly. A piece of wire can be used to lift each disc and plate to slide them out, if so desired, once the backing plate nuts and washers have been removed. The machine can also be tilted over far enough to let the plates and discs slide out.

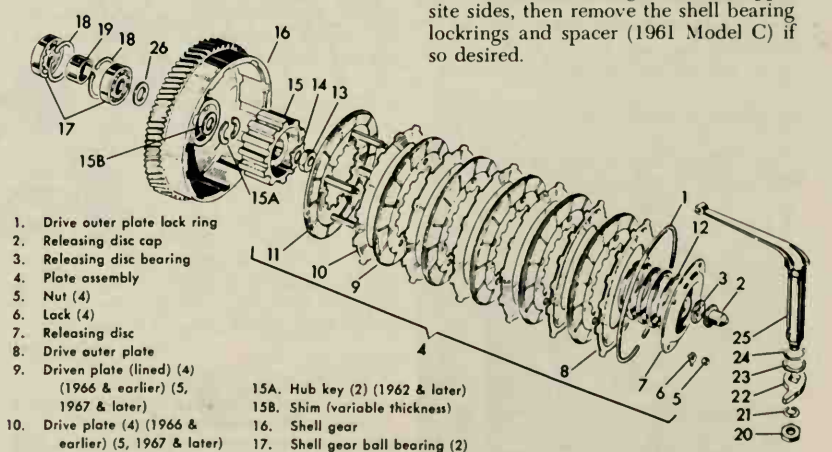
4. Remove the clutch spring from the clutch hub and assemble the Clutch Holding Tool (H-D part no. 97291-61PA) or substitute some means of securing the clutch, such as blocking the clutch gear with a wooden door stop. Remove the clutch hub nut and lock, then pull the hub from its splined shaft with Crankshaft Pinion Gear and Clutch Hub Puller (H-D part no. 97294-61B) or a suitable gear puller. The mounting studs fit in the tapped holes in the hub. Remove the hub keys and spacer shim.

5. Pull the clutch shell gear free with a suitable gear puller. Pull the clutch shell gear inner bearing free if it remains on the shaft with Puller (H-D part no. 95960-48) and Two-Claw Puller (H-D part no. 97292-61P) or a suitable substitute which will grab the notches in the puller body. Remove the spacing shim if applicable.

Removing the clutch plate assembly.

INSPECTION

1. Clean all parts other than the friction discs in a suitable solvent and blow them dry.



2. Inspect the clutch spring for a collapsed or damaged condition. If the spring measures $^{3}/_{32}$ in. less than the standard $1^{29}/_{32}$ in. or if it is damaged, it must be replaced.

3. Inspect the clutch plates and discs for a warped, scored, or heat-damaged condition, and replace if necessary. When replacing clutch plates and discs, it is a good practice to replace them as a set. Burrs may be filed off the teeth of the discs.

4. Examine the clutch hub, clutch shell gear, and the primary drive gear for worn or damaged teeth and replace them if necessary. The shell and primary gears must be replaced as a set.

5. Inspect the clutch shell bearings for excessive side or vetical play, wear, or rough motion, and replace if necessary in the following manner:

a. Press the bearings out from opposite sides, then remove the shell bearing lockrings and spacer (1961 Model C) if so desired.

b. When installing the new bearings, first install the lockrings and spacer, then press the bearings in until seated against the lockrings.

6. Inspect the clutch releasing disc, disc bearing, and disc cap for a worn or damaged condition or rough bearing motion and replace them if necessary. The bearing action must be free and the disc cap must be free on the transmission mainshaft.

RELEASE LEVER REMOVAL AND INSTALLATION

1. Remove the contact breaker wires from the clutch cover.

2. Remove the release lever nut, lockwasher, operating cam, lockring, and release lever.

3. Inspect the oil seal for a worn or damaged condition and replace it and any other worn or damaged components as necessary.

4. Assemble the lever assembly in the following manner:

a. Slip the oil seal in place on the release lever and install the lever in the cover.

b. Secure the lever with the lockring which seats in a groove in the lever.

c. Position the operating cam on the release lever so the lever points to the center and the cam is to the rear of the engine when the cover is installed.

d. Secure the assembly to the cover with the release lever lockwasher and nut.

ASSEMBLY

1. Assembly is in the reverse order of disassembly.

2. Proceed as follows for units equipped with a drive take-up gear:

a. Slip the clutch shell gear onto the transmission mainshaft far enough to engage the shell and take-up gear teeth.

Preloading the clutch take-up gear.

b. Rotate the clutch shell gear clockwise to rotate the take-up gear counterclockwise. When the take-up gear has advanced three teeth on the clutch drive gear, press the shell the remaining distance to engage the drive gear completely.

3. On units with a single-piece drive gear, merely press the shell onto the mainshaft until it engages the teeth of the drive gear.

4. Install the spacer shim and hub keys if applicable. Select the appropriate shim which will reduce shell end-play to a minimum when the keys are installed.

5. Assemble the clutch hub so the small hole faces out. Hold the hub in the same manner as in step four of the "Disassembly" section while installing the hub nut.

6. Install the clutch plates and discs with a steel plate on the inside against the backing plate then a friction disc and so on until six steel plates and five friction discs have been installed.

7. Slip the releasing disc on the backing plate studs so the spring seat is facing in toward the clutch plates, then secure the stud locks and nuts.

8. Slip the clutch spring into the clutch hub and then position the clutch plate and disc assembly onto the hub, pressing in until seated.

9. Place the drive outer plate over the clutch plate assembly so the shouldered side faces out.

10. Assemble the releasing disc bearing and cap on the releasing disc and assemble the Clutch Spring Compressor (H-D part no. 97293-61P), or a suitable substitute, to compress the spring.

11. When the plates and discs are properly aligned with the hub and shell, secure the entire assembly with the drive outer plate lockring which seats in a groove in the shell. Remove the compressing device and install the clutch cover and shift lever.

CLUTCH CABLE REPLACEMENT

1. Rotate the release lever forward with a wrench and disengage the clutch cable.

2. Loosen the cable block screws and remove the cable block from the cable

3. Disengage the cable and housing from the cable adjusting screw.

4. Align the slots in the handlever adjusting screw and nut, and free the cable at the handlever.

5. The cable may now be slipped out through the top of the coil or the cable and coil may be removed from the frame.

6. Grease the cable or lubricate it with a chain lubricating compound or engine oil while slipping it back into the coil. The coil is run through the right fork brackets and down through the guide near the horn.

7. Secure the cable at the handlever and adjust the adjusting screw and nut in as far as they will go. (On 1961–62 C models, the cable end button short end goes into the lever first.)

8. Slip the adjusting screw assembly on the cable end and run the cable through, and secure it to the cable securing block, and position it so the shoulder of the cable block seats on the release lever.

9. Adjust the clutch as described in the "Maintenance" section.

DISASSEMBLY (1969 AND LATER MODELS)

1. Remove the footshift lever, clutch cover screws (from the smaller cover located on the front of the right crankcase cover), and the clutch cover.

2. Diagonally loosen the clutch spring nuts, so there is even pressure exerted against the pressure plate at all times, with Clutch Releasing Disc Nut Wrench (H-D part no. 94670-66P) or a screwdriver. Using a screwdriver may damage the nuts; they should be replaced if removed in this manner.

3. Remove the springs, cups, pressure plate, clutch plates and discs, and the steel-lined backing plate.

4. Secure the clutch hub with Clutch Lock Tool (H-D part no. 97177-69P) or by jamming a wooden door stop between the shell gear and the crankcase. Remove the hub nut and lock, then pull the hub free with a gear puller.

5. Remove the clutch hub O-ring, bend back the ears of the clutch shell nut lock, and remove the shell nut with Clutch Shell Nut Wrench (H-D part no. 97235-66P) or a suitable substitute. Remove the nut lock.

6. Remove the clutch shell, washer, clutch drive gear, clutch gear needle bearings, and the gear spacer washers.

INSPECTION

1. Clean all parts other than the friction discs in a suitable solvent and blow them dry.

2. Check the clutch springs for a collapsed or damaged condition and replace them if necessary. The free-length of a new clutch spring is $1^{19}/_{32}$ in.; any spring which is shorter by $^{3}/_{32}$ in., or more, should be replaced. Springs should be replaced as a complete set.

3. Inspect the clutch plates and discs for a warped, scored, burned, or damaged condition, and replace as necessary. When replacing clutch plates and discs, it is a good practice to replace them as a set. Burrs may be removed from the disc teeth with a file.

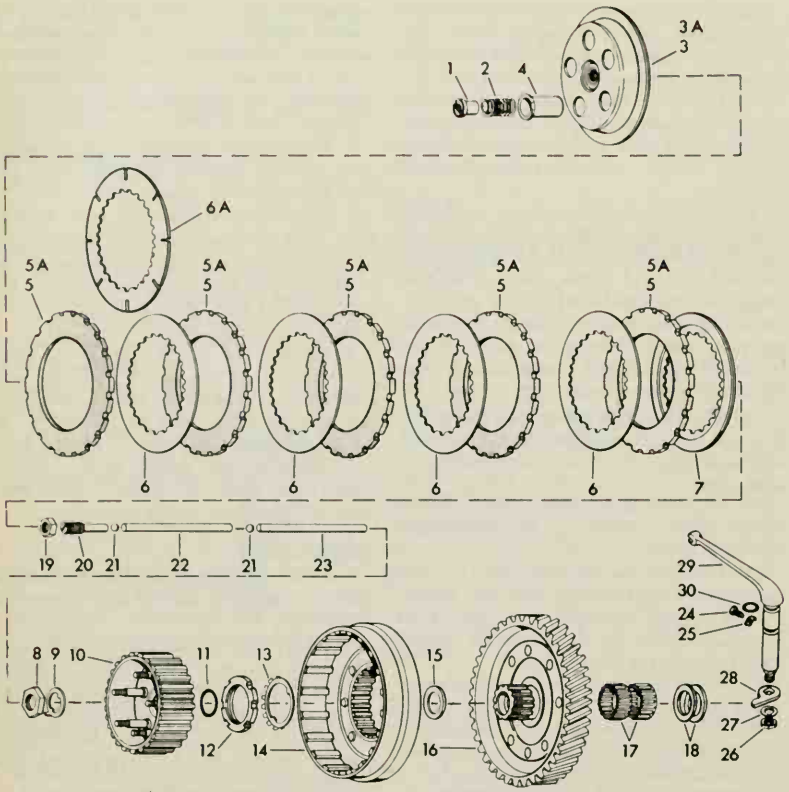
4. Examine the O-ring for a cracked, rough, warped, or damaged condition and replace it if necessary. If a new O-ring is available, it should be used.

5. Examine the lip seal of the crankcase for a worn or damaged condition and replace it if necessary.

6. Inspect the clutch hub studs for a loose, stripped, or damaged condition and replace them if necessary by drilling out the old stud with a $^{5}/_{16}$ in. drill and riveting in a new stud.

RELEASE LEVER REMOVAL AND INSTALLATION

1. Remove the left crankcase cover screws then tap on the cover with a soft mallet while pulling on the kick-starter lever.



2. Remove the release lever nut, lockwasher, operating cam, retaining screw, lock, and release lever.

3. Inspect the oil seal and all other parts for a worn or damaged condition and replace them as necessary.

4. Assemble the release lever assembly in the following manner:

a. Slip the oil seal on the release lever and install the lever in the crankcase cover.

b. Position the operating cam on the release lever so the lever points to the center and the cam is to the rear of the engine when the cover is installed.

c. Secure the assembly with the clutch lever lockwasher and nut, then install the retaining screw and lock.

CLUTCH RELEASE PUSH ROD REMOVAL AND INSTALLATION

1. Remove both crankcase covers.
2. Loosen the push rod adjusting nut and remove the adjusting screw from the clutch pressure disc.
3. Push the two rods and balls out with a piece of wire or a spare rod.
4. When installing the rods again, be sure that the rounded end of the left-side push rod seats against the clutch lever operating cam.

CLUTCH CABLE REPLACEMENT

1. Consult the "Clutch Cable Replacement" section for the 1968 and earlier models.

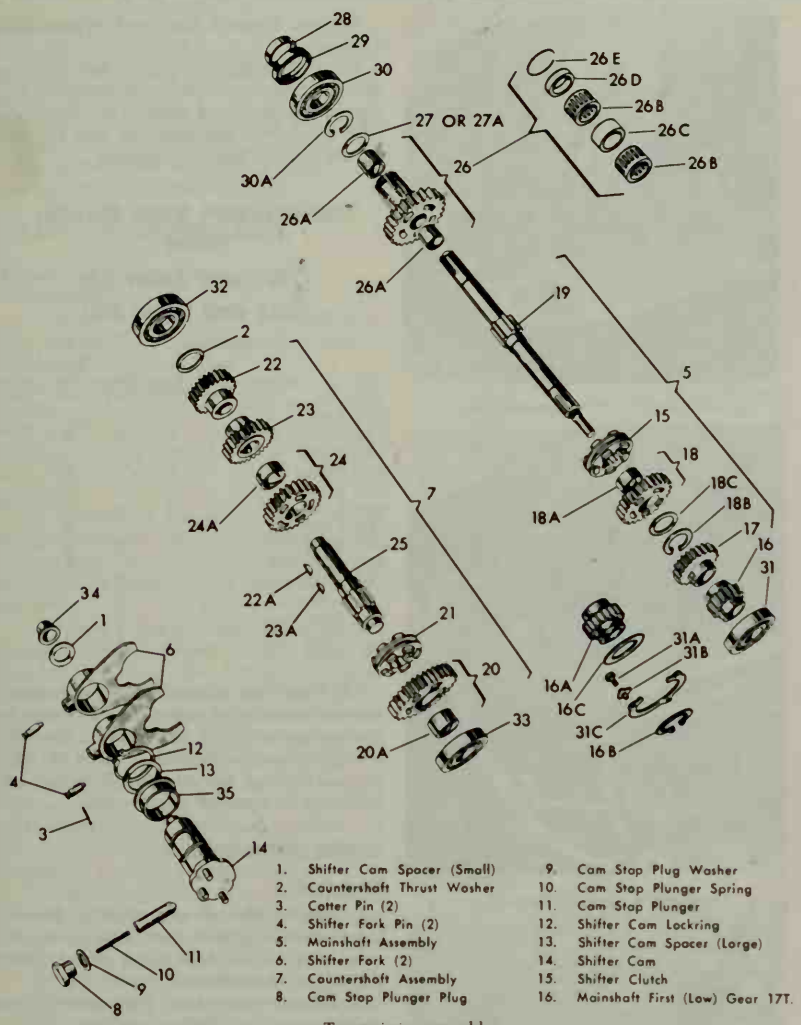
Transmission

If it becomes necessary to take down your transmission, you may as well go over the entire machine and overhaul the top and bottom ends since they will have to be dismantled in the process.

REMOVAL AND REPLACEMENT

1. Remove the engine from the frame as described in the engine "Removal and Installation" section.
2. Separate the crankcase halves as described in the "Crankcase" section.
3. Replacement is in the reverse order of removal.

DISASSEMBLY



1. Place the right crankcase on a work bench so the gear assemblies are pointing up.
2. Remove the small shifter cam spacer, the countershaft thrust washer, the shifter fork cotter pins, the shifter fork pins, and the mainshaft first gear lockring (if applicable).
3. Mount Clutch Spring Compressor (H-D part no. 97293-61P) or a suitable substitute to the outer portion of the crankcase and press the mainshaft assembly free of the right-side mainshaft bearing, then remove the shifter fork connected to the mainshaft from the shifter cam.
4. Drift the countershaft assembly free of the right-side countershaft bearing, and remove the shifter fork, which is connected to the countershaft, from the shifter cam.
5. Remove the cam stop plunger plug, plug washer, plunger spring, plunger, shifter cam lockring, large shifter cam spacer, and the shifter cam.
6. Further work on the transmission should be carried out by your local dealer or by a qualified machinist.

INSPECTION

1. Clean all parts in a suitable solvent and blow them dry.
2. Inspect all the gears for wear, damage, chipped dogs, battered dog slots, pits, and grooves, and replace them as necessary. Those gears which mesh together should be replaced in sets.
3. Inspect the mainshaft and countershaft for a warped, worn, pitted, grooved, or excessively worn condition, especially at the bearing surfaces, and replace them as necessary.
4. Inspect all bushings for wear, damage, or an excessively loose fit and replace them as necessary by drifting them in and out with a suitably sized drift. Ream the mainshaft third gear, countershaft first gear, and the countershaft second gear bushings with Reamer (H-D part no. 94806-64) or a suitable substitute, and the sprocket gear bushings with Reamer (H-D part no. 94806-63) or a suitable substitute.
5. Inspect the sprocket gear needle bearings and shaft (1969 and later models) for a worn, pitted, warped, or damaged condition, or for rough bearing motion, and replace them as necessary.
6. Inspect the shifter clutches for worn or damaged dogs and shifter fork grooves, and replace them as necessary.
7. Inspect the shifter cam for grooved or worn cam slots in the running gear positions and replace it if necessary.
8. Inspect the shifter forks for a worn, warped, or grooved condition at the fork fingers. Do not try to save the forks by bending them straight since this will merely tax the metal and cause them to fail before too long.
9. Inspect the shifter fork pins, the shifter cam stop plunger, and the plunger spring for a worn or damaged condition, especially on the plunger thrust face, and for free plunger and spring movement, and replace them as necessary. The spring free-length should be 1.535 in., and must be replaced if collapsed to a shorter length.
10. Inspect the bushings and bearings for wear, pitting, damage, excessive play, or rough motion and replace them as necessary in the following manner:

a. Using a suitable drift, press out the right-side mainshaft, countershaft, and shifter cam bearings from the right crankcase half. The right-side mainshaft retainer bolt, lock, and retainer (if applicable) will have to be removed before the bearing can be removed.

b. Use a suitable puller device to remove the blind left-side countershaft bearing.

d. Pry out the left-side sprocket gear oil seal then press the left-side mainshaft bearing from the outside-in using a suitable drift.

e. Line-ream the right-side shifter cam bushing with Right Bushing Reamer (H-D part no. 97322-61P), or a suitable substitute, and the left-side shifter cam bushing with Left Bushing Reamer (H-D part no. 97318-61P) or a suitable substitute. Always rotate the reamer clockwise, even when withdrawing it.

ASSEMBLY

1. Press the replacement oil seals into place if they have been removed.

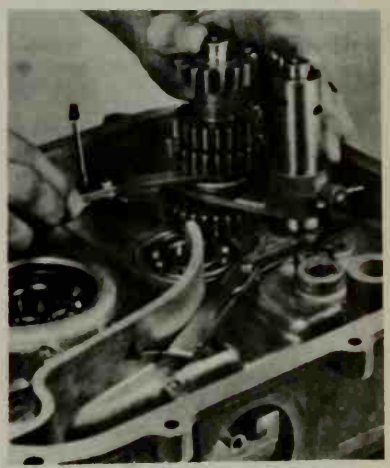
2. Install the right mainshaft bearing retainer bolt, lock, and retainer (if applicable).

3. Slip the shifter cam into place in the right crankcase, then install the shifter cam lockring, cam stop plunger, plunger spring, plug washer, and the plunger plug which must be snugly tightened down.

4. Install the countershaft assembly in the following manner:

a. Position the shifter fork so the fork fingers engage the shifter clutch shoulder closest to the second gear.

The countershaft and mainshaft assemblies.



b. Slip the shifter fork onto the shifter cam while installing the countershaft with the first gear seating in the right-side countershaft bearing, tapping the shaft with a soft mallet if necessary.

5. Determine the size of the appropriate large shifter cam spacer in the following manner:

a. Install the shifter fork pin and cotter pin into the shifter fork mounted on the shifter cam.

b. Place the transmission in the Neutral position.

c. Use a feeler gauge inserted between the shifter cam bushing and the shifter cam lockring (the gauge designated by "A" in the accompanying illustration) to raise the cam by increasing the number of the feeler gauge blades. Use a second feeler gauge (designated by "B") to measure the distance between the first gear and the shifter clutch, and the shifter clutch and the second gear. Increase the size of "A" until the two distances measured by "B" are exactly equal.

Determining the correct shifter cam spacer thickness.

d. Subtract 0.003 in. (the correct amount of end-play for the shifter cam) from the measurement of "A" to arrive at the appropriate size large shifter cam spacer. Spacers are available in 0.012, 0.020, 0.028, 0.036, 0.040, and 0.044 in. sizes. Use the spacer which comes closest to the measurement arrived at.

e. Remove and disassemble the shifter cam assembly, insert the large shifter cam spacer, and reassemble and install the shifter cam.

6. Rotate the shifter cam until the shifter fork pin holes align with the appropriate grooves in the cam. Secure the fork pins and install new cotter pins.

7. Temporarily assemble the original small shifter cam spacer and countershaft thrust washer on their respective shafts.

8. Insert the two sprocket gear bushings into the sprocket gear (if applicable) or install the bearings and bushings used in 1969 and later models. On the 1968 and earlier models where bushings are exclusively used, the bushings must be reamed with Sprocket Gear Bushing Reamer (H-D part no. 94806-63) or a suitable substitute if a new sprocket gear, gear bushings, or mainshaft is to be installed.

9. Insert the mainshaft sprocket spacer into the sprocket gear oil seal.

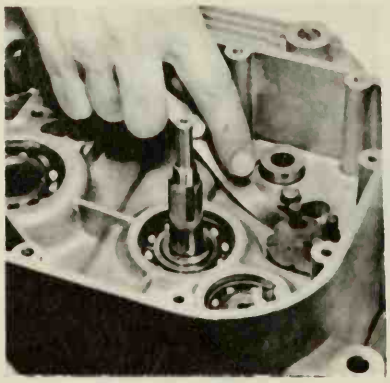
10. Place the sprocket gear spacer on the splined end of the gear, secure it with the left bearing retainer (if applicable), and install the assembly in the left mainshaft bearing.

11. Select appropriately sized spacers to take up the shaft's end-play in the following manner:

a. Remove the flywheel from the left crankcase half as described in the "Crankcase" section, and check all bearings to make sure they are completely seated.

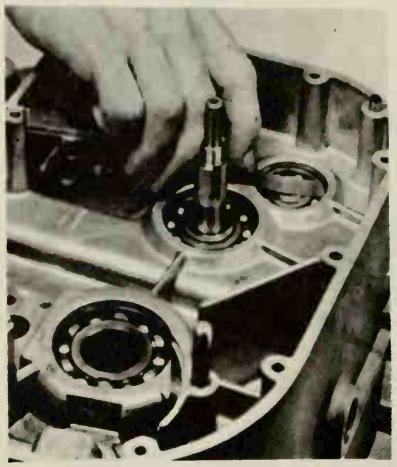
b. Install the crankcase gasket and assemble the crankcase halves with at least two bolts.

c. Mount a dial indicator to one of the crankcase halves so the plunger rests on the end of one of the shafts.



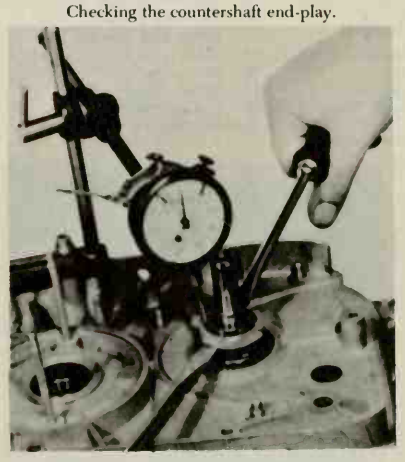
d. Shift the shafts to the end of their travel opposite the dial indicator and remember to tap the sprocket gear down, in addition to the mainshaft.

e. Shift the shafts all the way toward the dial indicator so the indicator's plunger is depressed by the shaft. Place no pressure on the shaft when reading the indicator, and repeat the operation for each of the shafts several times to be sure you have arrived at an accurate reading.



f. The end-play specifications are as follows:

1. The shifter cam end-play is measured on the right side and must be within 0.004–0.008 in. The shim is assembled on the left end of the shaft. The cam can be moved with the aid of a pair of pliers, or measured with a feeler gauge.



2. The countershaft end-play is measured on the right side and must be within 0.004–0.008 in. The shim is assembled on the left end of the shaft. The countershaft may be shifted with the aid of a long screwdriver inserted through the cylinder base opening and under the countershaft fourth gear, or measured with a feeler gauge.

Checking the shifter cam end-play.

Checking the countershaft end-play.

Checking the mainshaft end-play.

3. The mainshaft end-play is measured on the left side of the crankcase and must be within 0.008–0.010 in. The shim is assembled on the right side of the shaft. The mainshaft can be shifted with the aid of two screwdrivers as indicated in the illustration, and measured with a dial indicator or a feeler gauge.

g. If the end-play exceeds the set limits, it can be corrected by inserting the appropriate size of shim washer which will reduce the play the necessary amount. Consult the chart of available shims.

13. Disassemble the crankcases and insert the correct size shims. Reassemble the cases once more and recheck the end-play. The crankshaft end-play can also be corrected at this time if so desired.

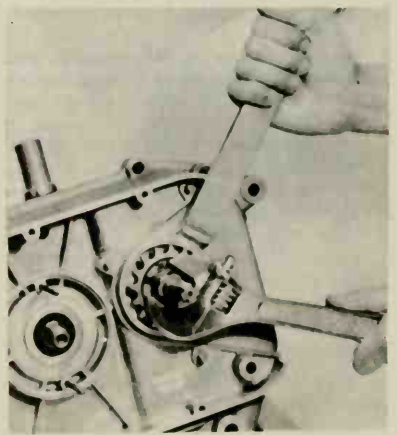
14. Install the crankshaft, then reassemble and install the engine in the frame in the reverse order of disassembly. Remember to replenish the transmission oil supply as well as the engine oil before attempting to turn the engine over.



DRIVE SPROCKET

Removal

1. Remove the left side cover by removing the cover screws then tapping on the sides of the cover with a soft mallet while pulling on the kick-start lever.

2. Remove the starter gear assembly as described in the "Starter" section.

3. Remove the sprocket cover nuts, washers, and cover.

Removing the drive sprocket.

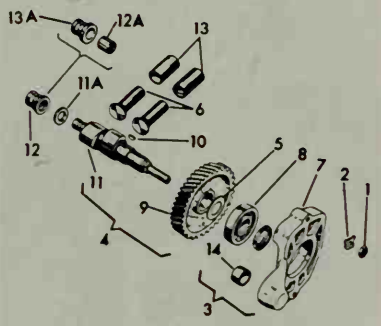
4. Hold the sprocket with the Sprocket Holding Tool (H-D part no. varies with the number of sprocket teeth), or some other means of immobilizing the sprocket, then remove the sprocket nut with a suitable wrench.

5. Remove the lock and pull the sprocket from the sprocket gear. It may be necessary to use a gear puller.

Assembly

1. Slip the sprocket on the sprocket gear with the shouldered side facing the crankcase.
2. Install the lockwasher and nut in the reverse method of removal.
3. Complete the assembly process in the reverse order of disassembly.

GEARCASE TIMING GEARS



Gearcase Cover Removal and Installation

1. If the engine is to be removed from the chassis, do so as directed in engine "Removal and Installation."
2. If the engine is to remain in the chassis, the motorcycle must be tipped over on the left side, at an angle which is sufficient to keep the oil from draining out, or a drip pan should be placed under the gearcase.
3. Disconnect the clutch cable at the release lever on 1968 and earlier models by rotating the lever forward with a wrench and then freeing the cable from the lever.
4. Remove the footshift lever, contact breaker cover screws, cover, contact breaker cam screw, the clutch assembly on 1969 and later models (as described in the "Clutch" section), the eleven cover screws, the crankcase dipstick, the cover gasket, and the cover. On 1968 and earlier models, the release lever must be rotated forward to remove the cover. As soon as the cover is removed, place a clean, oil-soaked rag over all open holes to prevent foreign objects from entering the crankcase.
5. Before installing the cover, make sure the O-rings from the shifter pawl carrier shaft and the cover pad hole recess are correctly positioned.
6. Make sure the automatic spark advance is correctly located on the camshaft as described in the "Contact Breaker" section.
7. Mount and temporarily secure the cover gasket and cover by inserting, but not tightening, the cover screws.
8. Insert the crankcase dipstick in the cover but do not secure it.
9. Evenly tighten down all of the cover screws until the cover is uniformly secure. Tighten down the dipstick after checking the oil level.
10. Secure the shifter cam assembly.
11. Mount the engine in the frame if it has been removed as described in the engine "Removal and Installation" section.
12. Install the contact breaker cover with the smaller hole on the bottom, and secure the cover screws.
13. Engage the clutch cable in the release lever. Rotate the lever forward using a suitable wrench on 1968 and earlier models.
14. Adjust the clutch as described in the "Maintenance" section.
15. Install the shift lever so the arm is just below the contact breaker cover.

CAMSHAFT AND TAPPETS

Removal

1. Remove the camshaft support assembly nuts, locks, and assembly on 1968 and earlier models.

1. Nut (2) (1968 & earlier)
2. Lock (2) (1968 & earlier)
3. Support assembly (1968 & earlier)
4. Camshaft assembly
5. Thrust washer

12. Camshaft crankcase bushing (1963 & earlier)
12A. Camshaft crankcase needle bearing (1964 & later)
13. Tappet bushing (2)
13A. Needle bearing bushing (1964 & later)
14. Pinion shaft bushing

Camshaft assembly.

2. Remove the camshaft assembly from the camshaft bushing or bearing, then remove the thrust washer and free the tappets from the tappet bushings. The tappets must be kept separate for reassembly in their original positions. The inner tappet is the intake tappet; the outer one is the exhaust.

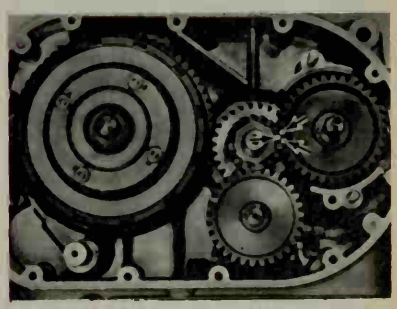
Inspection

1. Clean all parts in a suitable solvent and blow them dry.
2. Inspect the camshaft for a worn, pitted, rough, or damaged condition and replace if necessary.
3. Inspect the cam gear for a worn or damaged condition, and, if replacement is necessary, press it from the camshaft, i stall a new key in the shaft, and press a new gear into place with the recessed side facing out. Blow the shaft oil passages clear to make sure they haven't been clogged.
4. Inspect the camshaft bushings and bearing for excessive wear, play, pitting, damage, or rough motion, and replace as necessary in the following manner:

a. The camshaft bushings come in two varieties. Any 1963 or earlier models have a plain bronze bushing which is pressed directly into the crankcase; 1964 and later models have a steel bushing mounted in the case into which a needle bearing is pressed. To replace either type, the crankcases must be separated as described in the "Crankcase" section. The bearing or bushing is pressed out with a suitable, shouldered drift from the inside, and pressed in from the outside in a similar manner.

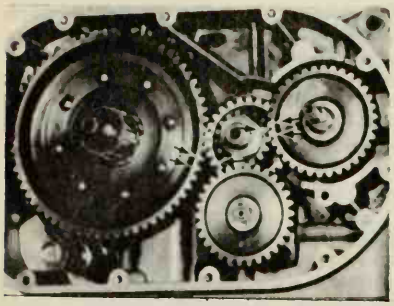
b. Line-ream the camshaft bushings with Camshaft Bushing, and Shifter Cam Left Crankcase Bushing Reamer Set (H-D part no. 97318-61P) or a suitable substitute. The pilot can be mounted on the camshaft support.

5. Inspect the tappets and their bushings for a worn or damaged condition, or for play in excess of the specified 0.0002–0.0005 in. clearance. If the tappets are worn on the cam follower faces, they must be replaced. Ideally the tappets and their bushings should be replaced as sets although individual replacement components are available. Check the bushings for excessive wear by inserting a new tappet and then checking the play.
6. Tappet bushings must also be replaced if loose in the case. The bushings are a press fit and are pressed from the outside of the case with a shouldered, .472 in. (12 mm) drift. Heat the case with a blow torch around the bushing to aid in the removal and replacement process if necessary.
7. Inspect the support bearing for a worn or damaged condition, for excessive side or radial play, or for rough motion and replace as necessary by pressing from the outside of the cover (1969 and later models) with a suitable drift or a block of wood.
8. Inspect the pinion shaft bushing for a worn or damaged condition and replace in the following manner:



a. Remove the bushing with Bushing and Bearing Puller (H-D part no. 95760-69 or 96729-63) or a suitable substitute, and a 2 in. length of pipe with a ⅞ in. inside diameter as a support sleeve.

b. Press the new bushing into the camshaft support or cover and install the cover or support on the right crankcase but do not secure the mounting screws or nuts as yet.



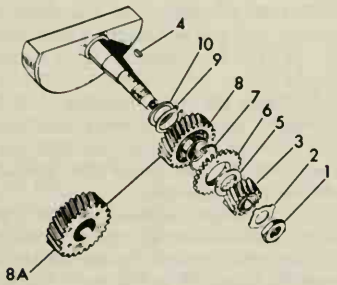
c. Line-ream the bushing with a suitably sized reamer and pilot which can be inserted through the crankshaft ball bearing mounted in the case. Once the reamer is installed securely, tighten the support or cover and ream the bushing using a tap holder if the reamer is not equipped with a handle.

Installation

1. Lightly oil the tappets with clean engine oil and slip them into the appropriate tappet bushing.
2. Install the crankshaft assembly in the crankcase bushing, taking care to align the cam gear timing mark with the pinion gear timing mark.
3. Place the cam gear thrust washer and support assembly onto the camshaft (1968 and earlier models), then tap the support assembly into place by placing a piece of tubing or a socket on the support bearing inner race.

Aligning the timing marks (1968 and earlier models).

Aligning the timing marks (1969 and later models).



4. Install the locks and nuts to secure the assembly.

5. Install the gearcase cover as described in the "Gearcase Cover Removal and Installation" section.

PINION AND DRIVE GEARS

Removal (1968 and Earlier Models)

1. Remove the gearcase cover as described in "Gearcase Cover Removal and Installation."

1. Nut
2. Lock
3. Pinian gear
4. Key
5. Thrust washer, early 1961
6. Drive takeup gear, early 1961

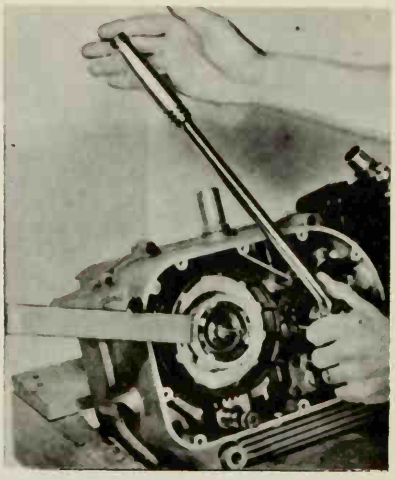
8. Clutch drive gear, early 1961
8A. Clutch drive gear, late 1961 to 1968
9. Lock ring
10. Spacer washer (variable number)

Pinion gear assembly.

2. Remove the assemblies covered in the "Camshaft and Tappets" section.

3. Remove the clutch plates assembly as described in the "Clutch" section.

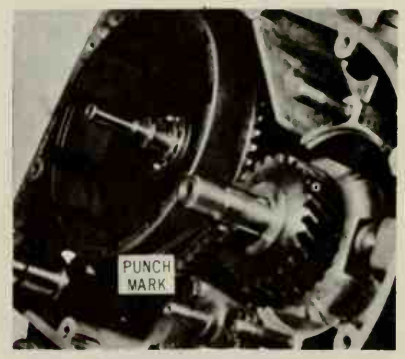


4. Remove the oil pump drive gear as described in the "Lubrication" section.

5. Remove the pinion shaft nut in the following manner:

a. Assemble the Clutch Lock Tool (H-D part no. 97175-61P), or some other means of securing the clutch—such as jamming a wooden door stop between the clutch gear teeth and the crankcase—to the clutch shell to prevent the pinion shaft from rotating while the shaft nut is removed.

b. Secure the clutch hub with Hub Holding Tool (H-D part no. 97291-61PA), or a suitable substitute, and secure the wrench by placing a bolt in the crankcase mounting stud hole as illustrated in the accompanying illustration.



c. Remove the pinion shaft nut with a suitable socket wrench, then remove the lock.

Marking the correct keyway.

Removing the clutch drive gear.

6. Remove the clutch shell and gear assembly as described in the "Clutch" section.

7. Pull the pinion gear free with Two-Jaw Puller (H-D part no. 97292-61P) or a suitable substitute.

8. Mark the keyway in which the key is mounted (there are three keyways but only one takes a key) with a small punch mark, and then remove the key.

9. Remove the thrust washer, drive take-up gear, and the take-up gear spring (if applicable).

10. Secure the clutch hub with Hub Holding Tool (H-D part no. 97291-61PA), or a suitable substitute, then pull the clutch drive gear free with Drive Gear Puller (H-D part no. 97294-61P) or a suitable substitute.

Removal (1969 and Later Models)

1. Remove the clutch assembly as described in the "Clutch" section (1969 and later models).

2. Remove the gearcase cover as described in the "Gearcase Cover Removal and Installation" section.

3. Remove the camshaft thrust washer and camshaft as described in the "Camshaft and Tappets" section.

4. Remove the oil pump drive gear as described in the "Lubrication" section.

5. Remove the pinion shaft nut in the following manner:

a. Disassemble the top end as described in the "Top End" section.

b. Slip a cross-shaft through the connecting rod piston pin hole to freeze the motion of the engine.

c. Remove the pinion shaft wrench with a suitable socket wrench then remove the nut lock.

6. Pull the pinion gear free with Two-Jaw Puller (H-D part no. 97292-61P) or a suitable substitute.

7. Mark and remove the key as directed in the 1968 and earlier models "Removal" section.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect all gears for a worn or damaged condition and replace as necessary. If the clutch drive or pinion gears are replaced, those gears with which they mesh must also be replaced.

3. Inspect the take-up spring for a worn, collapsed, or damaged condition, and replace as necessary.

4. Inspect the thrust washer (if applicable) for a worn or damaged condition which would indicate that the clutch drive gear is slipping on the pinion shaft and that the pinion shaft or the gear or both are in need of replacement. Replace the thrust washer if necessary.

5. Inspect the pinion shaft and gear for a worn or damaged condition and replace as necessary by consulting the "Crankcase" section.

Installation (All Models)

1. Replace the spacer washers, spring washers, and the lockring, with the spring washers between the pinion shaft bearing mounted in the crankcase, and the primary

drive gear. The dished outer diameters of the washers should face each other, and therefore reduce the crankshaft end-play to nothing.

2. Inspect the tapers on the pinion shaft and drive gear for a clean, burr-free condition before going any further.

3. Install the drive gear on the pinion shaft, slip the drive take-up gear spring over the shaft so it seats in the gear, slip the take-up gear on the shaft, and slip the thrust washer in place (1968 and earlier models).

4. Insert a new pinion shaft key in the marked keyway. If the mark has been obliterated or if you have failed to correctly mark the appropriate keyway, do the following:

a. Situate the pinion shaft flywheel so the piston is at TDC (or so the crank pin is).

b. Insert the key in the forward (top center) keyway for 1963 and earlier, and 1969 and later models.

c. Insert the key in the bottom (seven o'clock) keyway for 1964–68 models.

d. Insert the key in any keyway which has been designated by a grind mark on the face of the gear at one of the keyway positions.

5. Install the pinion gear with the timing mark in the forward position as indicated in the illustration in the camshaft and tappet "Installation" section, then mount and secure the lock and nut to finger-tightness. If the lock is new, one tab may be bent up to engage the groove on the gear. The valve timing is controlled by the proper positioning of the gear and key and must be as shown in the following chart.

		Crank Angle		
	Year	Opens	Closes	Lift (in.)
Intake Valve	1973–74	36° BTDC	58° ABDC	0.380
	1969–72	36° BTDC	67° ABDC	0.361
	1967 and later	13° BTDC	50° ABDC	0.296
	1966	15° BBDC	45° ABDC	0.296
Exhaust Valve	1973–74	68° BBDC	24° ATDC	0.370
	1969–72	70° BBDC	20° ATDC	3.50
	1967 and later	54° BBDC	9° ATDC	0.292
	1966 and earlier	55° BBDC	4° ATDC	0.292

6. Complete assembly in the following manner for all 1968 and earlier models:

a. Install the clutch shell gear and hub using Clutch Lock Tool (H-D part no. 97175-61P) or an alternative method as described in the "Removal" section. Secure the clutch hub with Clutch Hub Holding Tool (H-D part no. 97291-61PA), or a suitable substitute, and block the handle with a bolt inserted in one of the crankcase holes. Using a suitable wrench, secure the pinion gear nut to 35 ft lbs torque, then complete the clutch assembly procedures as described in the "Clutch" section.

b. Install the oil pump drive gear as described in the "Lubrication" section.

c. Install the cam gear and support plate as described in the "Camshaft and Tappets Assembly" section.

d. Install the gearcase cover as described in the "Gearcase Cover Removal and Installation" section.

7. Complete assembly in the following manner for all 1969 and later models:

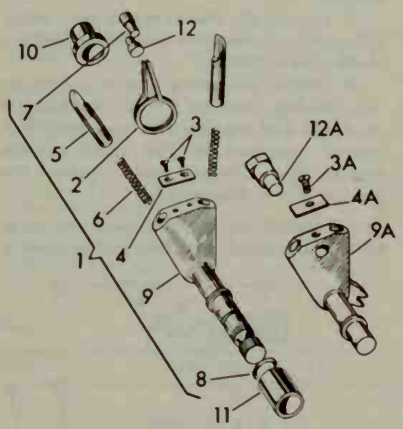
a. Freeze the motion of the engine by inserting a rod through the connecting rod piston pin hole, then secure the pinion gear nut to 35 ft lbs torque.

b. Install the oil pump drive gear, camshaft, camshaft thrust washer, and the primary drive gear as described in their respective sections.

c. Complete the clutch assembly procedures as described in the "Clutch" section.

d. Install the gearcase cover as described in the "Gearcase Cover Removal and Inspection" section.

SHIFTER PAWL CARRIER



Disassembly

1. Remove the gearcase cover as described in the "Gearcase Cover Removal and Inspection" section.

2. Remove the clutch assembly on 1968 and earlier models as described in the "Clutch" section.

3. Remove the shifter pawl carrier thrust washer.

4. Remove the assembled shifter pawl carrier assembly from the case, then remove the return spring from the assembly.

11. Caver carrier shaft bushing (1972 & earlier)
12. Return spring pin (1972 & earlier)
12A. Return spring pin (1973 & later)

Shifter pawl carrier assembly.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

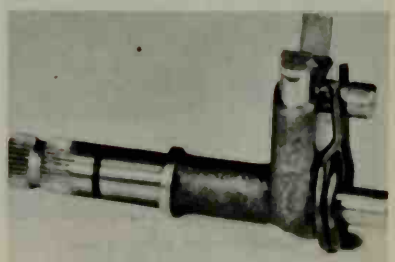
2. Inspect the pawls for a worn, grooved, cracked, or damaged condition and replace them as necessary.

3. Inspect the pawl springs for a collapsed or damaged condition and replace as necessary. The springs must be replaced if they are less than 1½ in. long.

4. Insert the springs and pawls into the carrier and check their motion for smooth and free operation. If the springs and pawls are in good condition and the motion is rough, replace the carrier. If the carrier is worn or damaged on its other surfaces, it must then be replaced also.

5. Inspect the crankcase carrier shaft bushing for a worn or damaged condition and replace as necessary by removing the engine from the frame as directed in the engine "Removal and Inspection" section and then separating the crankcase halves as directed in the "Crankcase" section. The bushing may then be pressed out from the inside with a suitable, shouldered drift, and then pressed in from the outside with the same drift.

6. Inspect the shifter carrier rubber O-ring for a cracked or damaged condition and replace as necessary.



7. Inspect the cover carrier shaft bushing for a worn or damaged condition and replace as necessary by pressing it out from the inside of the cover with a suitable, shouldered drift and then back in with the chamfered side first until flush with the bushing boss.

Assembly

1. Insert the pawl springs into the pawls, and then slip the pawls and springs into the carrier so the flat portions of the pawls face each other.

2. Install the retainer plate and secure it with the plate screws while holding the pawls down.

3. Press new stop pins into place in the carrier so that the flat portions of the pins are parallel with the retainer plate.

Shifter pawl carrier with the spring mounted.

Positioning the carrier assembly in the crankcase.

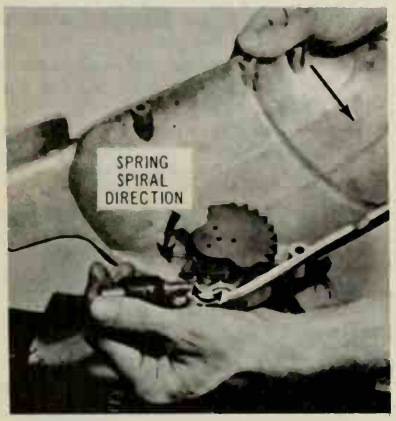
4. Assemble the return spring to the assembly so the offset portion of the spring is toward the crankcase, and so the stop pin is between the spring arms.

5. Slip the rubber O-ring into position in its groove in the carrier shaft.

6. Install the carrier in the crankcase and engage the return spring on its pin as illustrated. If the spring is properly engaged the shaft will not be able to turn.

7. Install the clutch assembly on 1968 and earlier models as described in the "Clutch" section.

8. Install the gearcase cover as described in the "Gearcase Cover Removal and Installation" section.



Kick-Starter

DISASSEMBLY

1. Remove the left side cover screws and remove the cover by tapping on its sides with a soft mallet while pulling on the starter crank.

2. Remove the starter crank nut, bolt, the crank and pedal assembly, and the crank clevis (if applicable).

3. Remove the crank gear shaft support bolts, washers, and the support, then remove the stop stud acorn nut and washer (1971 and later models).

Removing the crank gear stop stud.

4. Secure the crank gear's shaft in a wood or copper-jawed vise, then rotate the cover to relieve the spring tension while removing the crank gear stop bumper and stud from the cover.

5. Carefully release the spring tension and remove the cover assembly from the vise.

6. Remove the crank gear and the starter spring from the cover.

7. Remove the clutch gear lockring, using snap-ring pliers, or press the clutch against the clutch spring and pry the outer ring free (late 1970 models).

8. Remove the clutch spring collar, spring, clutch, clutch gear assembly, and the gear lockring. Carefully examine the illustration since there are discrepancies in the order of assembly for the 1969 and later models.

INSPECTION

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect the crank gear, clutch, and the clutch gear assembly for wear, damage, or chipped or battered teeth, and replace them as a set if necessary. Crank gears since late 1961 have had 10 teeth rather than eight, and replacement should be with the newer variety.

3. Inspect the clutch gear bushing for a worn, loose, or damaged condition and replace it as necessary with a 0.570 in. shouldered drift. This bushing will not need to be reamed.

4. Inspect the starter clutch spring for a collapsed or damaged condition and replace it as necessary. The spring must be replaced if it has become shorter than 0.984 in.

5. Inspect the lockrings for a worn, warped, or damaged condition and replace them as necessary.

6. Inspect the crank gear shaft bushings for a worn, excessively loose fit with the core or shaft, or a damaged condition, and replace them as necessary. The bushings may be pressed out with a shouldered drift having a small diameter of 0.669 in. and a large diameter of 0.866 in. When replacing the bushings, press them in until flush with the bushing boss, and so the chamfered side is to the inside of the cover. These bushings will not need to be reamed.

7. Inspect the starter spring for a worn, collapsed, or damaged condition, and replace it as necessary.

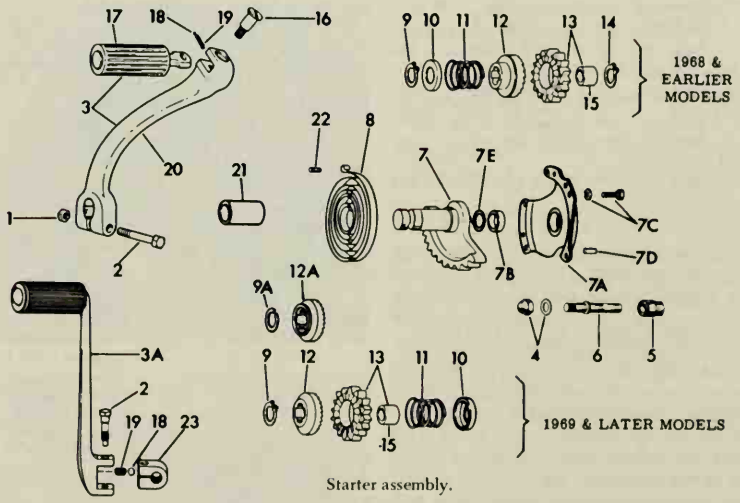
8. Inspect the crank gear stop bumper and the stop stud for a worn or damaged condition and replace it as necessary. Pay special attention to the metal sheath around the bumper and replace the bumper if it is damaged.

9. Inspect the spring dowel pin for a worn or damaged condition and remove it only if replacement is necessary. The pin is a press fit into the cover.

10. Rotate the crank pedal in both directions and check to see if it locks in both extreme positions. If it fails to lock, the pedal spring should be replaced.

ASSEMBLY

1. Assemble parts to the mainshaft in the reverse order of disassembly. The clutch gear bushing is pressed into the gear.



2. Position the starter spring on the crank gear so the spring is wound counterclockwise from the center when viewed from the cover side.

3. Install the crank gear in the gear shaft cover bushing, taking care to secure the loop of the spring on the spring dowel pin.

4. Secure the crank gear shaft in a wood or copper-jawed vise, rotate the cover until the spring is properly tensioned, unwind the cover 1–1½ turns, and then mount the crank gear stop stud and bumper to the cover. Remove the cover assembly from the vise, and secure the stop stud acorn and washer.

5. Secure the crank gear shaft support assembly (if applicable).

6. Assemble the crank and pedal assembly or the crank clevis and then the crank and pedal assembly (if applicable). Before securing the assembly with the crank bolt and nut, and the cover to the crankcase, make sure the crank is so positioned on the shaft splines as to allow the crank to be operated without smashing your shin or the crank against the footrest while kicking the engine over.

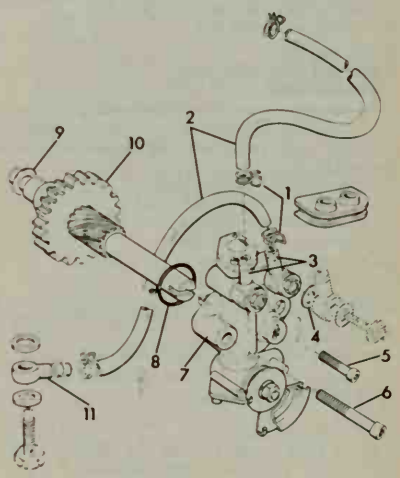
OIL INJECTED MODELS

Oil Pump

REMOVAL



1. Disconnect the oil pump cable from the control lever on the pump.
2. Loosen the oil line clamps and move them back on the oil lines. Disconnect the oil line from the pump fittings. Note to which fitting each oil line is connected to so they will not be reversed upon installation.

CAUTION: *If for any reason the banjo fittings are removed the aluminum washers on either side of the fittings must be replaced with new items.*

3. Remove the two mounting screws, and pull off the oil pump. The O-ring behind the oil pump should be replaced every time the oil pump is removed.

INSTALLATION

1. Mount the oil pump to the engine with the two mounting bolts. Use a new O-ring behind the pump.
2. Connect the oil line to the pump, and reposition the clamps.
3. Bleed the oil pump. Connect the oil pump cable, and adjust it.

Bleeding the Oil Pump

1. Disconnect the oil line from the fitting on the manifold. Do not remove the fitting.
2. Drain the gas tank of gas, and fill with a gas/oil mixture of 50/1 for the SS/SX 175/250 or 25/1 for the other models.
3. Make sure that the oil tank is filled with H-D "Two-cycle Lubricant."
4. Start the engine and allow it to idle. Hold the oil pump control lever in the wide open position until the oil coming from

Oil Pump Cable Adjustment

1. Adjust the oil pump cable after adjusting the throttle cable.

2. Remove the oil pump cover.

3. With the throttle held in the wide open position the maximum flow mark on the pump control lever should align with the index mark on the body. If the marks do not align, use the cable adjuster to adjust the cable so that they do.

SPRINT MODELS

The Sprint employs a pressure-fed oil pump which forces the oil to circulate through and lubricate the lower end connecting rod, camshaft, rocker arm bearings, and the valve train, while the excess oil which is thrown off the connecting rod and crankshaft splash lubricates the cylinder assembly, the main bearings, and the transmission. The gearcase is kept well-oiled by the oil which drains down from the cylinder head through the push rod housing, and the remaining oil from the head drains into the crankcase through the exhaust rocker arm cover and oil return pipe.

There are two scavenger methods employed to return the oil into circulation once it has reached the crankcase. On 1963 and earlier models, the oil is passed from the scavenger pocket through a filter by the action of a duplex oil pump which then forces the oil through the pump body and into the gearcase. The oil then returns to the crankcase for recycling by passing through a gap between the two compartments as it attempts to seek its own level.

On the 1964 and later models, the oil drains directly into the crankcase sump where it is picked up for recirculation by an inlet pipe in the center of the feed pump filter.

OIL PUMP

Disassembly

1. Drain all the engine oil as described in "Maintenance".

2. Remove the gearcase cover as described in the "Gearcase" section and plug up all the openings into the crankcase.

3. On 1968 and earlier models remove the camshaft support assembly as described in the "Gearcase" section.

4. Remove the drive gear locknut and lock while holding the pinion gear steady.

5. Remove the drive gear using Two-Jaw Puller (H-D part no. 97292-61P) and Cap (H-D part no. 95652-43A), or suitable substitutes, taking care not to damage the threads that the cap protects.

6. Remove the scavenger line connection and both washers from 1963 and earlier models.

7. Remove the pump bolts and locks, then remove the entire pump assembly from the gearcase.

8. Remove the scavenger line and gasket from 1963 and earlier models.

9. Remove the inner and outer covers, the upper gear (when looking at the pump body from the outer cover side), the feed idler gear, the feed driving gear key and gear, and the idler gear.

10. Remove the O-ring from the inner cover, inspect the dowel pins for a worn or damaged condition, and remove them only if necessary.

Inspection

1. Clean all the parts in a suitable solvent and blow them dry, remembering to blow all the oil passages clear.

2. Inspect all the gears for a worn or damaged condition and replace them as necessary. Gears should be replaced in sets.

3. Inspect the remaining components for a worn or damaged condition and replace them as necessary.

Assembly

1. Assembly is basically the reverse order of disassembly.

2. Lightly oil all moving parts with clean engine oil before assembling them.

3. Press the new dowel pins into the pump body (if applicable).

4. Proceed in the following manner for all 1963 and earlier models:

a. Slip the upper gear and idler gear shafts into the upper hole on the outer cover side of the pump body.

b. Assemble the feed gear and key onto the idler gear shaft, and the feed idler gear shaft onto the scavenger gear shaft.

c. Assemble the inner and outer covers onto the pump body, then install the O-ring to the inner cover.

d. Position the scavenger line gasket then install the scavenger line.

e. Place the oil pump into position in the crankcase, making sure that the O-ring remains in position in the inner cover.

f. Hold the copper gaskets in place on either side of the scavenger line and assemble the scavenger line connection to the pump body without securing it.

g. Install the pump body bolts and new locks, then tighten them finger-tight before securing them in diagonal pairs.

5. Proceed in the following manner for all 1964 and later models:

a. Insert the upper and idler gear shafts into the outer cover, then position the inner cover over the shafts, taking care to correctly register the dowel pins.

b. Install the O-ring on the inner cover, and mount the pump in the crankcase with the pump body bolts and new locks.

6. Wipe the gear shaft and drive gear tapers clean, then install and secure the drive gear to the shaft with a nut and a new lock. The shaft can be kept from rotating by pressing down on one side of the driving gear.

7. Install the gearcase cover as described in the "Gearcase" section.

FUEL SYSTEMS

NOTE: *For an operational theory, general inspection, and troubleshooting chart, refer to the "Carburetor" section under "General Information."*

CARBURETORS

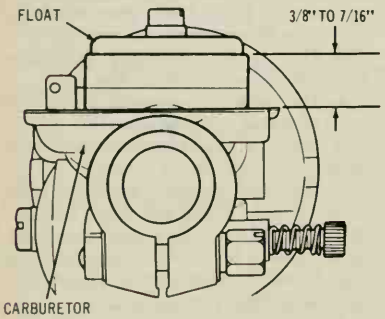
Models M-50 and M-65

DISASSEMBLY (1965 MODEL)

1. Close the petcock and remove the fuel line at the carburetor.

2. Loosen the clamp screw and remove the silencer, clamp, air filter, and the filter gasket.

3. Remove the intake manifold clamp screw and pull and twist the carburetor free of the intake port.



4. Remove the mixing chamber cap screws, close the throttle, compress the throttle slide spring by hand, disengage the throttle cable from the throttle slide, then remove the pivot pin and the choke control lever and spring.

5. Remove the pivot screw and choke return spring, then remove the choke plate.

6. Remove the gas strainer cap screw, washer, and the strainer cap.

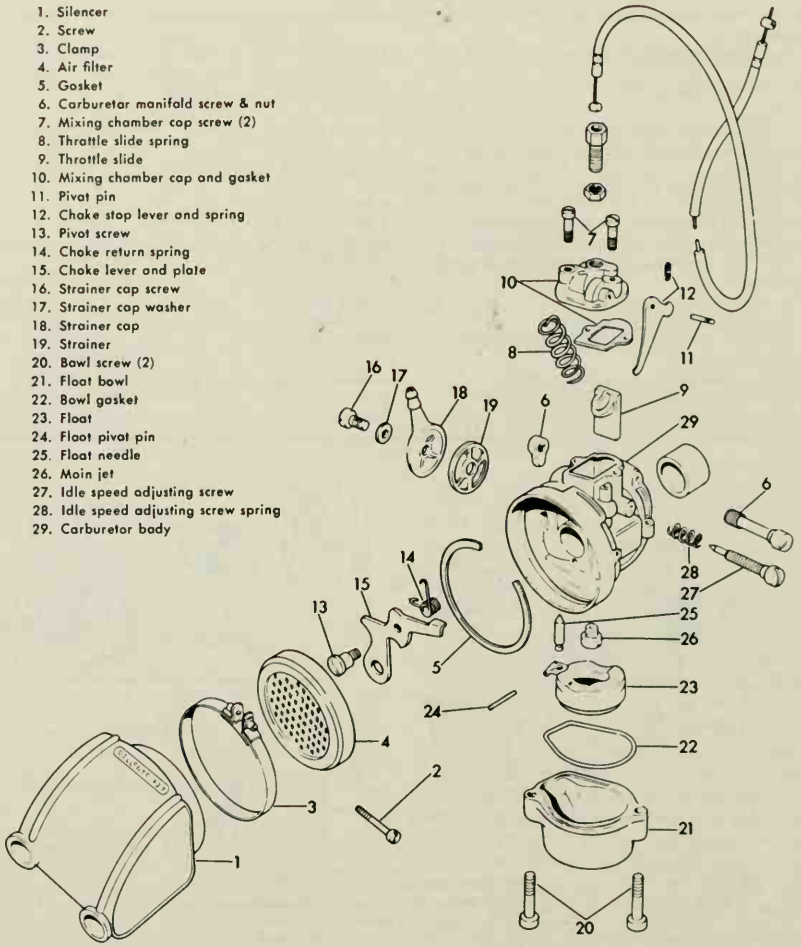
7. Remove the bowl cover screw, bowl, and bowl gasket. The float can now be removed by first removing the float lever pin and float needle.

8. Unscrew the main jet, then remove the idle speed adjusting screw and spring.

Checking the float level, M-50 and M-65.

DISASSEMBLY (1966 AND LATER MODELS)

1. Close the petcock and remove the fuel line at the carburetor.



2. Remove the silencer mounting screw, silencer, spacer and spring, air filter, and the silencer gasket but only if inspection of the gasket indicates that it should be replaced.

3. Loosen the manifold clamp screw and pull and twist on the carburetor until free.

4. Loosen the mixing chamber cap screws and pull the cap and throttle slide assembly free of the carburetor body.

5. Close the throttle, compress the throttle slide spring by hand, disengage the throttle cable from the slide fastener, unscrew the fastener from the slide, and remove the needle and retainer clip.

6. Remove the choke plate from the choke pin, push out the choke pin retainer clip, and remove the pin and pin spring.

7. Inspect the throttle cable adjusting screw and nut, and remove and replace them only if necessary.

8. Remove the gas strainer cap screw, cover, large and small strainer gaskets, strainer, bowl cover screws and washers, and then separate the cover from the gasket.

9. Remove the float retainer clip, float pin, pin spring, and float.

10. Unscrew the needle jet plug, remove the plug gasket, and remove the main nozzle.

11. Remove the pilot jet, main jet carrier, main jet, idle-speed adjusting screw and spring, throttle slide adjusting screw and spring, and the insulating bushing, only if it requires replacement.

ASSEMBLY

1. Assembly is basically the reverse order of disassembly with the following exceptions, which pertain to the 1965 model:

a. Position the float needle in the carburetor body, then insert the pivot pin

b. Hold the carburetor so the float is up and resting on the float pin, then measure the distance from the float's top ridge to the bowl seat.

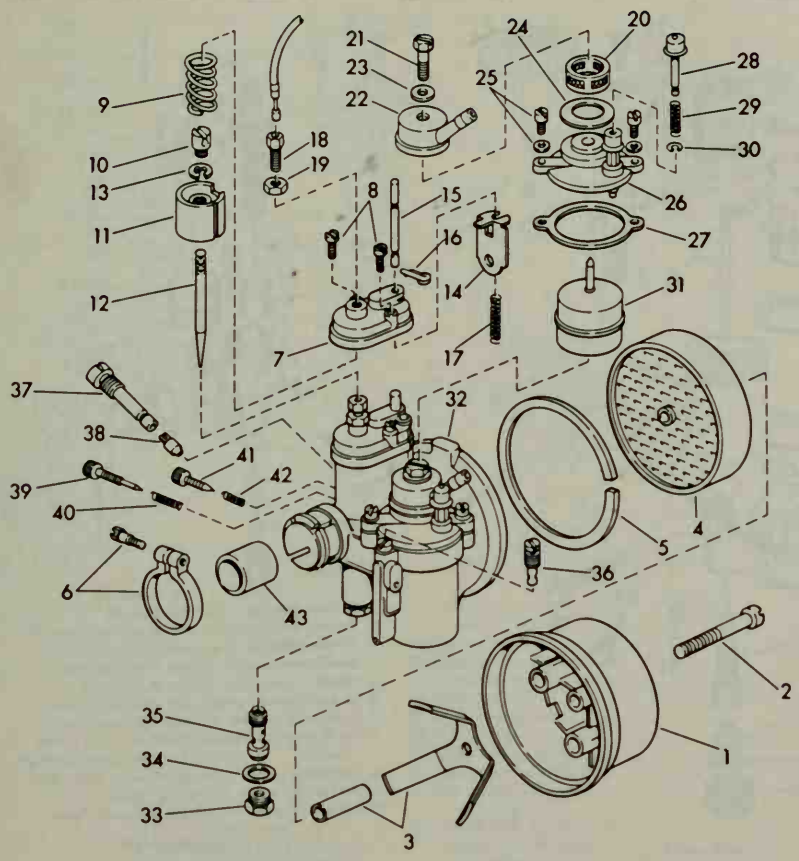
c. If the above measurement is not within $\frac{3}{8}$–$\frac{7}{16}$ in., the situation may be corrected by carefully bending the float tang slightly. If this doesn't correct the problem, the float or the needle or both may be damaged and in need of replacement.

2. Open the throttle and engage the cable sheath in the piston cap and the cable itself to the piston body, and then mount the piston cap on the carburetor body.

3. Install the carburetor on the intake manifold.

4. Adjust the throttle cable as described in the "Tune-Up" section.

5. Mount and secure the air cleaner and silencer assemblies.



6. Connect the fuel line to the carburetor and fuel tank.

7. Adjust the carburetor as described in the "Tune-Up" section.

2. Close the petcock and disconnect the fuel line at the carburetor.

3. Close the throttle, depress the choke, unscrew the mixing chamber cap nut, and pull the throttle assembly free of the carburetor body.

4. With the throttle closed, compress the throttle slide spring, disengage the throttle cable from the slide, remove the needle retainer clip, needle, and the throttle slide spring.

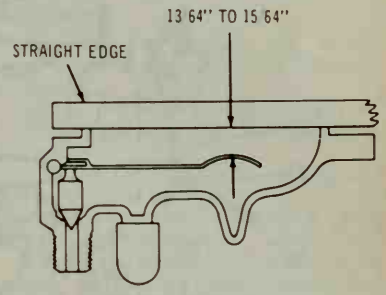
5. Inspect the cable adjusting screw, nut, and the choke rod hair pin spring and remove them only if they are in need of replacement.

6. Remove the gas strainer cap, gas line fitting, strainer gaskets, strainer. bowl cover screws and washers, and carefully pull the bowl straight down and away from the carburetor body.

7. Remove the bowl gasket, the float, float lever pivot screw, float lever, and the float needle. Remove the float pin lockring from the bowl cover to remove the float pin and spring.

8. Unscrew the jet cap, remove the cap washer, unscrew the main jet, needle jet and the pilot jet.

9. Remove the throttle stop screw and nut, and the pilot air screw and spring.



ASSEMBLY

1. Assembly is basically the reverse order of disassembly, but take note of the following exceptions.

2. Install the pilot jet in the carburetor body before installing the needle and the main jet.

3. Install the float needle in the bowl cover, engage the fingers of the float lever in the slot provided in the neck of the float needle, and insert the pivot screw through the pivot hole in the end of the float lever and into the bowl cover.

4. Check the float level in the following manner:

Checking the float level.

a. Invert the bowl cover and lay a straightedge across its face.

b. Measure the distance from the highest point of the float lever to the straightedge. Carefully bend the lever if necessary to bring the measurement within $^{13}/_{64}$–$^{15}/_{64}$ in.

c. If repeated attempts to correct the level fails, either the lever, needle, or float are at fault, and one or more of these items will have to be replaced.

5. Assemble the float pin lockring and the pivot screw, engage the float with the float lever, and mount the assembly in the bowl, taking care to insert the float shaft on the bottom of the float in the hole provided for it in the bottom of the bowl.

6. Assemble the choke rod hairpin spring, cable adjusting nut, cable adjusting screw, and the piston cap nut on the piston cap and choke assembly.

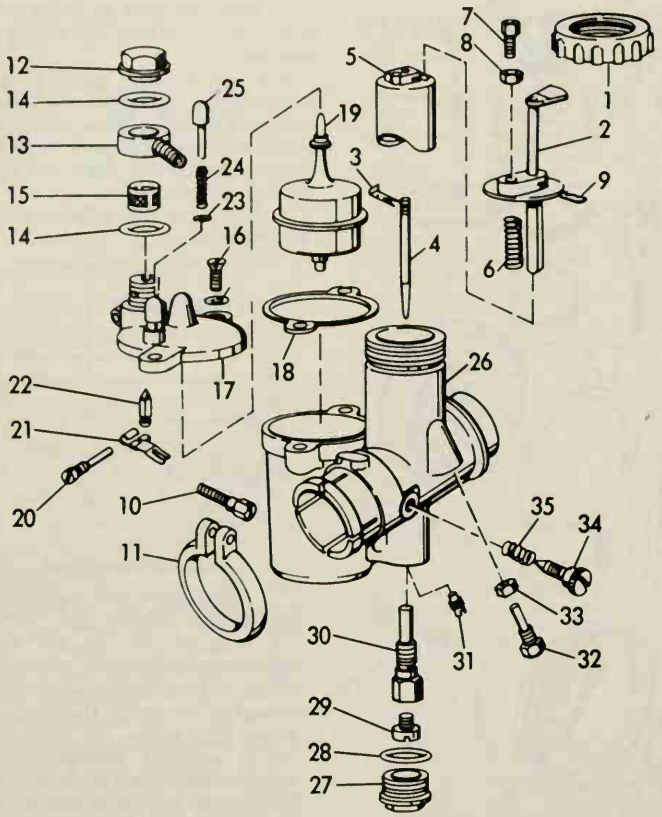
7. Insert the needle in the throttle slide and use the retainer clip to secure the needle in the desired groove. Unless abnormal carburetion is required, use the middle groove.

8. Slip the cable through the adjusting screw, then position the throttle slide spring on the cable.

9. Press down on the choke slide and position the throttle slide assembly on it. The cable can be secured in the slide once the spring is compressed by hand.

10. Mount the carburetor on the intake manifold.

11. Open the throttle handgrip and slip the throttle assembly in place in the carburetor body taking care to align the mixing chamber cap lug with the carburetor notch. Install and secure the mixing chamber cap nut.



12. Mount the fuel line and the air cleaner assembly.

13. Adjust the carburetor as described in the "Tune-Up" section.

2. Shut the petcock and disconnect the fuel line at the carburetor inlet connection.

3. Unscrew the carburetor cap and pull on the throttle cable to remove the slide cap, spring, slide, slide needle retainer, and the needle as an assembly.

4. Close the throttle at the handgrip, squeeze the slide and cap together, and disengage the cable from the slide by carefully prying it free with a small, flat screwdriver. The assembly is now free to be disassembled.

5. Loosen the mounting screw and remove the carburetor body from the intake manifold along with the carburetor gasket, bushing, and insulator.

6. Remove the jet holder, needle jet, and gasket from the bottom of the carburetor body using a suitable socket or open-end wrench only. If inspection indicates the need for replacement or special attention, the main jet can be removed from the holder with a suitably sized screwdriver.

7. Remove the bowl cover screws, cover, float, and also remove the float needle from the float.

8. Inspect the float needle seat. Remove and replace it only if necessary.

9. Remove and replace the float primer cotter pin, and remove the float primer spring, and the primer pin if inspection indicates the need for replacement.

10. The throttle slide guide screw can be removed from the carburetor if so desired.

ASSEMBLY

1. Assembly is basically the reverse order of disassembly, with certain exceptions.

2. Insert the float needle in the float and install the assembly in the float bowl.

3. Mount the bowl cover on the carburetor body so the primer pin is away from the slide cap. The float needle should seat in the needle seat.

4. Position the carburetor gasket, bushing, and insulator on the carburetor body and mount the carburetor to the carburetor mounting flange. The slotted end of the bushing should be up and toward the cylinder.

5. Slip the needle retainer into the proper groove in the needle.

6. Complete the assembly of the throttle components and adjust the carburetor as described in the "Tune-Up" section.

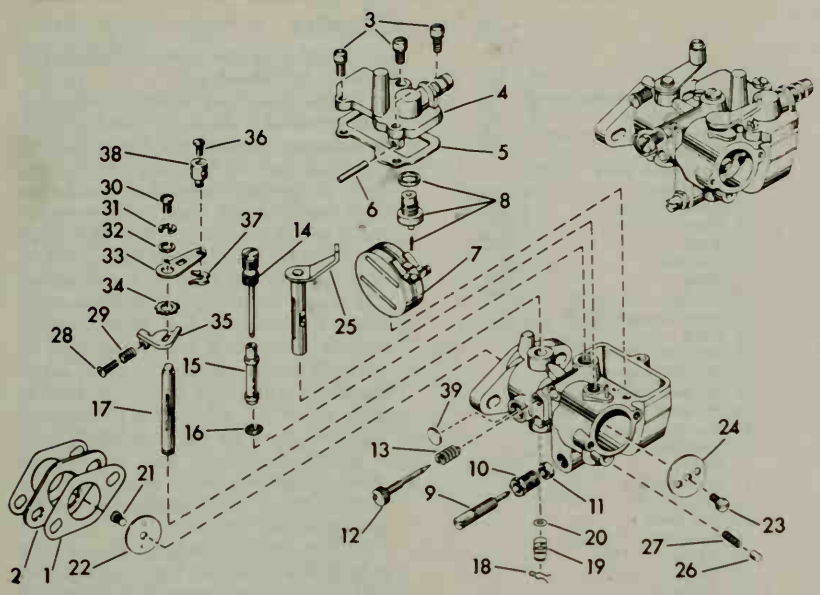
DISASSEMBLY

1. Remove the air cleaner assembly (if applicable), disconnect the throttle cable at the carburetor, shut the petcock, disconnect the fuel line at the carburetor, and remove the carburetor from the cylinder mounting flange.



2. Remove the thin and heavy carburetor-to-cylinder gaskets, the bowl cover screws and lockwashers, and the bowl cover and gasket.

3. Free the float by pressing the float pin free of the cover, then remove the inlet needle, seat, spring, and gasket with a screwdriver that has a thick blade.

4. Unscrew the main adjusting screw and remove the packing nut and packing.

5. Remove the idle adjusting screw, spring, idle tube, nozzle, and the nozzle gasket, which may have to be pried out and replaced.

6. Inspect the throttle shaft and bearing assembly for signs which would indicate

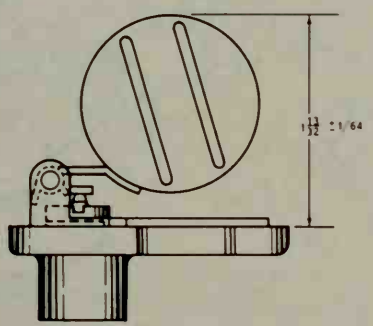
the need for replacement, and remove them if necessary in the following manner:

a. Pry the throttle shaft retaining clip free of its groove on the shaft and remove the shaft spring, seal, shutter screw, and shutter. The shaft is now free to be removed from the carburetor body.

b. If the choke shaft is to be removed, take care not to lose the friction pin and spring by holding your thumb over them while withdrawing the shaft.

INSPECTION



1. Clean all parts other than the gaskets and float in a suitable solvent and blow them dry, taking care to blow all the passages clear. Do not attempt to scrape deposits off with metal instruments.

2. To inspect the idle mixture discharge ports, the welch plug will have to be removed by carefully punching a small, shallow hole in the plug at a point near the rim, and then prying the plug free. When installing a new plug, do so with a suitably sized drift, taking care to make it a tight fit.

3. Inspect all the parts for a worn, scored, or otherwise damaged condition, and replace them as necessary. If the tip of the inlet needle is not in good condition, the fuel level will not be correct. If the throttle or choke shaft bearings are worn or damaged, air leakage will occur which causes rough idling.

4. Inspect the gaskets and float for a worn, damaged, or gas-logged condition, and replace them as necessary.

5. Check the float level in the following manner:

Checking the float level, B Models.

a. Assemble the float lever pin, float, inlet needle, spring, seat, and gasket to the bowl cover.

b. Invert the float bowl so the lever tang rests on the seated inlet needle.

c. Measure the distance from the edge of the cover (without the cover gasket) to the top of the float with a straightedge ruler or a depth gauge.

d. Correct the measurement to $1\frac{13}{32}$ in. if necessary by removing the lever pin and carefully bending the float tang as required. Bend the tang evenly so the float sits squarely in the bowl.

ASSEMBLY

1. Assembly is basically the reverse order of disassembly, with the following exceptions.

2. Make sure the idle tube is securely tightened down during the installation procedure.

3. Check the float for free-motion and the correct level.

4. Secure the throttle shutter to the shaft after the spring and clip are installed.

5. Insert the friction spring and then the friction pin into the choke channel and hold them temporarily in place with a daub of grease, a match, or any suitable device which will hold them while the choke shaft is moved into place.

6. Place a thin gasket on either side of the thick gasket when mounting the carburetor on the cylinder mounting flange.

7. Complete the assembly procedure and adjust the carburetor as described in the "Tune-Up" section.

X-90, Z-90, SR-100, TX/SX 125

DISASSEMBLY

1. Turn the fuel petcock to the off position, and disconnect the fuel line from the petcock.

2. Remove the air cleaner and the air cleaner housing.

3. Loosen the intake manifold clamp, and using a twisting motion pull the carburetor off from the rear.

4. Remove the two screws from the carburetor cover, and remove the cover and slide assembly.

5. Disconnect the throttle cable from the throttle slide. Remove the throttle slide, return spring, cover gasket, and carburetor cover from the cable.

6. Remove the screw from the center of the inlet fitting and the gasket beneath it. Remove the inlet fitting, fitting gasket, and fuel filter screen.

7. Remove the choke valve assembly and the O-ring beneath it.

8. Remove two float bowl screws, and remove the float bowl and gasket.

9. Remove the float pivot pin. Withdraw the float, and the float needle.

10. Remove the main jet, needle jet, pilot jet, and the starter jet.

11. Remove the idle speed and idle mixture adjusting screws and their springs.

Carburetor assembly, X-90, Z-90, SR-100, TX/SX-125

ASSEMBLY

1. Assembly is the reverse of disassembly, note the following:

a. The float level should be checked and corrected if necessary. The float level is measured between the top of each of the floats and the float bowl mating surface of the carburetor body with the float needle seated. The correct measurement is 0.925–0.965 in. (23.5–24.5 mm) for 175 models or 0.689–0.728 in. (17.5–18.5 mm) for 250 models. A special tool (H-D part no. 97362-74P) is made especially to check the float level on these models although a short steel rule or veriner claipers can also be used. If the float level is incorrect, bend only the float tang to correct adjustment. Make sure that both floats are the same height.

b. Slip the needle into the throttle slide, and engage the retainer clip in the desired groove of the needle. The middle groove is used normally.

c. Run the throttle cable through the rubber boot, adjusting screw, and throttle slide spring, then compress the spring by hand and insert the cable into the throttle slide. When installing the throttle slide into the carburetor bore be sure that the cutaway portion of the slide is facing the air cleaner.

2. Remove the air filter assembly.

3. Loosen the intake manifold clamp and using a twisting motion pull the carburetor off from the rear.

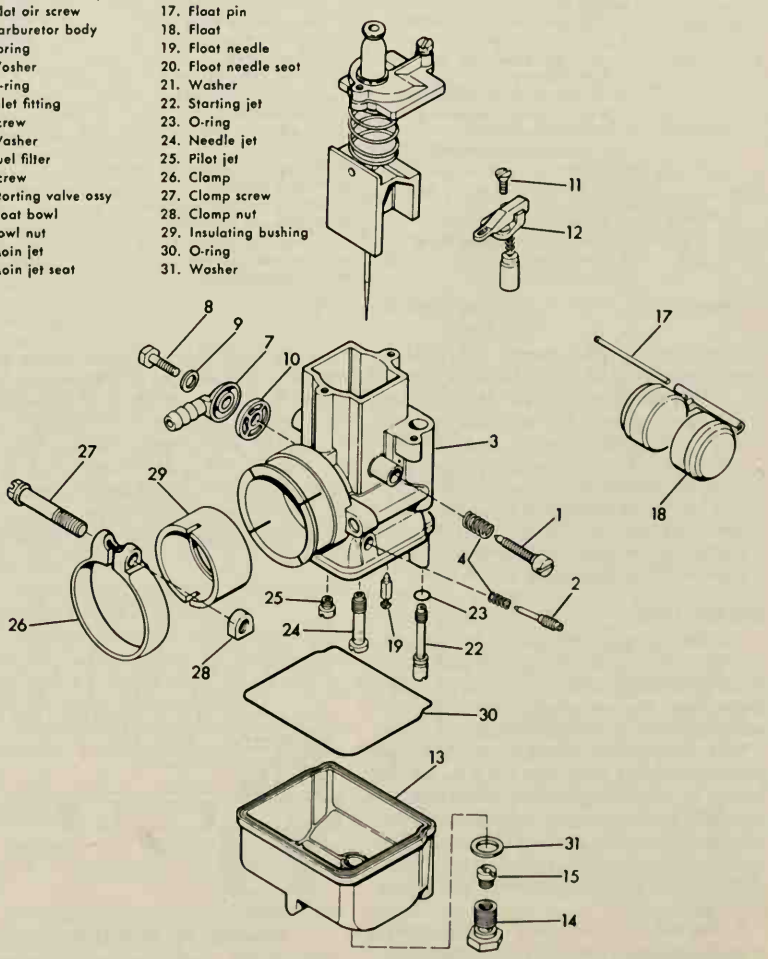
4. Remove the two screws from the carburetor cover, and remove the cover along with the slide assembly.

5. If the slide assembly is not in need of servicing, it may be placed in a plastic bag secured around the throttle cable with a rubber band, and placed out of the way. If the slide is to be disassembled, disengage the cable from the slide and remove the slide, return spring, and carburetor cover from the cable. The needle can be removed from the slide if necessary. If the needle is removed be sure to note which groove the retainer clip was located in so that it can be installed in the same groove unless tuning changes have been made.

6. Remove the screw from the center of the inlet fitting and the gasket beneath the screw. Remove the inlet fitting and the filter screen beneath it.

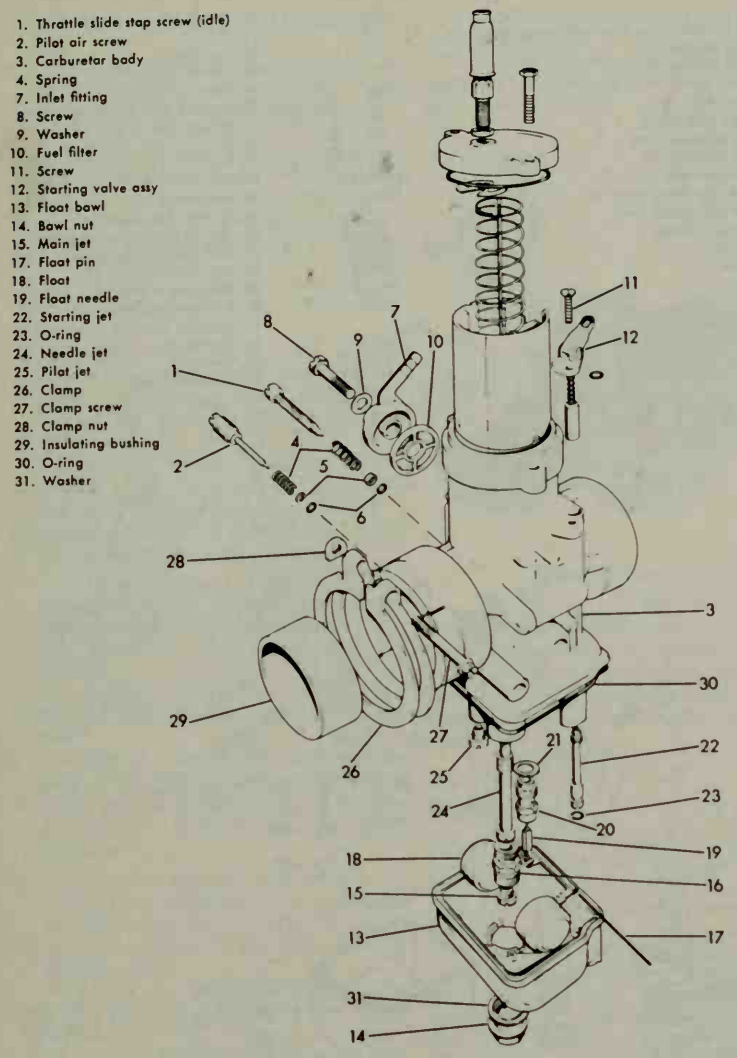
7. Remove the idle speed and idle mixture adjusting screws and the spring behind them. On some models there is a washer and a O-ring behind the screws, take care that if fitted they are not lost.

8. Remove the retaining screw, and pull the choke assembly from the carburetor.



9. Remove the nut from the bottom of the float bowl. On SS/SX 175 models the main jet is removed with this nut. Remove the float bowl.

10. On SS/SX 250; remove the main jet and the main jet holder.



11. Remove the float pivot pin, and remove the float and the float needle. On SS/SX 250 models, unscrew the float needle seat and remove the washer beneath it.

12. Remove the starting jet, needle jet, and the pilot jet.

DISASSEMBLY

1. Remove the gas tank on 1967 and later models, then remove the air filter assembly or the hose.

2. Shut the petcock, disconnect the fuel line at the carburetor, push down on the choke (if applicable), open the throttle handgrip, slide the rubber boot up the cable, unscrew the mixing chamber cap or cap screws and washers, and pull the throttle assembly from the carburetor body.

3. Loosen the intake pipe clamp screw and pull and twist the carburetor from the manifold.

4. Disassemble the throttle assembly in the following manner:

a. Close the throttle at the handgrip and remove the throttle cable from the throttle slide while compressing the spring by hand.

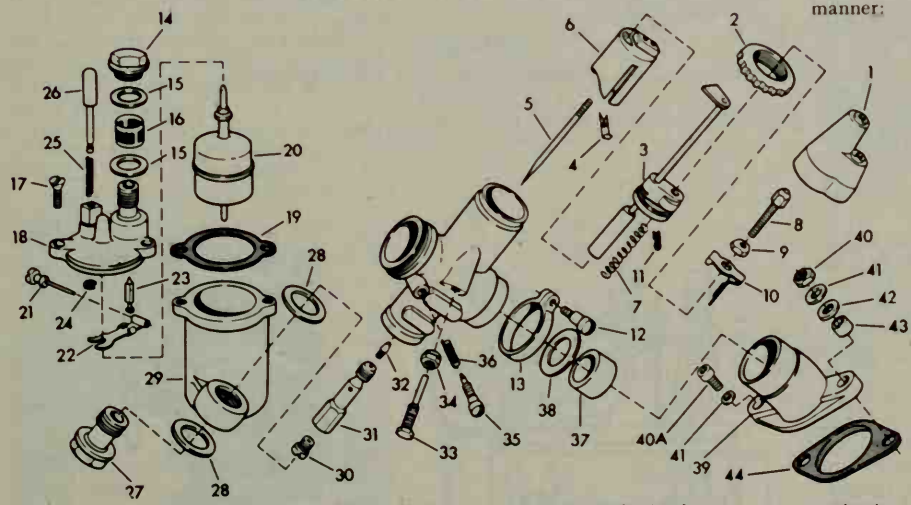
b. Remove the needle retaining clip and needle from the throttle slide, then remove the throttle spring from the slide.

c. Remove the cable adjusting screw, nut, friction spring, and the choke rod rod hairpin spring if so desired.

5. Disassemble the float bowl assembly on 1968 and earlier models in the following manner:

a. Remove the gas strainer cap, gaskets, and the strainer.

b. Remove the bowl cover screws and also the cover and gasket.



c. Remove the float, float lever pivot screw, lever, and float valve.

d. Remove the float pin lockring, then remove the float pin and spring.

e. Remove the bowl connection cap, bowl, and the fiber washers.

6. Disassemble the 1969 and later-model float bowl by removing the bowl nut, the main jet, and the nut gasket, then remove the bowl and the O-ring gasket.

7. Disassemble the carburetor body on 1968 and earlier models in the following manner:

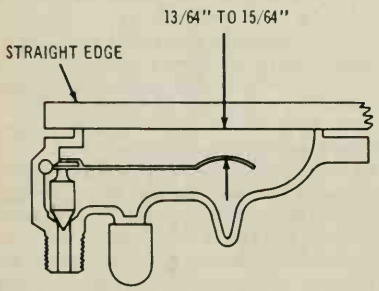
a. Remove the main jet, needle jet, and the pilot jet.

b. Remove the throttle slide stop screw, nut, pilot air screw, spring, and the insulating bushing and washer.

8. Disassemble the 1969 and later-model carburetor in the following manner:

a. Remove the float lever pivot pin, float, and the float needle.

b. Remove the needle jet, pilot and starting jets, starting jet O-ring, starting valve and lever assembly screw, assembly, inlet fitting screw, washer, fitting, and inlet screen.



c. Remove the throttle slide stop-screw, the pilot air screw, and their respective springs.

ASSEMBLY

Assembly is basically the reverse order of disassembly with the following exceptions:

1. Install the pilot jet, needle jet, and the main jet, in that order, on 1968 and earlier models.

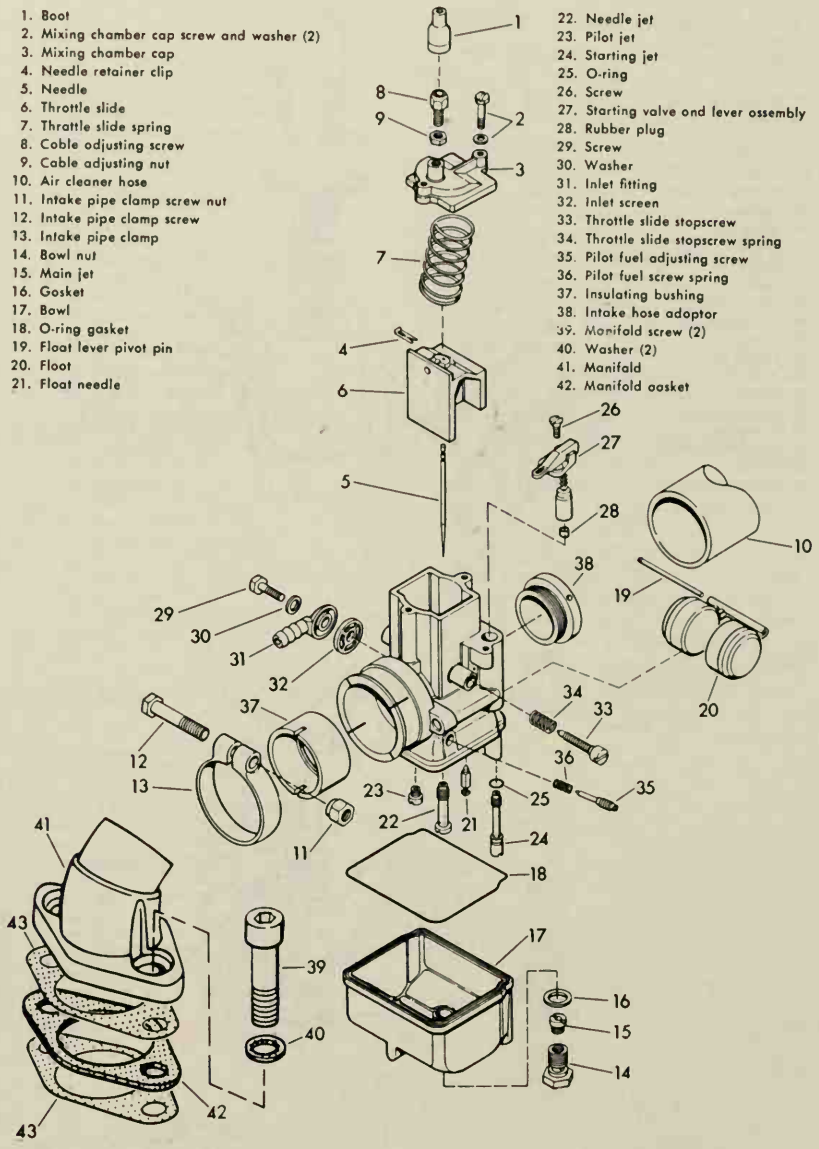
2. Insert the float needle into the bowl cover, and engage the fingers of the float lever with the neck of the float needle, then slip the pivot screw through the pivot hole in the float lever and insert the screw and lever into the bowl cover, on 1968 and earlier models.

Checking the float level, 1968 and earlier Sprint models

3. Check the float level on 1968 and earlier models in the following manner:

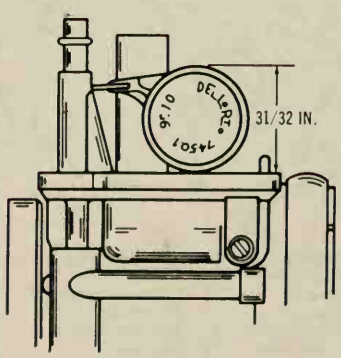
a. Invert the bowl cover and lay a straightedge across the cover's face.

b. Measure the distance from the straightedge to the highest point on the float lever.

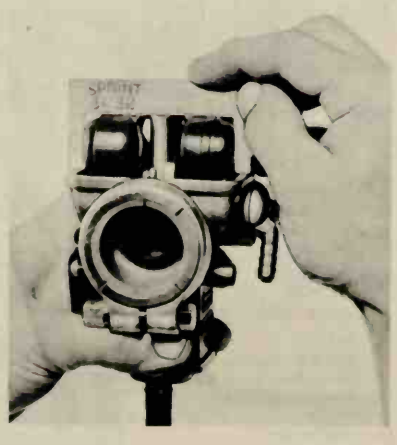


c. If the distance is not within $^{13}/_{64}$–$^{15}/_{64}$ in., the lever can be bent to compensate for the difference if care is taken to bend it evenly. If repeated attempts to get within the specified limits fail, either the lever or the needle is faulty and must be replaced.

4. Check the float level on 1969 and later models in the following manner:



a. Measure the distance from the top of both of the floats to the gasket surface when the inlet valve is seated. The distance should be $^{31}/_{32}$ in. and is best measured with Carburetor Float Gauge (H-D part no. 94751-69) although substitute gauges may easily be made from cardboard or balsa.



b. If the distance is not within specifications, place the float on a flat surface

and bend the tang up or down as necessary.

c. Check to see that both floats are at an even height by seeing whether both are parallel with the pin support when resting on a flat surface.

5. Install the float pin lockring, then engage the float lever fingers with the neck of the float and mount the float in the bowl, taking care to make sure the float shaft sits in the hole provided for it in the bottom of the bowl.

6. Assemble the throttle assembly on 1968 and earlier models in the following manner:

a. Mount the choke rod hairpin spring, friction spring, throttle cable adjusting nut, adjusting screw, and the cap nut on the mixing chamber cap and choke assembly.

b. Slip the needle into place in the throttle slide, place the needle retainer clip on the desired groove. Run the throttle cable through the rubber boot, adjusting screw, and throttle slide spring.

c. Push down on the choke slide, mount the throttle slide assembly on the cable, compress the slide spring by hand, and mount the throttle slide onto the cable.

7. Assemble the throttle assembly on 1969 and later models in the following manner:

a. Slip the needle into the throttle slide, and engage the needle retainer clip in the desired groove of the needle. The middle groove is the one used for normal operation.

b. Run the throttle cable through the rubber boot, adjusting screw, and throttle slide spring, then compress the spring by hand and insert the cable into the throttle slide.

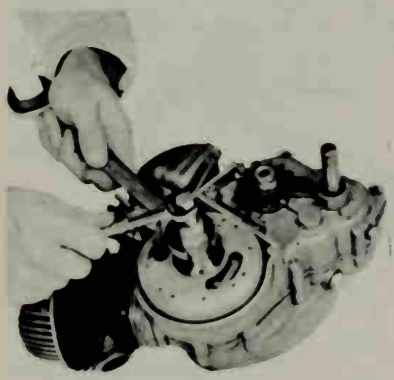
8. Mount the intake manifold on the cylinder, then mount the carburetor on the manifold. On 1968 and earlier models, make sure the float bowl is absolutely level to prevent the float from hanging up.

9. Open the throttle at the handgrip and insert the throttle slide assembly in the carburetor body. Make sure the slide is free and operating smoothly before securing the piston cap.

10. Mount the fuel line and air cleaner assembly, then adjust the carburetor as described in the "Tune-Up" section.

ELECTRICAL SYSTEM

MAGNETO-GENERATOR



M-Models, SR-100, SX/TX 125, X-90, Z-90

DISASSEMBLY

1. Remove the left crankcase side cover as described in the "Starter" section.

2. Remove the rotor shaft nut and washer, then pull the rotor free with Magneto Rotor Puller (H-D part no. 97344-65P or 97302-70M for the MSR models) or a suitable substitute.

3. Remove the coil screws and washers, disconnect the coil leads at their terminals, and remove the coils.

Removing the rotor.

4. Remove the condenser screw and washer, then remove the condenser.

5. Remove the retaining clip and washers, the contact breaker assembly, the stator plate screws and washers, and the stator plate.

INSPECTION

1. Clean all parts other than the coils in a suitable grease-dissolving solvent and blow them dry. The coils may be cleaned with a clean cloth dipped in clean, white gasoline.

2. Inspect all parts for a worn or damaged condition and replace them as necessary. This is a good time to perform a tune-up so you may want to replace the points and condenser. Consult the "Tune-Up" chapter for additional information.

ASSEMBLY

1. Assembly is in the reverse order of disassembly.

2. Check the moving parts for a smooth, free operation.

GENERATOR (MODEL 165)

DISASSEMBLY

1. Remove the generator cover.

2. Remove the brush spring clips, springs, insulators, and the frame mounting screws, and pull the frame clear of the armature.

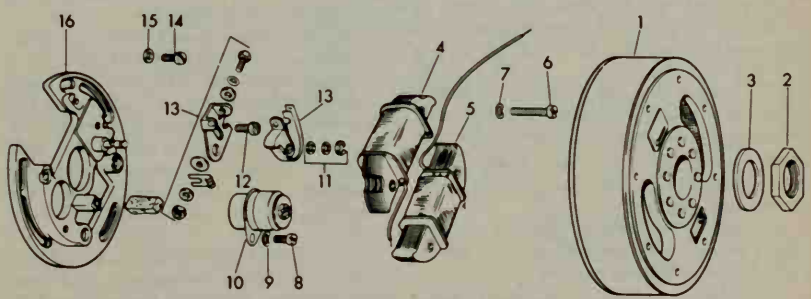
3. Remove the armature mounting screws and lockwashers, and remove the contact breaker cam by tapping gently on its sides with a soft mallet.

4. Remove the armature from the flywheel shaft using Generator Armature Puller (H-D part no. 95900-48) or a suitable substitute. If you don't have the correct tool, consult your dealer for assistance as the armature is easily damaged. Remove the sprocket shaft key from the flywheel shaft.

5. Disconnect the red and green wires in the cable from the fiber terminal block.

6. Disconnect the brush leads and remove the brushes, then disconnect the black wire at the contact point terminal.

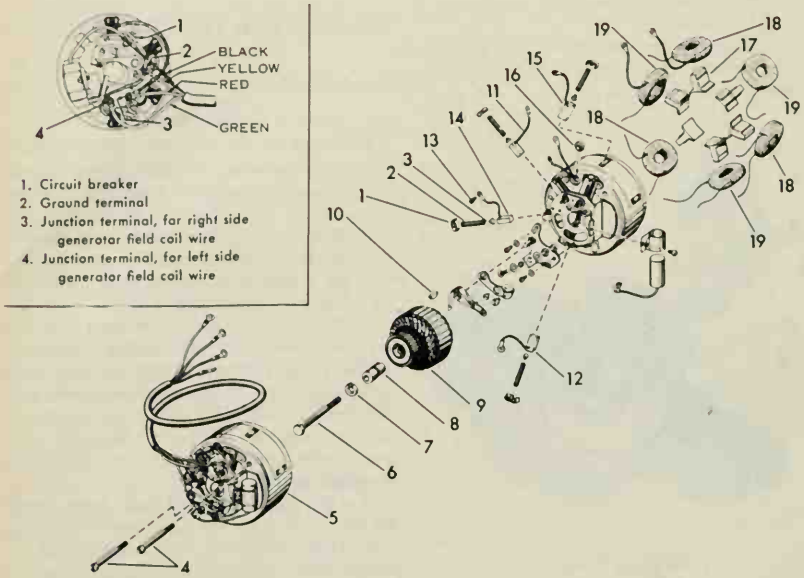
7. Remove the contact breaker and condenser if so desired. This is an excellent time to consider replacing these parts.



8. Inspect the pole shoes and field coils for a worn or damaged condition and remove them only if replacement is necessary. The shoes may be removed by sharply striking the portion which extends through the generator frame with a hammer. The shoes may be reused if there is enough of the peening material left after they have been removed.

INSPECTION

1. Clean all parts other than the armature, field coils, and brushes in a suitable grease-dissolving solvent and blow them dry. Clean the remaining components by wiping them with a clean cloth dipped in clean, white gasoline and then blow them dry.



2. Inspect the insulators, armature windings, field coil wrappings, and the surfaces of the pole shoes nearest the armature for a worn or damaged condition and replace them as necessary.

3. Inspect the brushes for a worn or damaged condition and compare them

with new brushes, if possible, to determine their wear. Replace them if necessary.

4. Inspect the brush holder plate for a warped, burned, loose, or otherwise damaged condition and replace them if necessary in the following manner:

a. Remove the heads by chiseling off the plate rivet heads and drifting the rivets free.

b. Remove the brush holder plate from the generator frame.

c. Drill four holes in the new plate using a no. 20 bit, then tap four corresponding holes into the frame with an $^{8}/_{32}$ in. tap.

d. Mount and secure the new plate to the frame with four screws and lockwashers (H-D parts no. 2626 and 7115) or suitable substitutes.

e. Take care not to damage the pole shoes and not to allow the screws to contact the shoes. If necessary, use additional lockwashers to keep the screws away from the shoes.

5. Inspect the cam fiber follower for a worn or damaged condition and replace it if necessary by knocking out the old part and riveting in a new one. Always keep the felt portion clean and lightly oiled with clean engine oil.

6. Inspect the coils for a worn or damaged condition and replace them as necessary in the following manner:

a. When installing the field coils, there must be a north ("N") coil to the left of the coil lead hole in the generator frame when the frame is held so the engine side is up and the coil lead hole is to the near side of the frame. Coils are mounted in opposite pairs of "N" and "S." and the coils adjacent to one another must also be opposites. (Consult the accompanying illustration for the proper positioning.) North coils may be identified by the white swatch of paint. South coils may be identified by their red marking.

b. Hold a south coil with the concave side up and the leads pointing away. Slip a yellow insulator over the left-side lead then solder the wire tip of the right-side lead to the connector of the left lead.

c. Perform the above operation on a north coil in the same manner except that the insulator and connector are on the right-side lead.

d. Place the south coil to the right of the generator frame coil lead hole.

e. Place a north coil, without an insulator or connector, with a shoe in the frame shoe slot directly to the right of the south coil of step "d."

f. Continue to install coils in an alternating order (the next one will be a south coil) so the last coil—the north coil prepared in step "c"—sits to the left of the generator frame coil lead hole.

g. Place insulation under the coils where the frame mounting screws pass so they don't short out against the frame; use the mounting screws as guides.

7. Secure a length of 2¼ in. outside diameter (OD) pipe horizontally in a vise, then slip the generator frame, complete with coils and shoes, over the pipe as far as is necessary to completely support the frame shoes.

8. Tap the frame down around the shoes with a ¼ in. chisel ground to a dull edge until it bottoms on the shoe shoulders. After each shoe is seated, stake the shoe corners over the generator frame with the chisel, then peen the entire shoe surface of each shoe with a ball peen hammer. Use only as much force as is necessary, and use a light hammer to avoid using excessive force.

9. Inspect the fit of the armature in the frame. If the clearance is less than 0.014 in. (0.007 in. per side) check to see that all of the shoes are well seated. If this was not the problem, the shoes will have to be carefully bored until the clearance is correct.

10. Check each coil for proper current draw and ground as described in the "Component Testing and Repair" section of this section before twisting the coil ends together, then connect the coils in one of the following manners:

a. Twist the adjacent leads together, clip them off at a point ½ in. beyond the edge of the generator frame, and fuse the wires together with a blow torch. (This is the preferred method.)

b. Scrape the coil leads until the varnish is removed, twist the adjacent leads together, and solder the connections.

11. Bend the coil leads back between the coils taking care to keep them from touching the generator frame. Install a rubber grommet over the leads and press them all into the frame hole.

12. Slip the coil leads onto their respective terminal posts mounted on the insulated terminal strip, taking care not to cross any of the leads.

13. Perform the final field coil polarity test in the following manner:

a. Connect wires from the positive terminal of a 6 V battery to the south coil post, and from the negative terminal to the north coil post.

b. Hold a compass outside the generator frame near the pole shoe of the coil to be tested and observe the reaction of the compass. The south needle of the compass will swing toward the pole shoe if the coil is a south coil.

ASSEMBLY

1. Assembly is basically the reverse order of disassembly.

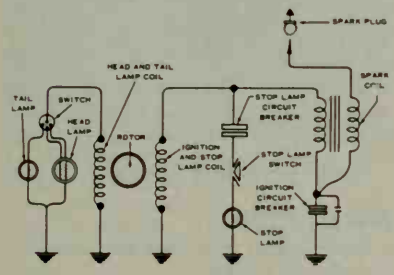
2. Secure the sprocket shaft key and install the armature.

3. Gently tap the contact breaker cam until it begins to seat. then secure it with the lockwasher and armature mounting screw.

4. Mount a dial indicator to the crankcase and check the armature run-out. If the run-out exceeds 0.002 in., the brushes will act erratically at high speeds, causing excessive heat and the damage that is associated with it. The run-out may be reduced by drifting the armature with a small hammer and a suitable brass drift, then recheck the run-out.

5. Check the breaker cam run-out at the portion of the cam nearest the armature (the concentric portion). If the run-out exceeds 0.002 in., it may be reduced by drifting it as you did the armature. Recheck the run-out after drifting the cam.

6. Place a small daub of grease on the cam, and lightly oil the felt cam follower



with a small drop of clean engine oil, then assemble the generator frame.

7. Install the brush spring insulators, springs, and spring clips, reconnect the wires as depicted on the wiring diagrams, time the engine as described in "Tune-Up," and install the generator and sprocket cover.

MAGNETO-GENERATOR (B MODELS)

DISASSEMBLY (ALL MODELS OTHER THAN THE BTF)

1. Remove the right side cover.
2. Carefully pry off the outer and inner cams with a small screwdriver, then remove the cam keys.
3. Disconnect the coil leads from the terminals, pry the large ends of the coil core clamps from the cores, and remove the headlight and ignition coils.
4. Remove the flange mounting screws, lockwashers, flatwashers, and the flange.
5. Pull the rotor using All Purpose Claw Puller (H-D part no. 95635-46) or a suitable substitute. If necessary, grind down the bottoms of the claws to make it fit properly. Remove the rotor key after the rotor is out.
6. Consult the "Tune-Up" section for additional information concerning removing and replacing the breaker point assemblies.

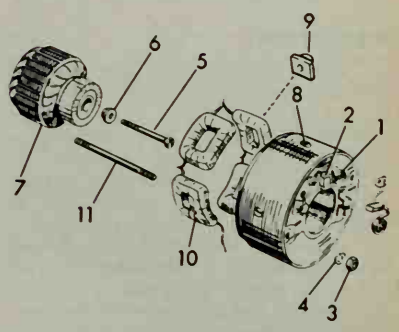
DISASSEMBLY (BTF MODELS)

1. Remove the right side cover.
2. Pry off the cam with a small screwdriver and remove the key.
3. Disconnect the coil leads from the terminals, then pry the large end of the coil core clamps from the cores and remove the flange.
4. Remove the rotor and key as described in the above section.

INSPECTION

1. Clean all parts, other than the coils, in a suitable grease-dissolving solvent and blow them dry. The coils may be cleaned with a clean cloth dipped in clean, white gasoline.
2. Inspect all components for a worn or damaged condition which may impair their performance, and replace them as necessary.
3. Inspect the connection of all wires, and their terminals, for a secure fit.

Magneto-Generator circuit for the Ranger (BTF) model.



ASSEMBLY (BOTH MODELS)

1. Assembly is basically the reverse order of disassembly.
2. Pull the rotor onto the shaft, taking care to avoid jarring it as this could cause it to lose its magnetic properties, by using the cams as drive collars and by turning the shaft nut onto the shaft until the rotor seats itself.
3. Press the coil core clamps into position by applying pressure to the curved portion. Never hammer or tap them into place.
4. Apply a daub of grease to the cam and a small drop of clean engine oil to the fiber cam follower. Reconnect the wires by consulting the wiring diagrams and time the engine as described in the "Tune-Up" section.

2. Remove the brush springs from the brushes, then remove the brushes.
3. Disconnect the wires at the "D+" and "DF" terminals, remove the generator mounting nuts and lockwashers, then pull the generator from the frame studs.
4. Remove the tachometer drive unit (if applicable), the armature mounting screw, and the screw spacer.
5. Using Generator Armature Puller (H-D part no. 97296-61P), or a suitable substitute, pull the armature from the shaft. If you don't have access to this tool or one very much like it, you should consult your dealer for assistance since the armature is easily damaged. The tool has both right- and left-hand threads to suit either type of armature.
6. Inspect the pole shoes and field coils for a worn or damaged condition, and re-

move them if necessary by removing the pole shoe screws which will allow the shoes and coils to come free.

INSPECTION

1. Clean all parts, other than the field coils and brushes, in a suitable grease-removing solvent and blow them dry. The coils and brushes may be cleaned with a clean cloth dipped in clean gasoline.

2. Inspect all components for a worn or damaged condition and replace them as necessary, paying particular attention to the insulators, armature windings, field coil wrappings, and the surfaces of the pole shoes nearest the armature. If possible, compare the brushes with new ones, and replace them if it appears that they may interfere with the normal operation of the generator.

NOTE: *On models after serial no. 3672, the armature and tapered shaft have been altered. Make sure to use the correct replacement parts if replacement is necessary.*

3. Replace the field coils in the order depicted in the illustration. The lead on each end coil is marked with a colored insulating sleeve. The red sleeve is connected to the generator "D+" terminal and the yellow lead goes to the "DF" terminal. Use the Generator Pole Shoe Arbor (H-D part no. 97302-61), or a suitable substitute, to force the coils into position in the frame.

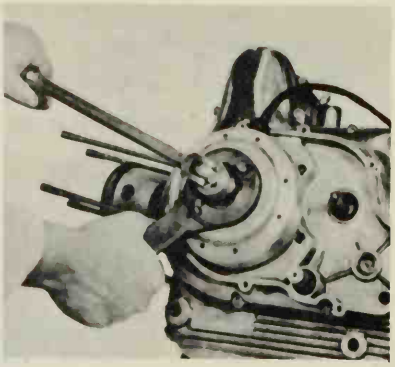
4. Check the twisted connections between the adjacent coils for a positive connection, scrape the leads free of varnish, solder the twisted connections, clip ½ in. off each connection beyond the generator frame, and bend the leads back between the coils, taking care not to touch them to the generator frame.

5. Check the clearance between the armature and the shoes for clearance. If the clearance is less than 0.014 in. (0.007 in. per side) and the shoes have been properly seated, the shoes will have to be bored to fit.

ASSEMBLY

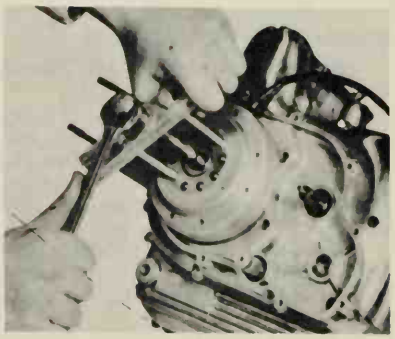
1. Assembly is basically the reverse order of disassembly.

2. Secure the armature with the armature mounting screw spacer and screw, then check the armature run-out for run-out in excess of 0.002 in. Consult the Model 165 Generator section for additional information.



3. Slip the generator frame onto the frame studs and secure it with the lockwashers and nuts.

4. Install the brushes and springs, reconnect the wiring as depicted in the wiring diagrams, and mount and secure the left crankcase cover.



ALTERNATOR (1973 AND LATER) SPRINT MODELS

REMOVAL

1. Remove the left crankcase cover. Remove the alternator rotor nut (left-hand thread) and washer from the end of the crankshaft. The crankshaft will have to be held while the rotor nut is being removed. This can be accomplished with the use of a special tool (H-D part no. 97306-73P) or, if the engine is in the frame, place the transmission in gear and apply the rear brake. An impact driver will make removal easier.

Removing the alternator rotor nut

Removing the alternator rotor

2. To remove the rotor a special puller is needed. The puller can be constructed using the body of the gear puller (H-D part no. 97292-61P) and two bolts (H-D part no. 52081-63P). Slip the two bolts through the puller and thread them into the alternator rotor. Use the puller to remove the rotor. Remove the key from the crankshaft.

3. Remove the four mounting screws securing the stator to the left crankcase.

INSTALLATION

1. Mount the stator to the left crankcase.

2. Install the key into the slot in the crankshaft.

3. Mount the rotor on the crankshaft. Draw the rotor down on the crankshaft with the rotor nut and washer.

CAUTION: *Never strike the rotor to seat it as this may decrease its magnetic properties.*

4. Check that the rotor does not rub on the stator as it rotates.

ALTERNATOR SX/SS 175/250

REMOVAL

1. Remove the left crankcase cover. Remove the alternator rotor nut and washer from the end of the crankshaft. The crankshaft will have to be held while the rotor nut is being removed. This can be accomplished with the use of a special tool (H-D part no. 97352-71MA) or, if the engine is in the frame, place the transmission in gear and apply the rear brake. An impact driver will make removal easier.

2. Remove the rotor from the end of the crankshaft with the special tool (H-D part no. 97302-70M).

3. Remove the pick-up coil mounting screws and remove the pick-up coil. Disconnect the neutral switch lead, and stator wiring.

4. Remove the three mounting screws, and remove the stator from the crankcase.

5. The key in the crankshaft should be inspected in place and replaced if necessary.

Removing the rotor with a special puller

INSTALLATION

1. Installation is the reverse of removal. Note the following;

a. Draw the rotor down on the crankshaft with the rotor nut and washer.

NOTE: *Never strike the rotor to seat it as this may decrease its magnetic properties.*

b. When installation is complete, check that the rotor does not rub the stator when rotated.

c. Reset the ignition timing.

COMPONENT TESTING

Magneto-Generator (All Models)

On 1969 and earlier M models the brake light circuit is tied into the ignition circuit. In normal operation the brake light switch is closed, providing the necessary ground. When the brake is applied, the switch opens and the light filament provides the ground. If the machine stalls out when the brake pedal is operated, the problem is probably in the brake light bulb or wiring. After replacing the bulb or fixing the wir-

ing, recheck the ignition for spark as previously described. If you still haven't located the source of the problem, it's probably in the lower coil of the magneto-generator.

TESTING FOR A GROUNDED COIL

1. Remove the rotor and disconnect both of the leads from the coil in question.
2. Connect a taillight bulb in series with a 6 V battery, then connect one lead of the test circuit to one of the coil leads and ground the other to the generator frame.
3. Wrap the remaining coil lead to insulate it, or place it in such a way that it is not touching the frame.
4. If the test light comes on, the coil is grounded or faulty. Inspect the coil windings for a worn, frayed, or damaged condition and replace as necessary.

TESTING FOR A SHORTED COIL

There is no accurate method of testing for a shorted coil without elaborate test equipment. The best method is to replace the bulbs which are in circuit with the coil in question and the coil, and then compare the intensity with another bulb. Since your dealer probably won't let you return any electrical component you use, what it boils down to is that if you've eliminated all other possibilities, it's time to replace the coil.

TESTING FOR AN OPEN COIL

1. Remove the rotor and coil, and connect both test leads of a taillight bulb in series with a 6 V battery to the two coil leads.
2. If the bulb doesn't light, the coil has an open circuit and must be replaced.

TESTING THE ROTOR

When all other tests fail to reveal the source of the malfunction, the rotor may be considered. If damaged or roughly handled, the rotor may lose some of its magnetic properties. The only test is to compare the strength of the magnets with a new rotor, and replace the rotor if the tests prove it to be low in magnetic energy.

Generator (Model 165)

TESTING THE CHARGING SYSTEM

1. Disconnect the red wire at the voltage regulator "gen" terminal and connect one lead of an ammeter to the red wire and the other lead to the terminal. Turn on the headlight, then start and run the engine until the normal operating temperature is reached. Open the throttle until the engine is running at a speed equivalent to 20–25 miles per hour (mph) road speed. (This may be done by blocking the machine up so the rear wheel spins freely and then running the engine in high gear until the speedometer indicates the appropriate speed.) The ammeter should indicate a charge under these circumstances, but if it doesn't, go on to the next step.
2. If the above procedure fails to produce a charge on the ammeter, disconnect the green wire at the regulator "F" terminal (without disconnecting the test circuit) and ground it on the crankcase while observing the ammeter. If the ammeter records a charge of five or more amps, either the voltage regulator is not properly grounded or it is defective. Check to see that the regulator is properly grounded before going on to the next test.
3. Compare the regulator connections to the wiring diagrams to make sure everything is properly connected. Flash the regulator "gen" and "bat" terminals by momentarily touching a piece of wire to both of them. This will correctly polarize the generator to keep it charging and to keep the relay points from arcing and burning. Run the engine after polarizing the generator and see if the generator charges as in step one. If the generator fails to charge, go on to the next step.
4. Disconnect the test circuit ammeter lead from the "gen" terminal and connect it to the positive (+) battery terminal, then ground the wire from the "F" terminal on the crankcase. Run the machine as described in step one and read the ammeter. If the ammeter doesn't record a charge, the trouble is within the generator.
5. Inspect the brushes and brush springs for a worn or damaged condition and replace them if necessary. At least clean them with trichloroethylene or a suitable solvent such as clean white gasoline. Polish the commutator with no. 00 sandpaper and blow the assembly clear. Recheck the output as in the above step and proceed to disassemble the generator as described earlier in this chapter if the generator still is not working properly, and go on to the next section.

TESTING THE FIELD COILS

Perform the following tests with the generator frame in place after disconnecting the red and green wires from the regulator terminals, and removing the positive brushes which are connected to the same terminal as the red wire. If the ammeter is connected to a short circuit, it will overload and be damaged. If the needle starts to go off the range, the contact should immediately be broken. For this reason it is advisable to momentarily touch the ammeter leads to the terminals or leads to check for a short before securing them.

1. Connect a fully charged 6 V battery and an ammeter in series with the red and green leads and consult the ammeter. The correct reading should be 2 amps. If it is not, go on to the next step.
2. If the above test results in a reading which is higher or lower than the specified amount, or if the test reveals a short circuit, disconnect the red and green wires and the field coil leads from the terminals. Connect the test circuit to the field coils and repeat the test described in step one before going on to the next step.
3. If the reading in step two is correct, inspect the condition of the red and green wires for wear or damage and replace them as necessary. If the wires are all right but a short was discovered in the first step, check to see that the frame terminals are insulated from each other and from the generator frame as well. Inspect the positive brush holders also to make sure they are fully insulated from the generator frame.
4. If tests of the field coils, independent of all terminals and leads, fail to provide the correct reading, the generator frame must be thoroughly cleaned before proceeding to the next step.
5. If an open (no reading) or low reading is arrived at after cleaning the frame, inspect all the connections of the coil leads and of the twisted connections between the coils before proceeding to the next step.
6. If everything checked out in the previous step, cut off the fused portion between the coils and separate them for individual testing. Each coil may be tested with a fully charged 2 V battery instead of the 6 V used in the first step. A correct reading for individual coils is about 3.3 amps.
7. An alternate method to step six is to replace the 6 V battery as the power source for the circuit tester, wire a taillight bulb into the test circuit, and then connect one test lead to the generator frame, and use the other to individually test each coil by touching one coil lead while observing the test light and ammeter responses. If the light lights, the coil is grounded. If there is no reading, the coil is open. If the reading is high the coil is shorted. In any of these cases the coil must be replaced as described in the "Generator (Model 165)" section.

TESTING THE ARMATURE

Remove the armature from the generator as described in the "Generator (Model 165)" section. Connect a taillight in series with a 6 V battery, then touch one lead to the commutator surface and the other to the armature core. If the light comes on, replace the armature.

REPAIRING THE COMMUTATOR

If a lathe is available, the commutator may be turned down enough to remove the rough surface. Armature Commutator Turning Arbor (H-D part no. 96170-50) may be used since it easily mounts in the lathe chuck, but any suitable substitute may be used. Once the commutator is turned down (never remove more metal than necessary), it may be finished with some no. 00 sandpaper. Emery cloth should not be used since the particles will embed themselves in the mica and cause an electrical malfunction.

The mica between the commutator segments will have to be cut to a depth of 0.025 in. if the commutator has been turned or worn down. The cutting may be done with an under-cutting tool or with a piece of hacksaw blade that has been thinned to the appropriate size. Try to make the surface of the mica as flat and as even as possible. Smooth the commutator with no. 00 sandpaper after everything is done, and recheck the armature as described in the above section before installing it.

If all of the above sounds too complicated or if no lathe is available, the commutator may be cleaned by hand, using no. 00 sandpaper. Always make sure that the armature is perfectly clean before reinstalling it.

Generator (Sprint Models)

TESTING THE CHARGING SYSTEM

1. Compare the regulator wiring to the

wiring diagram located at the end of this chapter to make sure it is correct.

2. Disconnect the two white wires at the voltage regulator no. 61 terminal, then connect the negative lead of an ammeter (0–15 amp DC type) to the no. 61 terminal and the positive lead to both of the white leads. Turn on the headlight, then start and run the engine until normal operating temperature is reached. With the engine running at a speed equivalent to 20–25 mph, the ammeter should register some charge. The bike may be blocked up and run in high gear to approximate the moving speed. Go on to the next step if the ammeter fails to register a charge.

3. Remove the red wire from regulator "DF" terminal if the ammeter didn't register, and briefly touch the wire to the crankcase without disconnecting the test circuit. If the ammeter indicates a charge of five or more amps, the generator is healthy and the problem lies in the voltage regulator or any of the charging system wiring. Inspect the wiring for bad connections, breaks, or a poor grounding of the battery negative terminal or regulator base.

4. Polarize the generator with the battery by momentarily connecting a jumper wire between the battery positive terminal and the regulator no. 61 terminal or the generator "D+" insulated brush (depending on which component or wiring has been worked on). Do this before running the engine as otherwise the relay points may be burned. Repeat step one and go on to step five if the generator does not charge.

5. Remove the wire from the regulator "DF" terminal (after turning off the bike) and place it so it can't make contact with the terminal. Disconnect the negative ammeter lead from the no. 61 terminal and start and run the engine as described in step one. While the engine is running, connect the negative lead of the ammeter to the positive terminal of the battery, and connect the red regulator wire to the regulator base or any other ground on the motorcycle. Observe the ammeter and keep these connections in place only as long as is necessary to get a reading or the battery will discharge through the generator since these connections completely bypass the regulator. If the ammeter shows either no charge or one which is erratic and very low, the trouble is in the generator.

6. Inspect the brushes for a worn or damaged condition and replace them as necessary. At least clean them with trichloroethylene or a suitable solvent such as clean white gasoline. Polish the commutator with no. 00 sandpaper and blow the assembly clear. Recheck the output as in the above step and proceed to disassemble the generator as described earlier in this chapter if the generator is still not working properly, and go onto the next section.

TESTING THE VOLTAGE REGULATOR

Perform the following tests to make sure the regulator is operating correctly. All tests should be made with the engine at its normal operating temperature and all the lights and accessories turned off. If the regulator proves to be defective in these or in the previous "Generating System" tests, it must be replaced.

1. Connect the voltmeter positive lead to the regulator's "B+" terminal, and ground the negative lead.

2. Run the engine at about 3500 revolutions per minute (rpm) or about 30 mph road speed, with the regulator cover in place, and read the voltmeter.

3. A properly operating regulator will read 7.0–7.5 V.

4. An overactive regulator will read above 7.5 V and will damage the battery by overcharging it.

5. A tired regulator will read below 7.0 V and will constantly allow the battery to discharge.

TESTING THE FIELD COILS

Perform the following tests with the generator frame in place after disconnecting the red and white wires from the regulator terminals, and removing the positive brush (the brush connected to the same terminal as the white wire) from the generator frame. The testing procedures are the same as in the "Generator (Model 165)" section earlier in this chapter, except that the complete field circuit should draw 4.4–4.8 amps for 1961–62 C models at 6 V and 2.0–2.2 amps at the same voltage for 1963–66 C models and 1962 and later SS models. In step six, the reading should be the same as those given here instead of being different as they are for the Model 165.

TESTING THE ARMATURE

Consult the "Generator (Model 165)" section.

REPAIRING THE COMMUTATOR

Consult the "Generator (Model 165)" section.

Alternator (Sprint Models)

TESTING FOR A GROUNDED COIL

Connect a test light between the black coil lead and ground. If the bulb lights, one or both of the coils are grounded. In this case, disconnect the black wire connecting the coils together. Connect the test light between each coil and ground. If the bulb lights the coil is grounded.

TESTING FOR AN OPEN CIRCUIT

Connect the leads of a test light to the two coil leads (black and green). If the bulb doesn't light, the coil has an open circuit and must be replaced.

TESTING FOR A SHORTED COIL

Connect an ohmmeter to the brown and green coil leads. The resistance should be about 0.8 ohms (both coils). Then connect the ohmmeter between the brown and black leads and the green and black leads, in either case the resistance should be about 0.4 ohms (one coil). If the resistance is less than specifications, it is shorted, and should be replaced.

TESTING THE ROTOR

When all other tests fail to reveal the source of the malfunction, the rotor may be considered. If damaged or roughly handled, the rotor may lose some of its magnetic properties. The only test is to compare the strength of the magnets with a new rotor, and replace the rotor if the tests prove it to be low in magnetic energy.

STARTER MOTOR

Removal

1. Remove the left crankcase cover and the kick-starter assembly.

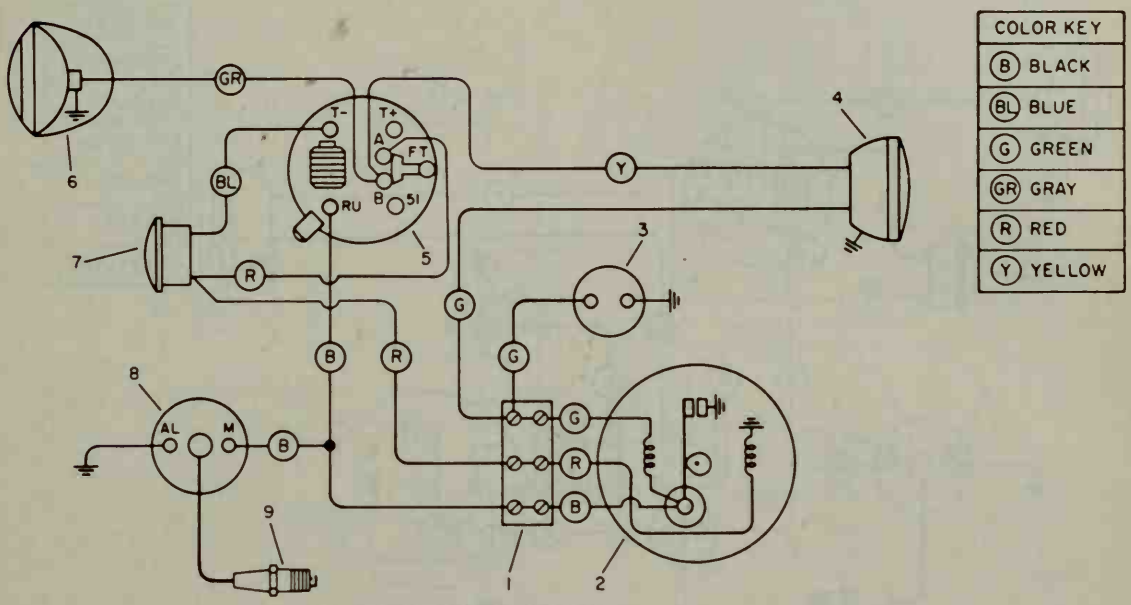
2. Remove the circlip from the starter motor shaft.

3. Use a small gear puller to remove the starter motor sprocket. Remove the chain and the large crankshaft sprocket at the same time as the starter motor sprocket. Remove the flat washer and any thrust washers located behind the starter motor sprocket. Remove the spacer from the chankshaft.

4. Use a gear puller or the special tool (H-D part no. 97309-73P) to pull the starter clutch from the crankshaft. Remove the key and the starter clutch spacer from the crankshaft.

5. Remove the two mounting bolts securing the starter motor to the crankcase and remove the starter motor. Avoid tapping on the starter motor shaft, if necessary, tap the motor on the case to remove it.

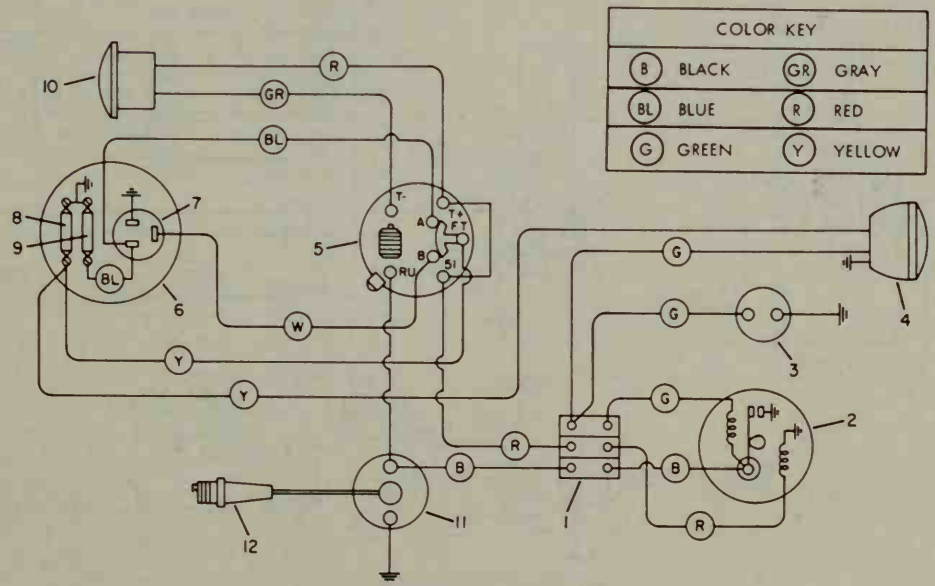
Installation



1. Inspect the O-ring on the starter motor case and replace it if damaged in any way. Position the starter motor on the crankcase and install the two mounting bolts and lockwashers.

2. Install the starter clutch spacer and key on the crankshaft. The flat side of the key faces away from the engine.

3. Press the starter clutch on the crankshaft using the special tool (H-D part no. 97308-73P) or a suitable substitute. Install the crankshaft sprocket spacer on the crankshaft with the recess facing the engine.



4. Install any thrust washers that were removed, and the flat washer on the end of the starter motor shaft. Install the crankshaft sprocket, starter motor sprocket, and starter chain at the same time. Secure the starter motor sprocket with the circlip.

CHASSIS

DRIVE

The large trail sprocket used on 1970 and later MLS and TX Models is put into operation in the following manner:

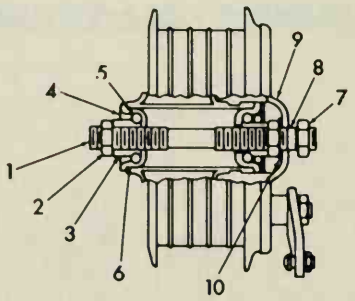
1. Disconnect the master link and wire the ends of the chain to the frame so the chain does not come off the front sprocket.
2. Remove the four bolts which hold the sprocket dowel pins in place against the standard sprocket and disconnect the drive chain.
3. Rotate the sprocket so the dowel pins seat in their respective holes in the standard sprocket, and secure the four bolts.
4. Add a short length of chain to the standard chain and secure the master link.
5. Adjust the chain and rear brake as described in the "Maintenance" section.

WHEELS

M, MS, and 1973 Z-90

FRONT WHEEL

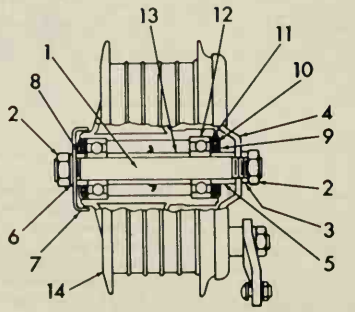
Removal and Installation



1. Block up the motorcycle so there is enough room to remove the front wheel. The machine must be well balanced.
2. Remove the axle nuts and washers from both sides of the axle, and let the wheel slip down and away from the forks.
3. Remove the speedometer drive unit from the axle and also remove the brake securing nut, spacer, and washer (if applicable) to free the front brake.
4. Installation is the reverse order of removal, taking care to have the side-plate slot straddle the fork side anchor boss.
5. Install the speedometer drive unit, then mount the wheel in the fork and secure it with the washers and nuts, taking care to seat the axle correctly in the fork side slots.
6. Adjust the front brake and check the axle nuts for tightness.

WHEEL BEARINGS

Removal and Installation



CONE TYPE BEARINGS

1. Remove the front wheel as described in the above section, loosen the locknut and bearing cone, and slip the axle from the hub.
2. Remove both sets of bearings, inspect the bearing cups for a worn, scored, or damaged condition, and, if they are in need of replacement, tap them out.
3. Inspect the dust covers for a worn or damaged condition and remove them only if in need of replacement.
4. Carefully tap the bearing cups into place in the hub, pack them with fresh grease, install the bearings (11 to a side), and install the dust cover.
5. Slip the axle into place, and replace the bearing cones and locknuts.

13. Spacer
14. Hub, front wheel

6. Adjust the bearings as described in "Maintenance."

RETAINED BALL TYPE BARINGS

1. Remove the locknut, spacer, brake side-plate, and inner spacer to free the axle, and remove the axle with the left-side locknut, dust shield, and spacer.
2. Carefully pry the felt seal retainers from the hub with a suitable screwdriver, and remove the felts and washers.
3. Tap the bearings out from their respective opposite sides, and remove the bearing spacer.
4. Install the spacer in the hub, then press the bearings into the hub until the outer races bottom on the hub shoulders.
5. Assemble the seal washers, felts, and the felt seal retainers to the hub. When tapping in the retainers, take care to do so evenly to avoid damaging them.
6. Continue the assembly procedure in the reverse order of disassembly.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.
2. Inspect all parts for a worn or damaged condition, paying particular attention to the cones, cups, and bearings. If any of the bearings are in need of replacement or if any are lost, they must be replaced as a complete set. Always repack the bearings in fresh grease before reinstallation in the hubs.
3. Inspect the brake shell and shoes for a worn, damaged, or glazed condition, and repair or replace them as directed in the "Brakes" section.

REAR WHEEL

Removal and Installation

1. Block up the rear wheel of the motorcycle so there is enough room to allow removal of the rear wheel. Make sure the machine is well balanced.
2. Disconnect the drive chain master link and wire the chain to the frame to keep it from coming off the front sprocket.
3. Remove the brake rod adjusting nut and disconnect the brake rod from the brake actuating lever.
4. Loosen the axle nuts and slip the wheel out the back of the frame along with the adjusting mechanism.
5. Install the wheel in the reverse order of removal, making sure that the wheel is aligned in the fork, and that the chain and rear brake are adjusted.

WHEEL BEARINGS

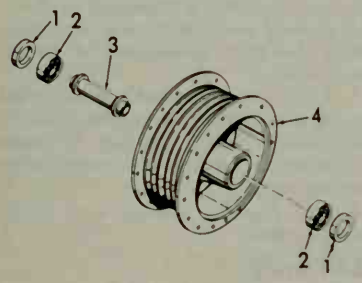
1. Consult the "Wheel Bearings" section under "Front Wheel" for removal, installation, and inspection procedures.

ML, MLS, MSR, SR, SS/TX 125, and 1974 and Later Z-90

FRONT WHEEL

Removal and Installation

1. Block up the motorcycle so there is enough room to remove the front wheel, making sure the machine is well balanced.
2. Remove the axle nut and washer, loosen the axle pinch bolt located on the fork leg, and tap on the right side of the axle with a soft mallet to get the axle started out. Pull the axle the rest of the way out while holding the wheel steady with one hand.
3. Remove the speedometer drive unit from the left side and slip the wheel down and out of the forks.
4. Remove the brake side-plate and the wheel hub spacers.
5. Installation is basically the reverse order of removal.
6. Position the brake side-plate so the side-plate slot engages the fork leg anchor boss.
7. Slip the stepped spacer on the speedometer drive unit side and the thinner spacer on the brake side. Position the brake side-plate and the speedometer drive unit on the hub and slip a thin washer between the drive unit and the fork leg.
8. Juggle the wheel assembly into place, and insert the axle from the left side. Secure the axle washer and nut on the right side, remove the bike from the blocks, and pump the forks up and down to center the fork legs.
9. Secure the axle pinch bolt and adjust the brake as described in "Maintenance."



REAR WHEEL

Removal and Installation

1. Block up the motorcycle so there is enough room to remove the wheel, making sure the machine is well balanced.
2. Remove the drive chain master link and wire the chain ends to the frame to keep the chain from coming off the front sprocket.
3. Remove the brake adjusting nut and remove the cable from the actuating lever.
4. Remove the axle nut, washer, adjusting cam, axle, and wheel. The axle may be tapped out with a soft mallet.
5. Installation is in the reverse order of removal.
6. Slip the shorter spacer into place between the brake side-plate and the right-side wheel bearing, and the longer spacer between the axle clip and the left-side wheel bearing. The brake side-plate slot must engage the fork anchor stud.
7. Secure the axle washer and nut and adjust the chain and brake as described in "Maintenance."

REAR SPROCKET REMOVAL AND INSTALLATION

1. Remove the rear wheel as described in the rear wheel "Removal and Installation" section.
2. Remove the hub bolts, lockwashers, nuts, and outer disc, and pull the sprocket and rubber bushings from the hub.
3. Clean all parts in a suitable solvent and blow them dry, then install the sprocket in the reverse order of removal.
4. Position the rubber bushings in the hub, place the sprocket in place so the dowel pins engage the bushings, position the outer disc, and secure the assembly with the nuts, lockwashers, and bolts.
5. Install the wheel and adjust the chain and brake as described in "Maintenance."

S and B Models

FRONT WHEEL

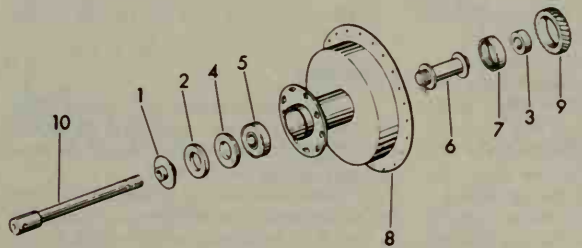
Removal and Installation

1. Block up the motorcycle so there is enough room to remove the front wheel, making sure the machine is well balanced.
2. Remove the cotter pin, washer, and clevis pin from the front brake lever, then remove the lower locknut and withdraw the cable.
3. Remove the speedometer drive grease fitting and pull the housing free of its socket to remove the cable. Do not lose the speedometer drive gear which is a slip fit on the speedometer cable and may come out with the cable.
4. Remove the axle nut and lockwasher, loosen the pinch bolt on the left side, tap out the axle with a soft mallet, and remove the wheel.
5. Repack the wheel bearings with fresh grease before replacing the wheel which is done in the reverse order of removal.
6. Make sure the brake side-plate torque pin engages the fork anchor stud.
7. Lubricate the speedometer drive unit and adjust the front brake as described in "Maintenance."

WHEEL BEARINGS

Removal and Installation

1. Remove the front wheel as described in the above section.
2. Remove the bearing grease retainer, retainer felt seal, bearing inner race, and unscrew and remove the bearing locknut.
3. Carefully drift out the bearing with a suitable drift from the opposite side of the hub, if necessary, and remove the bearing spacer.
4. Invert the hub and drift out the needle bearing from the opposite side of the hub using a suitable drift.
5. Pack the ball bearing in fresh grease and carefully press it into place in the hub until seated against the hub shoulder.
6. Install the bearing locknut, slip the bearing spacer into place, and press the needle bearing into place until seated against the remaining hub shoulder. When pressing on the bearing make sure only to press on the printed side.
7. Grease the bearing and insert the inner race, then install the grease retainer felt seal and the retainer.
8. Mount the wheel and adjust the brake as described in the front wheel "Removal and Installation" section.



Inspection

1. Clean all parts in a suitable solvent and blow them dry.
2. Inspect the bearings for a worn, pitted, burned, or damaged condition, excessive side or radial play, or rough motion and replace them as necessary.
3. Inspect the brake shell and shoes for a worn, scored, glazed, or otherwise damaged condition and replace or repair them as described in the "Brakes" section.
4. Inspect the speedometer drive gear for wear or damage, especially to the gear teeth. The Speedometer drive gear can be removed for replacement with Sprocket Shaft Extension Puller (H-D part no. 96015-56) or a suitable substitute, and the Sprocket Shaft Extension Collar. A suitably sized press plug will have to be used, and the plug must allow sufficient clearance so the gear can move over it. Press the gear flush with the face of the hub when replacing it.

REAR WHEEL

Removal and Installation

1. Block up the motorcycle so there is enough room to remove the rear wheel, making sure the machine is well balanced.
2. Disconnect the master link and wire the chain to the frame to prevent it from running off the front sprocket.
3. Loosen the rear wheel adjusting stud nuts on both sides, disconnect the brake rod at the lever, loosen the right-side axle nut until the adjusting studs can be removed from their slots in the sides of the frame, and remove the rear wheel.
4. Remove the axle nuts, lockwashers, adjusting studs, the right side spacer (1963 and later models), and the brake side-plate.
5. Installation is in the reverse order of removal.
6. Repack the wheel bearings before replacing the wheel. To do this, the felt seals will have to be removed.
7. Make sure the brake side-cover slot engages the fork leg anchor stud, and adjust the chain and brake as described in "Maintenance" after the wheel is mounted

WHEEL BEARINGS

Removal and Installation

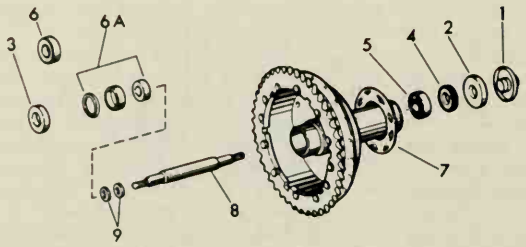
NOTE: *The Model 165 hub is not interchangeable with the hubs used on the B Models.*

1. Remove the rear wheel as described in the above section.
2. Remove the bearing grease retainer and the left and right felt seals, then screw off the bearing locknut.
3. Drift out the left and right ball bearings (only the Model 165 has a right-side bearing), if necessary, from the opposite sides of the hub, and drift out the needle roller bearing, inner race, and washer on Hummer and Super-10 models
4. Pack the left-side bearing with grease and carefully press it into place against the hub shoulder until seated, and secure it with the bearing locknut.
5. Slip two washers onto the sprocket side of the rear axle, and slip the axle into place in the hub.
6. Pack the left bearing or the needle bearing (whichever is applicable) with grease and press it into place in the hub until seated.
7. Mount the felt seals and the felt seal retainer, then install the rear wheel as described in the "Rear Wheel Removal and Installation" section.

Inspection

1. Consult the front wheel "Inspection" section.

REAR SPROCKET REMOVAL AND INSTALLATION

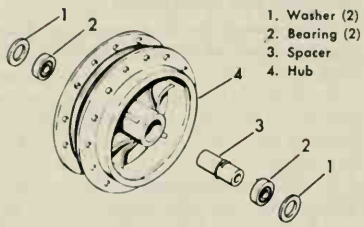


1. Remove the wheel from the bike as described in the "Rear Wheel Removal and Installation" section.
2. Center-punch the rivet heads from the outside sprocket face, then drill them out. Punch the rivets out and install the new sprocket using the bolts which come with the replacement kit. Drilling is not necessary.
3. Install the wheel and adjust the chain and brake as described in the "Rear Wheel Removal and Installation" section.

SS/SX 175/250

FRONT WHEEL

Removal and Installation



1. Support the front wheel off the ground by placing a crate or another suitable object beneath the engine.
2. Remove the fitting from the lower end of the brake cable, and withdraw the cable from the brake plate.
3. Remove the axle nut and the washer behind it. Remove the nut securing the brake anchor to the brake plate.
4. Loosen the fork slider pinch-bolt(s). Note that some models have only one pinch-bolt on the right-side while others have one fitted to either fork leg.
5. Using a plastic mallet, tap the axle lightly on the left-side to free it up. Remove the axle and withdraw the wheel.
6. Installation is the reverse of removal. Be sure that the tab on the speedometer drive is fitted to the hole in the hub.

WHEEL BEARINGS

Removal and Installation

1. Remove the wheel.
2. Remove the speedometer drive, and the brake plate. Note the location of any washers or spacers.
3. Using a thin screwdriver, pry the washers out of either side of the hub.
4. Remove the wheel bearings by reaching through the center of the hub with a long drift and tapping one of the bearings evenly around its circumference until it is removed. Be careful not to turn the bearing sideways in its seat on removal as there is danger of causing damage to the hub.
5. When either bearing is removed, the spacer tube can be removed from the hub. After removing the spacer tube, remove the other bearing in the same manner as the first.
6. Installation is in the reverse order of removal; however, note the following points:
   a. Obtain a good grade of wheel bearing grease (such as Lithium or Moly) to lubricate the wheel bearings.
   b. Pack the wheel bearings until they are completely filled.
   c. Place a small amount of wheel bearing grease to the inside of the hub and drive one of the bearings into its seat. Install the retainer if so equipped. Install the spacer tube and drive the other bearing into its seat. The sealed surface of the bearing must face the outside of the hub.

Inspection

1. Clean the bearings and spacer tube in a suitable solvent, removing all of the old grease. At this point, it would be wise to clean out the hub as well.
2. Check the bearing bosses in the hub for scuffs, cracks, or distortion. If they are in any way damaged, the hub must be replaced.

7. Wheel

3. Check the condition of the spacer tube, and replace it if damaged.
4. Bearing condition is very important. Check the balls themselves for pitting, wear, or rust.
5. Apply a few drops of light oil to the bearing and spin it. The bearing must rotate smoothly and freely. Any roughness or binding in rotation will necessitate a new bearing.
6. Note that the bearings must be replaced in pairs.

REAR WHEEL

Removal and Installation

NOTE: *The following procedure is to remove the wheel only. To remove the brake and sprocket assembly, refer to "Sprocket Assembly" following.*

1. Support the motorcycle so that the rear wheel is off the ground.
2. Remove the axle nut, washer, and chain adjuster from the right-side of the swing arm.
3. Pull the axle out from the left-side. If necessary, tap the right-side of the axle with a plastic mallet to free it up.
4. Remove the spacer from the right-side of the hub.
5. Pull the wheel over to the right-side of the swing arm to free it from the sprocket assembly, then remove it.
6. Install the wheel by reversing the removal procedure.

WHEEL BEARINGS

Removal and Installation (Steel Hub)

1. Remove the wheel as described above.
2. Remove the rubber coupling from the hub or sprocket assembly.
3. Pry the small spacer from the right-side of the hub. Remove the felt dust seals from either side of the hub.
4. Tap the bearings out of the hub from the opposite side of the hub using a long

drift. Tap the bearing evenly around its circumference so that it comes straight out of its seat. After the first bearing is removed, remove the spacer in the center of the hub.

5. Installation is in the reverse order of removal; however, note the following points:

a. Obtain a good grade of wheel bearing grease (such as Lithium or Moly) to lubricate the wheel bearings.

b. Pack the wheel bearings until they are completely filled.

c. Place a small amount of wheel bearing grease to the inside of the hub and drive one of the bearings into its seat. Install the retainer if so equipped. Install the spacer tube and drive the other bearing into its seat. The sealed surface of the bearing must face the outside of the hub.

Removal and Installation (Aluminum Hub)

1. Remove the wheel.
2. Remove the rubber coupling from the hub or sprocket assembly.
3. Remove the plate from the right-side of the hub.
4. Remove the snap-ring from the right-side of the hub and pull the right wheel bearing from the hub. Remove the center spacer from inside the hub.
5. Remove the short spacer from the left-side of the hub, and pry out the seal beneath it. Take care that the seal is not damaged if it must be reused.
6. The left wheel bearing can be removed by tapping it out from the right-side. Do not allow it to become cocked in its seat on removal as the hub may be damaged.
7. Installation is in the reverse order of removal; however, note the following points:

a. Obtain a good grade of wheel bearing grease (such as Lithium or Moly) to lubricate the wheel bearings.

b. Pack the wheel bearings until they are completely filled.

c. Place a small amount of wheel bearing grease to the inside of the hub and drive the right wheel bearing into its seat. Install the snap-ring into the right-side of the hub. Install the center spacer into the hub and drive the left wheel bearing into its seat. The sealed surface of the bearing must face the outside of the hub.

Inspection

For inspection procedures refer to the wheel bearing inspection under "Front Wheel."

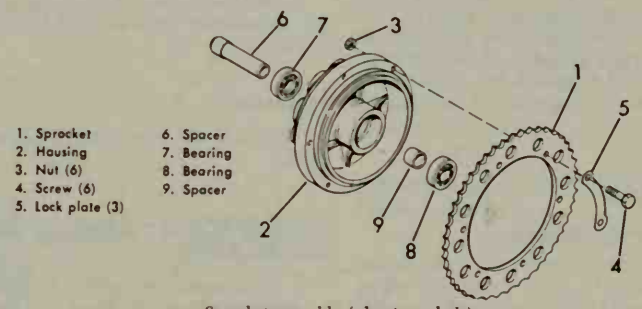
Sprocket Assembly

REMOVAL AND INSTALLATION

1. Support the motorcycle so that the rear wheel is off the ground.
2. Remove the drive chain masterlink spring clip, cover plate, and masterlink. Remove the drive chain from the rear sprocket. The chain need not be removed from the countershaft sprocket.
3. Unscrew the nut from the end of the brake cable. Unscrew the brake adjuster fitting from the brake plate, and remove the cable from the brake plate.
4. Remove the nut securing the brake anchor to the brake plate and disengage the brake anchor. Remove the bolt securing the brake anchor to the frame and remove the brake anchor.
5. Remove the axle nut, washer, and chain adjuster from the right-side of the swing arm. Remove the axle.
6. Remove the wheel and sprocket assembly from the swing arm as a unit. Pry the sprocket from the hub.
7. Installation is in the reverse order of removal.

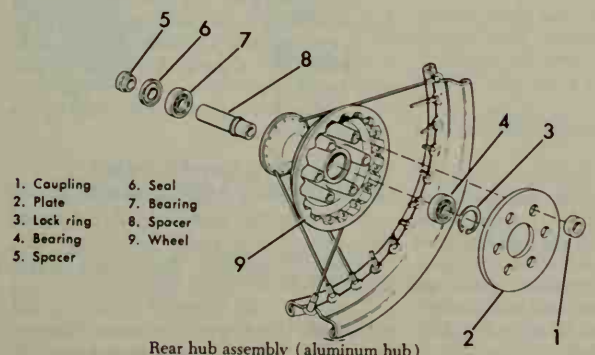
Sprint Models

FRONT WHEEL



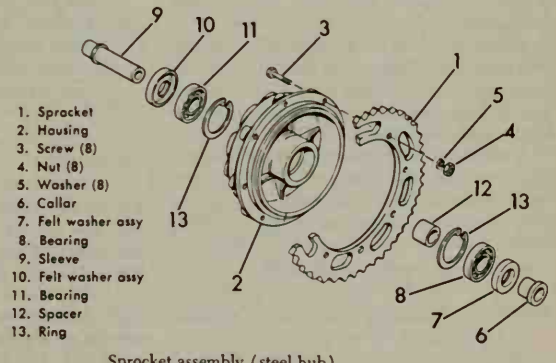
Removal and Installation

1. Block up the front end of the bike so there is enough room to remove the front wheel, making sure the machine is well balanced.
2. Remove the axle nut and washer from the left side, and loosen the pinch bolt on the right side.
3. Remove the anchor arm nut and washer from the anchor stud, then remove the upper arm cap screws and remove the anchor arm.
4. Tap the axle out with a soft mallet while supporting the wheel with one hand, then remove the speedometer drive unit from the hub and allow the wheel to slip down and out of the forks.
5. Remove the brake side-plate and the thick and thin spacers from the hub.
6. Installation is in the reverse order of removal.
7. Position the thin spacer on the brake side of the hub, and the thicker spacer on the speedometer drive side. Mount the brake side-plate and the speedometer drive unit on the hub, and slip the axle into position from the right side.
8. Position the anchor arm on its stud and secure it with the anchor arm nut and washer, then tighten the upper anchor arm capscrews.
9. Position the axle washer on the axle with the chamfered side facing out and secure the axle nut. Remove the bike from the blocks and vigorously pump the forks to align the fork legs, then secure the pinch bolt.
10. Adjust the front brake as described in "Maintenance."



WHEEL BEARINGS

Removal and Installation



1. Remove the front wheel as described in the above section.
2. Drift out the dust cover from the opposite side of the hub, then pull the bearing out with Puller (H-D part no. 96729-63) or a suitable substitute, but only if replacement is necessary.
3. Remove the bearing spacer, invert the hub, and remove the other dust cover and bearing in the same manner.

4. Press the new bearing in place until it is seated against the hub shoulder, then press the dust cover into place against the bearing, after making sure the dust seal is in place in the cover.

5. Invert the hub and install the bearing spacer, then press the remaining bearing into place until seated against the spacer, and press the dust cover into place until seated against the bearing in the same manner as the first.

6. Mount the wheel and adjust the brake as described in the front wheel "Removal and Installation" section.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect the bearings for a worn, pitted, or damaged condition, or rough motion, and replace them as necessary. Always repack the open type bearings before installing them. (Late models have sealed bearings which require no attention.)

3. Inspect the dust seals inside the dust cover for a worn, dirty, or damaged condition, and replace them as necessary.

4. Inspect the brake shell and shoes for a worn, scored, grooved, glazed, or otherwise damaged condition and replace them as necessary as described in the "Brakes" section.

REAR WHEEL

Removal and Installation

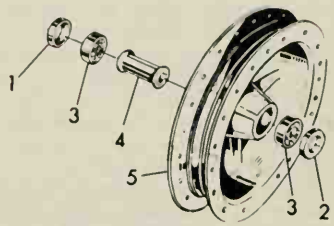
1. Block up the motorcycle so there is enough room to remove the rear wheel, making sure the machine is well balanced.

2. Disconnect the drive chain and wire it to the frame to prevent it from coming off the front sprocket.

3. Remove the brake adjusting nut and disengage the brake rod from the actuating lever, remove the brake anchor arm nut and washer, then slip the arm from the brake side-plate stud.

4. Remove the axle nut and washer, then tap out the axle with a soft mallet while holding the chain adjuster against the swing arm to prevent it from binding the axle. Allow the wheel to fall down between the forks and roll it clear.

5. Remove the brake side-plate and spacer.



6. Installation is in the reverse order of removal. Make sure the spacer washer is properly positioned between the side-plate and the hub.

7. Adjust the brake and chain as described in "Maintenance."

Removal and Installation

1. Remove the wheel as described in the above section.

Rear hub assembly.

1. Left Bearing Retainer
2. Dust Cover
3. Ball Bearing (2)
4. Spacer
5. Wheel Hub

2. Unscrew the bearing retainer, drift out the dust cover from the opposite side of the hub, and remove the bearing if necessary with Puller (H-D part no. 95760-69) or a suitable substitute.

3. Remove the bearing spacer, invert the hub, and remove the remaining bearing in the same manner as the first.

4. Press a new bearing into place until seated against the brake-side hub shoulder, then press the dust cover into place after making sure the dust seal is in place in the cover.

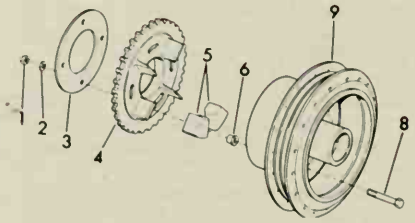
5. Invert the hub, insert the bearing spacer, press in the remaining bearing until seated against the spacer, and screw down the bearing retainer.

6. Install the rear wheel as described in the rear wheel "Removal and Installation" section.

Inspection

1. Consult the front wheel "Inspection" section.

REAR SPROCKET REMOVAL AND INSTALLATION



1. Remove the rear wheel as described in the rear wheel "Removal and Installation" section.

2. Remove the nuts, lockwashers, outer disc, and the sprocket, and then remove the rubber bushings, spacers, inner disc (if applicable), and bolts from the sprocket.

3. Clean all parts in a suitable solvent and blow them dry.

4. Assembly is in the reverse order of disassembly.

5. Insert the bolts through the hub, mount the inner disc on the hub bolts, insert the rubber bushings and spacers into the sprocket, mount the sprocket on the hub bolts with the shouldered side toward the hub, position the outer disc on the hub bolts with the chamfered side out, and secure the whole assembly with the hub bolts nuts and lockwashers.

BRAKES

M Models

DISASSEMBLY

1. Remove the wheel as described in the front wheel "Removal and Installation" section.

2. Disconnect the brake return springs and pull the shoes off at right angles to the side-plate.

3. Remove the operating shaftnut, washer, operating lever, and operating cam if so desired.

INSPECTION

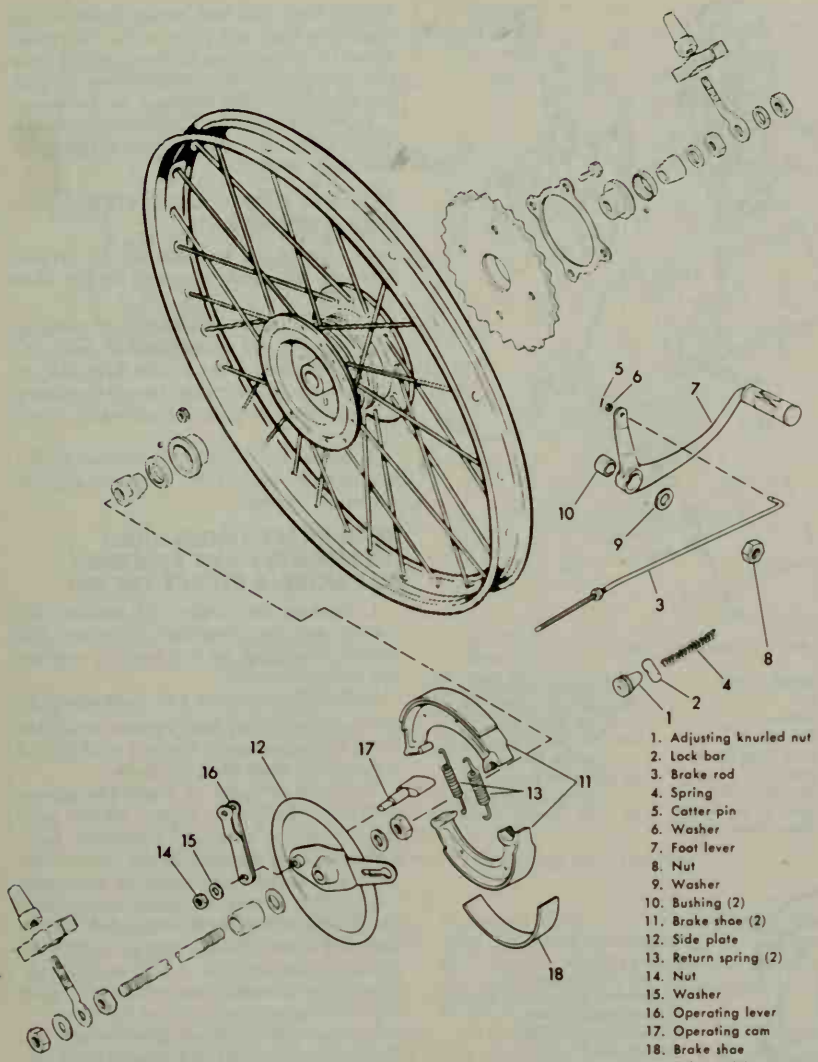
1. Clean all parts other than the brake shoes in a suitable solvent and blow them dry.

2. Inspect the brake shoes for a worn, glazed, oil-soaked, cracked, or otherwise damaged condition, and replace them as necessary. The shoes may be reused if only slightly glazed. Rough up the glazed surface of the shoes and drum with some medium grade sandpaper and blow them clean before reusing.

3. Inspect the remaining parts for a worn or damaged condition and replace them as necessary.

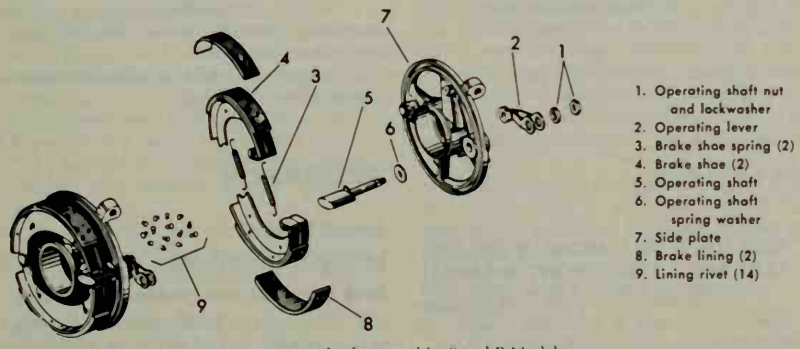
ASSEMBLY

1. Install the operating cam and lever, and secure them with washer and nut.



2. Hook the return springs into the shoe holes so that the spring hooks are facing the opposite direction on the same shoe, then fold the shoes and mount them on the operating shaft and pivot studs and press down on the shoes to unfold them onto the side-plate. Use a screwdriver if additional leverage is required.

3. Mount the wheel as described in the appropriate section.



REAR BRAKE CROSS-SHAFT DISASSEMBLY AND ASSEMBLY

1. Remove the brake adjusting knurled nut, lockbar, and brake rod spring, then remove the cotter pin and washer to free the rod from the brake pedal.

2. Remove the footlever mounting nut and washer, and pull the lever from the shaft. Both footrests are also mounted on

Brake and cross-shaft assembly.

Front brake assembly, S and B Models.

the shaft and can be removed at this time by pulling the shaft free of the frame.

3. Inspect the footlever bushings for a worn or damaged condition and replace them as necessary.

4. To assemble the cross-shaft, insert the shaft and both footrests, lightly grease the right-side end of the shaft, and mount the footlever.

5. Position the footlever so its under the foot rest, then secure the assembly with the washer and nut.

6. Install the brake rod assembly and adjust the brake as described in the "Maintenance" section.

S and B Models

DISASSEMBLY

1. Remove the appropriate wheel as described in the appropriate wheel "Removal and Installation" section.

2. Remove the operating shaft nut, lockwasher, and lever.

3. Pry the return springs from the shoes and remove the operating shaft and spring washer from the brake side-plate.

INSPECTION

1. Consult the M Models "Inspection" section.

2. New linings may be riveted onto the shoes as described in the Sprint "Inspection" section.

ASSEMBLY

1. Lay the brake side-plate on a bench with the outside face facing down.

2. Position the operating shaft spring washer on the shaft so the raised portion of the shaft seats against the shaft shoulder, and then insert the shaft into the side plate.

3. Place the shoes on the side-plate, connect them with the spring located nearest the pivot post, and attach the remaining spring.

4. Invert the side-plate and install the operating lever, lockwasher, and shaft nut.

5. Mount the wheel, and lubricate the brakes as described in the "Maintenance" section.

Sprint Models

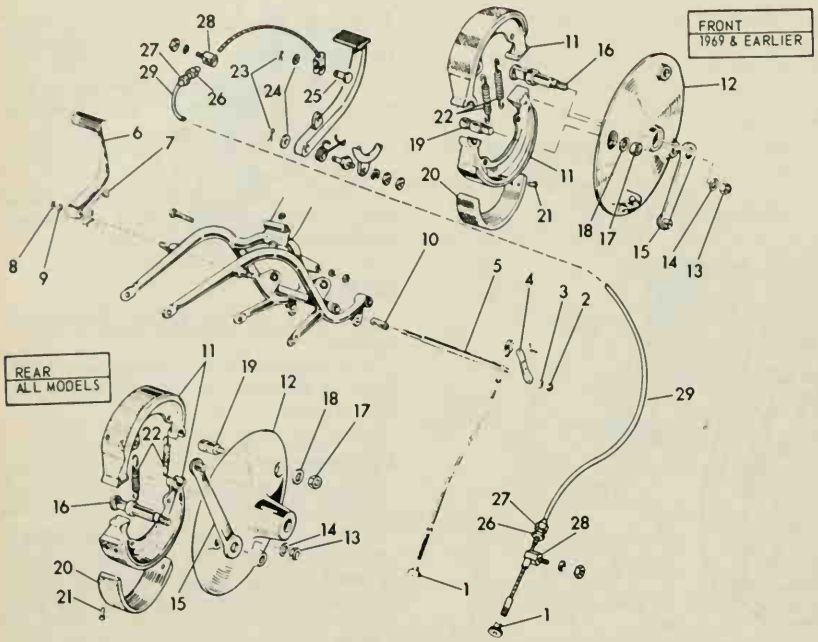
DISASSEMBLY (ALL MODELS EXCEPT 1970 AND LATER FRONT BRAKES)

1. Remove the wheel as described in the front wheel "Removal and Installation" section.

2. Pull the brake shoes from the brake side plate at a right angle from the plate, and disconnect the return springs.

3. Remove the operating shaft nut, washer, lever, and shaft, then remove the pivot stud nut, washer, and pivot stud.

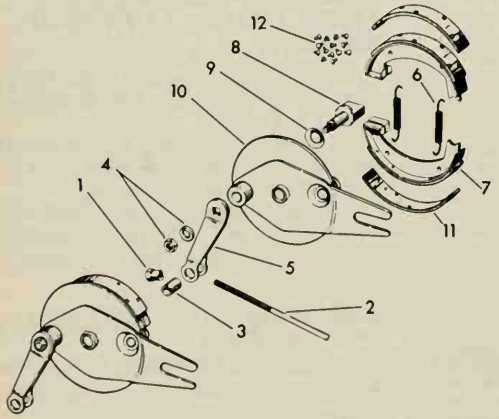
DISASSEMBLY (1970 AND LATER FRONT BRAKES)



1. Remove the wheel as described in the front wheel "Removal and Installation" section.

2. Remove the brake shoe lockrings with Snap-Ring Pliers (H-D part no. 96215-49) or a suitable substitute, remove the washers, and pull the shoes away from the operating shafts together and off the pivot studs with both shoes still attached by the return springs. Separate the springs from the shoes.

3. Remove the washers from the pivot pins and remove the operating levers if so desired. Mark the position of the lever slot on the splines with a small chisel mark so they can be reassembled in their original positions. The levers should be parallel and at right angles to the brake cable.



INSPECTION AND REPAIR

1. Consult steps 1–3 of the M Models "Inspection" section.

2. If the brake shoes are serviceable but the linings are shot, new linings can be riveted to the shoes, or new shoes with the linings already attached can be purchased.

3. Replace the brake linings in the following manner:

a. Install the center rivet first and then alternate the remaining rivets so the next one goes to the right of the first, to the left of the first, to the right, etc., so the lining is drawn down evenly.

b. The rivets may be set by hand or machine, and the end of the lining should be beveled in either case. The rivets should seat the linings tightly against the shoe.

ASSEMBLY (ALL MODELS EXCEPT 1970 AND LATER FRONT BRAKES)

1. Insert the pivot stud into the side-plate and secure it with the washer and nut.

2. Slip the operating shaft into the side-plate, mount the operating lever onto it so the large flats of the shaft and lever are at right angles to one another, secure the assembly with the washer and nut, and position the lever so it's pointing away from the anchor stud.

3. Attach the return springs to one of the shoes so the spring hooks are facing in the opposite direction from each other.

4. Connect the shoes together with the springs then fold and mount them on the operating shaft and pivot studs, then press down on them to make them unfold onto the side-plate. Use a screwdriver to gain the added leverage that may be necessary.

4. Mount the wheel as described in the appropriate rear wheel "Removal and Installation" section.

ASSEMBLY (1970 AND LATER FRONT WHEELS)

1. Assembly is basically in the reverse order of disassembly except for the shoe assembly.

2. Mount the shoes after lightly greasing the pivot pin and operating shaft ends. Position the shoes without attaching the return springs, then engage the springs using a screwdriver to gain the necessary leverage.

3. Install the wheel as described in the appropriate rear wheel "Removal and Installation" section.

REAR BRAKE CROSS-SHAFT DISASSEMBLY AND ASSEMBLY (ALL MODELS EXCEPT THE SS)

1. Remove the brake rod knurled adjusting nut, the cross-shaft lever nut and washer, then tap on the shaft to remove the lever.

2. Pull the footlever and shaft assembly clear of the frame, then remove the brake lever spring, securing nut and washer, and remove the shaft from the lever.

3. Clean all parts in a suitable solvent and blow them dry. Inspect all the parts for a worn or damaged condition, especially the fit of the shaft in the frame bushings, and replace any parts as necessary.

4. Lightly grease the frame tube, assemble the footlever to the threaded end of the shaft so the notches engage, mount the spring to the shaft so it will support the lever from beneath, and insert the shaft into the frame tube.

5. Mount the crossover shaft lever to the shaft while holding the footlever in its normal position, and draw the shaft lever into position by screwing on the mounting nut and washer.

6. Attach the footlever spring to the lever and secure the lever with the mounting nut and washer.

7. Adjust the brake as described in the "Maintenance" section.

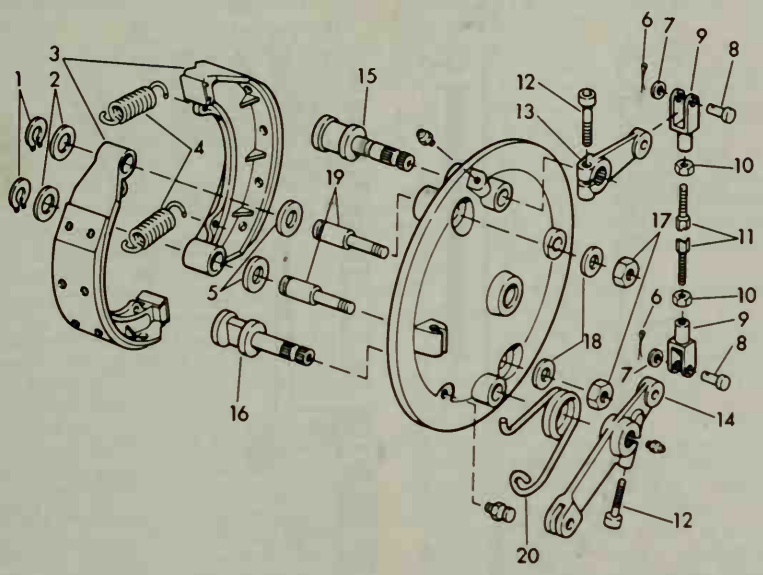
MODELS M AND MS

Fork Removal and Disassembly



1. Remove the front wheel as described in the Models M and MS front wheel "Removal and Installation" section.

2. Remove the front fender and drain the fork oil as described in the "Maintenance" section.

3. Loosen the lower bracket bolts and remove the legs by wedging a screwdriver into the bracket slot and pulling and twisting on the main tubes.

4. Disassemble the fork leg in the following manner:

a. Remove the oil seal from the top of

the leg, then remove the fork spring, spacer, lower spring, and the lower cover.

b. Pull the main tube from the slider assembly by sharply jerking them apart.

c. Remove the damper lockring, damper assembly, and the tire assembly tube seal.

5. Remove the headlight mounting bolt and allow the light assembly to hang down on the fork bracket.

6. Remove the speedometer drive unit from the end of the cable and remove the cable from the left fork, upper cover, cable loop, then remove the brake cable locknut and ferrule, and slide the cable out from the right fork upper cover cable loop.

7. Loosen the fork stem nut enough to relieve the tension on the upper fork bracket.

8. If the fork side is to remain assembled, loosen the fork plug several turns so the fork cover can be removed from the bracket assemblies. This will also allow the rubber ring and cap to be removed.

9. The covers are installed in the reverse order of removal.

Inspection

1. Before tearing into a fork because the action is poor, change the oil to eliminate the possibility of water contamination which might be the cause.

2. If this doesn't appear to be the problem, or if the fork leaks or is damaged, disassemble it as described in the above section, clean all parts in a suitable solvent and blow them dry, and inspect all the parts for a worn or damaged condition and replace them as necessary. Replace the slider if there is any appreciable play in the fit of slider and tube.

3. Inspect the fork stem and bracket, and the upper bracket for a damaged or misaligned condition. They must be replaced as directed in the "Fork Stem and Bracket Assembly Removal" section.

4. Check the fork tubes for a warped or out-of-round condition by first rolling them on a perfectly clean and flat surface to check for warping, and then slip them into a new slider if possible and work them up and down several times. If the tube is in serviceable condition, it will not bind at any point.

5. Tubes can be straightened unless they are severely bent. If the stem and bracket assembly or a slider is damaged, it must be replaced.

Fork Stem and Bracket Assembly Removal

1. Disassemble the forks as described in the "Fork Removal and Disassembly" section, then remove the fork upper covers.

2. Remove the handlebar clamp nuts, washers, spacers, U-bolts, and pads, then lift the entire handlebar assembly with the cables and levers still attached and place it out of the way. Try to avoid bending the cables any more than necessary.

3. Remove the fork stem nut and upper washer to free the upper bracket, remove the upper steering head cone while supporting the fork stem and bracket assembly, then remove the stem and bracket assembly while taking care not to lose any of the bearings. There are 23 bearings in each of the cups.

4. Remove the lower steering head bearing cone from the stem and bracket, and remove the head cups if necessary by tapping them out with a piece of bar stock inserted through the steering head. The cups should be removed only if worn, pitted, or otherwise damaged. If any of the bearings are lost, they must be replaced as an entire set.

Fork Stem and Bracket Assembly Installation

1. Assembly is basically the reverse of disassembly.

2. Pack the bearings in fresh grease in the head cups.

3. Tighten up the upper steering head bearing cone and then back it off a turn at a time until the steering action of the forks is as desired. The action of the head should be smooth and free.

4. Continue the assembly process as described in the following section.

Fork Assembly and Installation

1. Assemble the upper covers and forks in the reverse order of disassembly.

2. Wedge apart the fork bracket by inserting a screwdriver in the bracket slot, and force the fork side up through the brackets by twisting, pushing, and tapping with a soft mallet on the bottom of the leg.

3. When the upper tube is flush with the top of the bracket, fill the fork with oil as described in the "Maintenance" section.

4. Complete the assembly in the reverse order of disassembly.

MODELS ML AND MLS

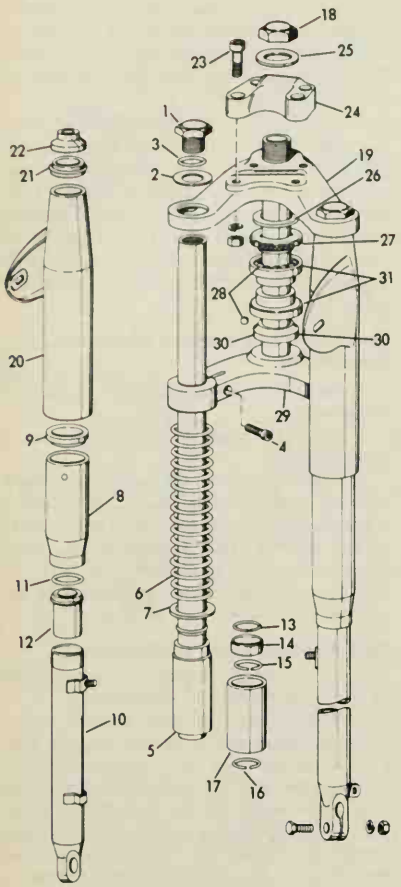
Fork Removal and Disassembly

1. Remove the front wheel as described in the Models ML, MLS, and MSR front wheel "Removal and Installation" section.

2. Remove the front fender and the upper plug and washer.

3. Loosen the lower bracket bolt and remove the legs by wedging a screwdriver into the bracket slot and then pulling and twisting on the main tubes to free them from the brackets. If the tubes won't come free, screw the upper plug in a couple turns and tap on it with a soft mallet. Invert the tubes and allow them to drain.

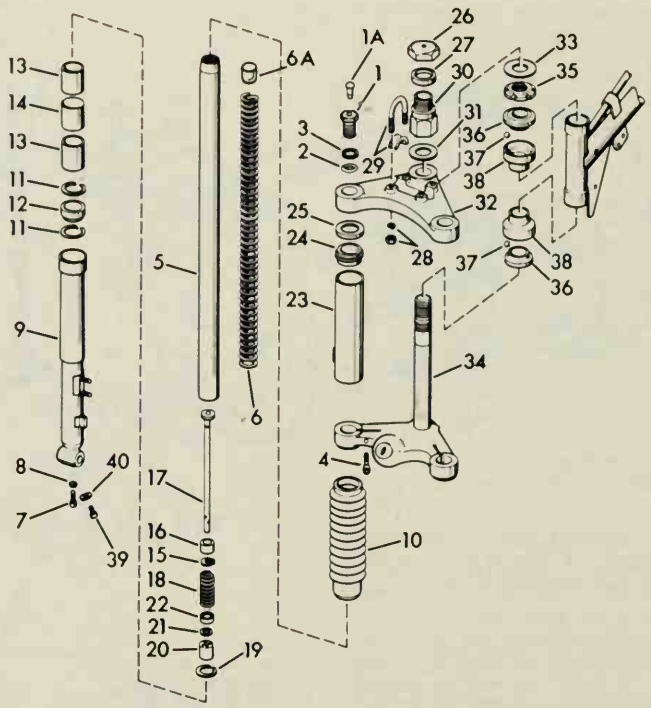
4. Disassemble the fork slides on 1969 and earlier models in the following manner:



a. Remove the fork spring and spring washer.

b. Secure the reinforced portion of the fork lower cover in a copper or wood-jawed vise and rotate the slider to the left to remove it. Slip the axle through the axle hole and use it as a lever to aid in removal.

c. Remove the main fork slide tube from the slider assembly by yanking on it sharply.



d. Remove the tube oil seal, O-ring, and the lower bushing, only if the need for replacement is indicated.

e. Remove the damper lockring, collar, upper and lower lockrings, and then

press the collar from the tube to complete the damper disassembly.

5. Disassemble the fork slides on 1970–71 models in the following manner:

a. Remove the fork spring and spacer (if applicable), the slider-to-tube screw and gasket, pull the slider assembly from the tube, and remove the boot (if applicable).

b. Invert the tube and tap on its surface with a soft mallet to free the damper valve assembly and buffer spring.

c. Disassemble the damper valve assembly by removing the lockring from the groove in the bottom of the damper tube.

d. Remove the valve components by slipping the damper tube assembly back into the fork tube, inserting a long rod into the tube, and tapping the rod with a hammer to force the valve assembly from the tube.

e. Remove the damper piston by removing the lockring with a pair of lockring pliers.

f. If the slider seal is in need of replacement, remove the upper lockring with a pair of snap-ring pliers and pry the seal from the slider.

g. If the slider bushing is in need of replacement, cut it carefully with a hacksaw blade, pry the bushing away from the slider wall with a suitable chisel, and grab the bushing with pliers and pull it out. There is a spacer between the two bushings which will also have to be removed.

6. Remove the headlight mounting bolt and allow the light assembly to hang down on the fork bracket.

7. Remove the speedometer drive unit from the end of the cable and remove the cable from the left fork, upper cover, cable loop, then remove the brake cable locknut and ferrule and slide the cable out of the right fork, upper cover, cable loop.

8. Loosen the fork stem nut enough to relieve the tension on the upper fork bracket.

9. If the fork side is to remain assembled, loosen the fork plug several turns so the fork cover can be removed from the bracket assemblies. This will allow the rubber ring and cap to be removed.

10. The covers are replaced in the reverse order of removal.

Inspection

1. Consult the Model M and MS "Inspection" section.

2. If the sliders have any appreciable play on 1969 and earlier models, inspect the inside of the slider bushings, the outside of the collar, and the inside of the slider.

Fork Stem and Bracket Assembly Removal

1. Disassemble the forks as described in the "Fork Removal and Disassembly" section.
2. Remove the handlebar clamp screws and the clamp, then lift the entire handlebar assembly with the cables and levers still attached, and place it out of the way. Try to avoid bending the cables any more than necessary.
3. Remove the fork stem nut and upper washer to free the upper bracket, remove the upper steering head cone while supporting the fork stem and bracket assembly, then remove the stem and bracket assembly while taking care not to lose any of the bearings. There are 23 bearings in each of the cups.
4. Remove the lower steering head bearing cone from the stem and bracket, and remove the head cups if necessary by tapping them out with a piece of bar stock inserted through the steering head. The cups should be removed only if worn, pitted, or otherwise damaged. If any of the bearings are lost, they must be replaced as an entire set.

Fork Stem and Bracket Assembly Installation

1. Assembly is basically the reverse order of disassembly.
2. Pack the bearings in fresh grease in the head cups.
3. Tighten up the upper steering head bearing cone and then back it off a turn at a time until the steering action of the forks is as desired. The action of the head should be smooth and free.
4. Continue the assembly process as described in the following section.

Fork Assembly and Installation

1. Assemble the upper cover and forks in the reverse order of disassembly.
2. Wedge apart the fork bracket by inserting a screwdriver in the bracket slot, and force the side up through the brackets.
3. When the upper tube is flush with the top of the bracket, fill the fork with oil as described in "Maintenance."
4. Complete the assembly in the reverse order of disassembly.

MODEL MSR AND 1972 MODEL MLS

Fork Removal and Disassembly

1. Remove the front wheel as described in the Models ML, MLS, and MSR front wheel "Removal and Installation" section.
2. Remove the headlight and bracket assembly (if applicable).
3. Remove the cap screws or anchor nuts to remove the front fender and brake side-plate anchor strap.
4. Loosen the fork bracket pinch bolts and pry a screwdriver upward into the bracket slot.
5. Remove the fork plug, washer, and seal, then screw the Fork Tool (H-D part no. 97305-61), or a suitable substitute, into the upper tube and strike it with a copper or lead mallet to drive the fork leg out of the brackets. Make sure the tool has seated before striking it, in order to protect the threads, and take care to keep foreign particles from falling into the tube.
6. Disassemble the fork slider tube in the following manner:
   a. Remove the fork spring from the top of the tube, invert the tube, and drain the fork oil from it.
   b. Remove the axle pinch bolt and the damper tube screw and its washer from the bottom of the slider assembly, then sharply pull the slider from the tube. Invert the tube to slide the damper out.
7. Disassemble the main tube in the following manner:
   a. Slip a 24 in. rod with a ⅛ in. diameter through the bottom of the tube until it engages the buffer spring, then push the buffer spring out of the tube.
   b. Remove the damper valve body lockring. It may prove necessary to notch the tube with a sharp instrument to get under the ring so that it may be pried from its groove in the tube.
   c. Insert a 24 in. rod with a ⅝ in. diameter into the tube until it seats on the damper valve washer, then strike the top of the rod with a hammer to drift the valve body from the tube. The damper valve and washer will also come free at this time.
8. Remove the damper piston lockring and piston from the damper tube.
9. Remove the fork boots, pull the slider free, and remove the tube seal lockring and the upper and lower oil seals from the slider.

Inspection

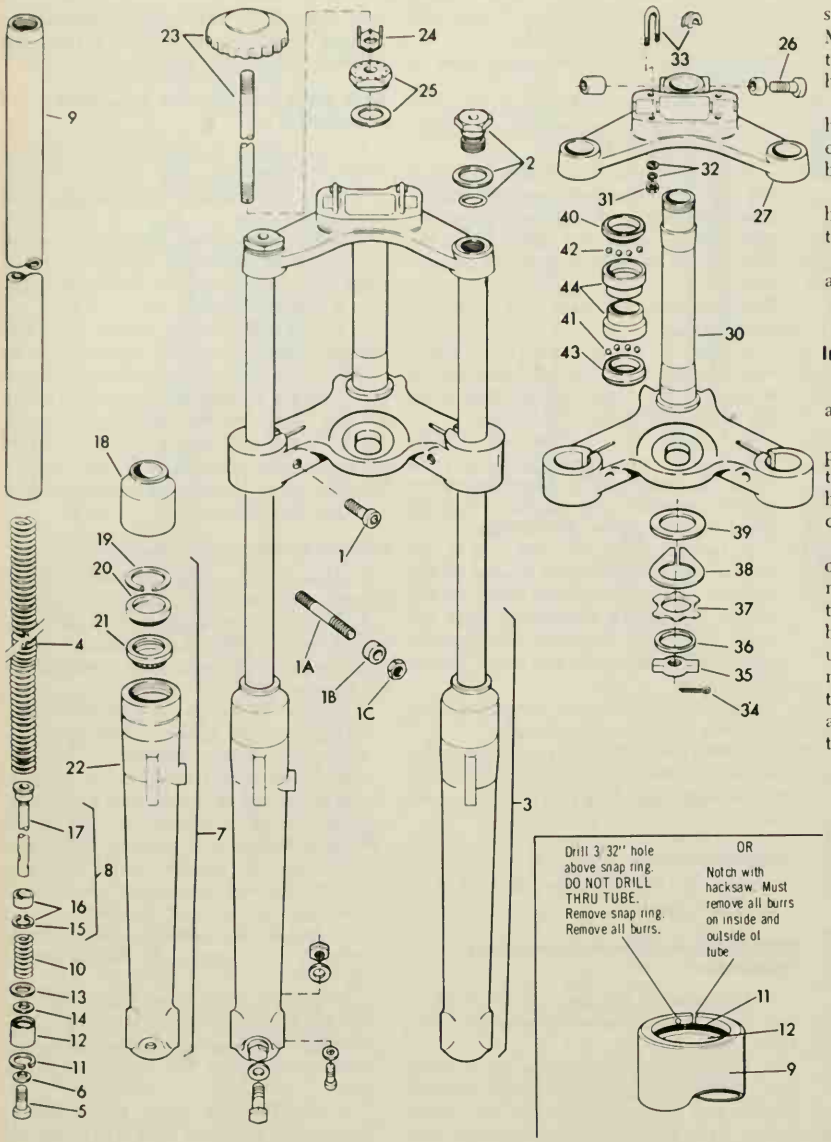
Consult the Models M and MS "Inspection" section.

Fork Stem and Bracket Assembly Removal

1. Disassemble the forks as directed in the "Fork Removal and Disassembly" section.
2. Disconnect and lift away the handlebar assembly with all the cable still attached and place it out of the way while taking care not to bend the cables any more than is absolutely necessary.
3. Remove the headlight assembly (if applicable).
4. Remove the damper assembly on MSR models by removing the steering damper rod cotter pin, unscrewing the damper rod assembly, and removing the steering damper lower nut, spring washer plate, spring washer, rod lock, anchor plate, friction disc, and the fork stem nut and washer.
5. Remove the fork upper bracket by placing a block of wood under the bracket and drifting the bracket up and off of the fork stem and bracket, then push the stem and bracket down through the upper bearing cone until the lower cone bearings are accessible for removal.
6. Remove and separate the bearings for replacement in their original positions. If any of the bearings are lost, or if the sets are mixed, both sets will have to be replaced.
7. Slip the stem and bracket down the rest of the way and remove and separate the upper bearings and cone, then remove the lower cone.
8. Remove the head cups if necessary by drifting them out with a piece of bar stock inserted through the steering head.

Fork Stem and Bracket Assembly Installation

1. Assembly is basically in the reverse order of disassembly.
2. Pack the bearings in fresh grease in the bearing cups.
3. Remove the play from the steering head cones by tightening the fork stem nut until the play is gone but the steering action is still smooth and free.
4. Check the steering action once the bike has been completely reassembled by blocking the front wheel off the ground and rotating it from side to side. Loosen the fork upper bracket bolt until the steering is the way you like it. There should be no appreciable play left in the fork. Secure the fork upper bracket bolt when satisfied with the fork motion.



Fork Assembly and Installation

1. Assemble the slider assembly in the reverse order of disassembly.
2. Assemble the damper tube assembly in the reverse order of disassembly.
3. Assemble the main tube in the following manner:
   a. Slip the smaller end of the buffer spring into the lower end of the tube until past the tube shoulder.
   b. Position the damper valve in its recess at the top of the damper tube body, place the valve washer on top of the body so the valve is covered, then carefully insert the washer end of the body into the bottom of tube and press it into place against the tube shoulder.
   c. Install the damper valve body lockring in its groove in the bottom of the tube.
   d. Slip the damper tube assembly into the tube at the top so it drops down through the damper valve assembly. Shaking the tube will help it find its seat.
   e. Slip the fork spring into position, then install the Fork Tool (H-D part no. 97305-61) in the top of the tube. Clean the tube thoroughly then insert the tube into the slider and compress the two until the damper tube snaps into position. Install and secure the damper tube screw and washer in the bottom of the slider.
4. Install the fork side in the brackets in the following manner:
   a. Install the Fork Tool then slip the tube and tool up through the brackets and pull the tube into place.
   b. Add the fork oil as described in "Maintenance," install the fork plug washer, seal, and plug, then secure the lower fork bracket pinch bolt.
   c. Complete the assembly in the reverse order of disassembly.
5. Install the steering damper (if applicable) in the reverse order of disassembly. The damper star washer should be dished side up on the damper rod assembly.

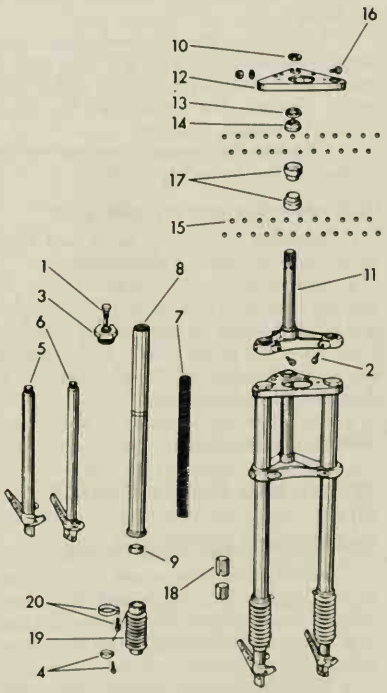
2. Remove the fork tube pinch bolts, headlight bracket, and fork outer tube caps, then wedge a screwdriver into the bracket slot.

3. Loosen the fork boot clamps and bolts and pull the sliders and springs from the outer tube.



4. Pry the oil seals from their seats with a screwdriver if replacement is necessary.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect the condition of all the components for wear or damage and replace them as necessary. The fork springs should be $12^{21}/_{64}$ in. long and must be replaced if collapsed shorter.

3. Inspect the sliders for a worn, scored, or damaged condition and replace them as necessary. If there is appreciable play between the tube and the slider bushing, the bushing and oil seal must be replaced using Fork Bushing Tool Set (H-D part no. 97030-54), or a suitable substitute, and then reamed until the bushing groove aligns with the flanged end of the fork tube.

Fork Stem and Bracket Assembly Removal

1. Disassemble the fork sides as directed in the "Fork Removal and Installation" section.

2. Disconnect the speedometer cable from the speedometer head, and free the head from the head from the fork upper plate, then disconnect the handlebars and shift them out of the way taking care to bend the cables no more than is absolutely necessary.

3. Remove the fork stem nut, loosen the upper pinch bolt, then carefully tap the stem and bracket from the steering head with a soft mallet. While the stem and bracket assembly is coming free, the fork upper plate, upper bearing guard, stem cone, and the bearings may also be removed. On the Hummer model, the ignition wires leading to the fork upper plate will have to be disconnected.

4. The head cups may be removed if replacement is necessary by inserting a piece of bar stock up through the opposite cup and tapping them out.

Fork Stem and Bracket Assembly Installation

1. Assembly is basically the reverse order of disassembly.

2. Mount the head cups and install the bearings along with a heavy coat of fresh grease.

3. Slip the fork stem into position, then install the fork stem cone and upper bearing guard. The fork upper plate can be tapped into place on the stem with a soft mallet.

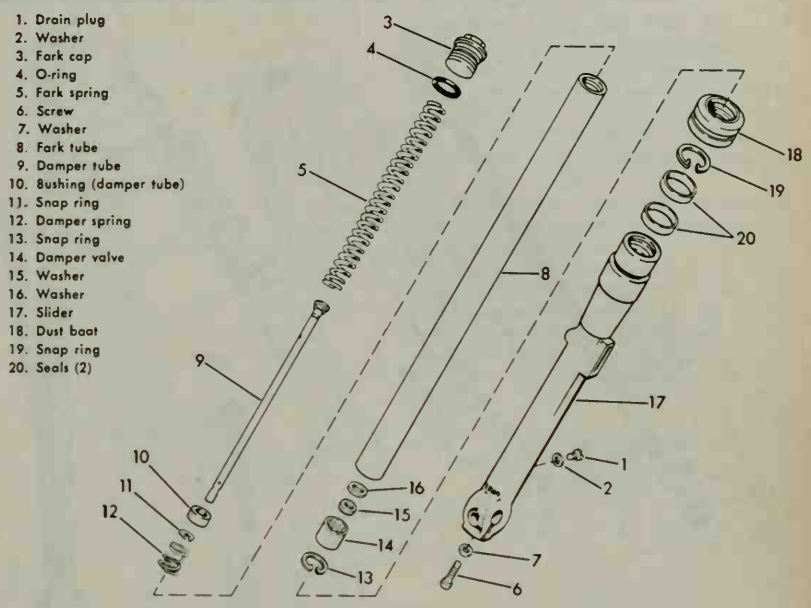
4. Tighten down the fork stem nut on the stem until all appreciable play has been removed, and so the motion of the stem is smooth and free.

5. Connect the ignition wires (Hummer models only), install the speedometer head, connect the cable, and complete the assembly in the reverse order of disassembly.

6. Once the front end has been completely assembled, recheck the motion of the forks. Loosen the upper plate pinch bolt and adjust the fork stem nut until the desired result is attained and then secure the pinch bolt. Install the fork panel, mount the headlight, and connect the wires as shown in the appropriate wiring diagram.

Fork Assembly and Installation

1. Assembly is basically in the reverse order of disassembly.



2. Install the outer tube oil seal.

3. Wedge a screwdriver in the fork bracket slot, slip the tubes into place until flush with the top of the bracket, install the tube caps, and secure the fork tube pinch bolts.

4. Install the fork boots and secure them with the clamps.

5. Screw the springs onto the threaded ends of the fork sliders, heavily grease the springs, and insert the sliders and springs into their appropriate fork tubes. Turn the sliders counterclockwise if necessary to properly align the slider fender attaching brackets. Secure the fork boots with the boot clamps and bolts.

6. Complete the assembly and lubricate the front end as described in "Maintenance."

ASSEMBLED VIEW

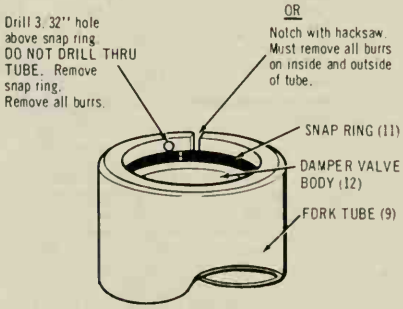
3 Loosen the lower fork bracket pinch bolt or stud nuts, and wedge a screwdriver into the bracket slot.

4. Remove the upper fork plug, screw Fork Tool (H-D part no. 97305-61) or a suitable substitute all the way into the tube until seated, taking care not to allow foreign particles to fall into the tube, and strike the tool with a copper or lead hammer to drive the tube from the brackets, or pull the fork leg out through the bottom.

5. Disassemble the fork side in the following manner:

a. Remove the fork spring from the top of the tube, then invert the tube and allow the fork oil to drain out.

b. Remove the axle pinch bolt and the damper tube screw and washer, then separate the tube from the slider with a sharp jerk.



c. Invert the tube and allow the damper assembly to slide out.

6. Disassemble the main tube in the following manner:

a. Slip a 24 in. rod with a ⅛ in. diameter through the bottom of the tube until it engages the buffer spring, then push the buffer spring out of the tube.

b. Remove the damper valve body lockring. It may prove necessary to notch the tube with a sharp instrument to get under the ring so that it may be pried from its groove in the tube.

c. Insert a 24 in. rod with a ⅝ in. diameter into the tube until it seats on the damper valve washer, then strike the top of the rod with a hammer to drift the valve body from the tube. The damper valve and washer will also come free at this time.

Removing the damper valve body snap ring.

7. Remove the damper piston lockring and piston from the damper tube.

8. Remove the clamps securing the fork boots on H Models. Rotate the fork lower cover ¼ turn counterclockwise, pull off the fork slider, and remove the lockring and oil seal on C Models.

9. Remove the fork upper cover assembly in the following manner:

a. Disconnect the headlight and allow it to hang down on the fork bracket.

b. Remove the speedometer drive unit from the cable end, and slip the cable out through the loop on the left fork cover. Disconnect the brake cable at the handlebars and slip the cable out through the loop on the right fork cover.

c. Loosen the steering damper knob until the tension is taken off of the damper rod lock, then loosen the fork stem nut and upper bracket bolt several turns each.

d. If one fork side is to remain assembled, loosen its fork plug.

e. Place a piece of wood under the upper bracket, and carefully drift the upper bracket up until the cover and rubber ring assembly is free to be removed.

Inspection

1. Consult the Models M and MS "Inspection" section.

Fork Stem and Bracket Assembly Removal

1. Consult the Model MSR and 1972 Model MLS "Fork Stem and Bracket Assembly Removal" section. Models SS and SX are equipped with steering dampers.

Fork Stem and Bracket Assembly Installation

1. Consult the Model MSR and 1972 Model MLS "Fork Stem and Bracket Assembly Installation" section.

Fork Assembly and Installation

1. Install the fork cover in the reverse order of disassembly, making sure the rubber ring and O-ring are held in place as the cover assembly is slipped into place.

2. Assemble the fork slider in the reverse order of disassembly.

3. Assemble the damper tube in the reverse order of disassembly.

4. Assemble the main tube and fork side as described in steps three and four of Model MSR and 1972 Model MLS "Fork Assembly and Installation."

5. On 1970 and later SS models (from serial no. 12216) and on 1971 and later SS and SX models, a vent valve and baffle assembly is used. If these parts require replacement, or if there is oil leakage from the fork sides on older models, a replacement kit is available which may be installed. Use all of the parts in the kit rather than only those which appear to be in need of replacement.

Shock Absorber Disassembly and Assembly

1. Remove the shock absorber locknuts (if applicable), then remove the mounting bolts and their associated apparatus, and pull the shock off of the upper and lower mounting studs.

2. Disassemble 1969 and earlier shocks by compressing them in a vise. The lower cover's lip should seat on the edge of one vise jaw, and the top mounting eye should seat on the other jaw. Cover the top cover to protect it, then compress the spring while holding the upper cover. When the spring is sufficiently compressed, remove the split retainer ring.

using Shock Compressor Tool (H-D part no. 97010-52A) and a suitable washer. Remove the split retaining ring when the spring is suitably compressed. If the tool is not available, the shock can be disassembled by having one person compress the spring while another removes the retainer ring.

4. Remove the lower cover (if applicable), the spring washer, the spring, and the upper cover (if applicable).

5. Replace the shock unit and any other components which are worn or damaged, then reassemble the shock in the reverse order of disassembly, taking care not to catch the lower cover in the split ring groove as this will cause the cover to bend.

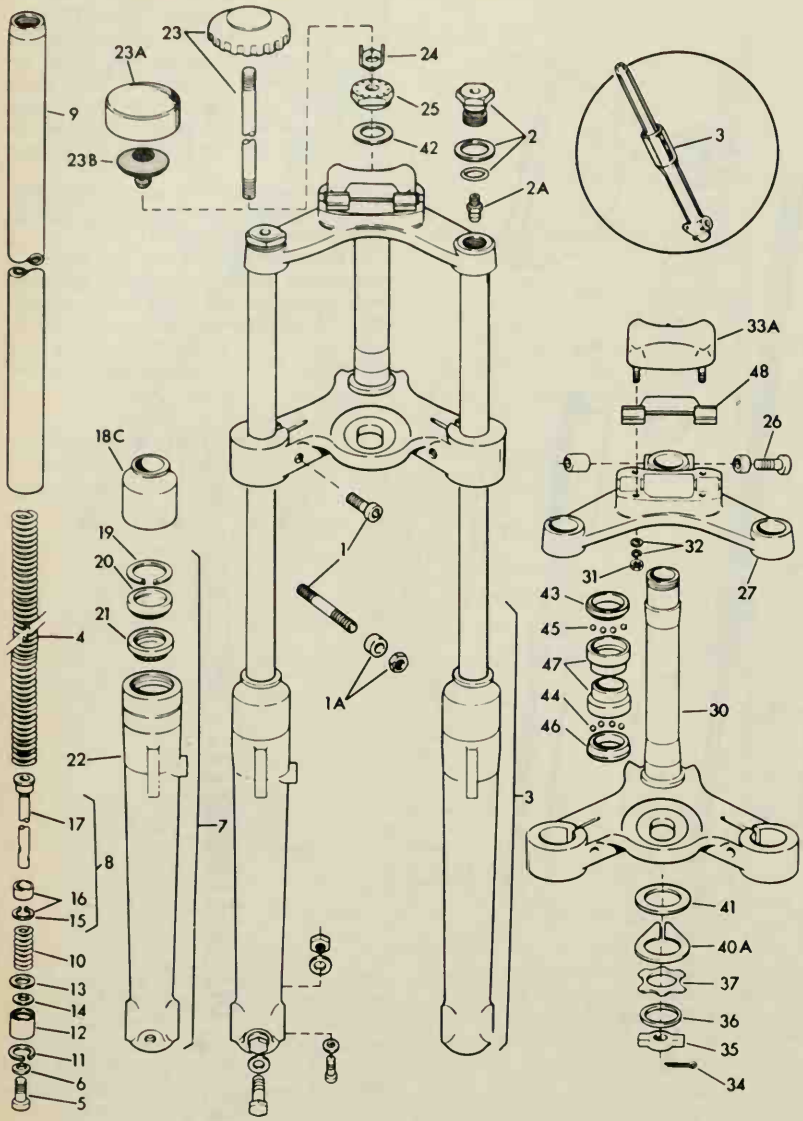
Rear Swing Arm Removal

1. Remove the rear wheel as described in the rear wheel "Removal and Installation" section.

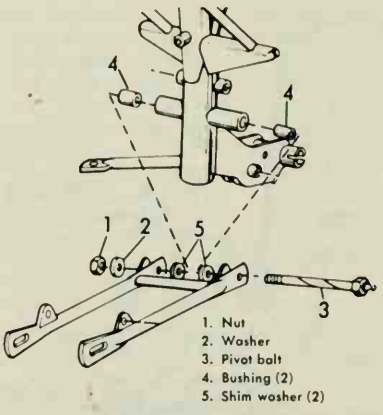
2. Remove the rear shock absorber as described in the above section.



3. Remove the pivot bolt nut, washers, and bolt on all M, MS, MC models.

4. Remove the rear brake lever and spring, then unscrew the pivot bolt and remove the bolt nut and washers on all MLS and MSR models.

Inspection



1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect the fit of the pivot bolt in the fork bushings for excessive play and re-

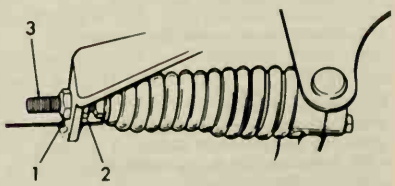
Rear swing arm for models M-50 and M-65

Rear swing arm for M-125

Rear Swing Arm Installation

1. Install the swing arm in the reverse order of removal.

2. Adjust swing arm side-play on M and MS models by loosening the pivot bolt locknut and tighten the pivot bolt until the play is minimal. Secure the locknut and lubricate the bushings with engine oil. The bushings should be lubricated every 1,000 miles.



3. Adjust the side-play on ML and MLS models by adding or removing the necessary amount of variable-thickness washers, which come in various thicknesses from 0.3 to 1.0 mm. Grease the pivot bolt at the grease fitting after the swing arm is assembled.

S AND B MODELS

Swing Arm and Spring Disassembly

1. Remove the muffler and its support tube, disconnect the rear brake rod, and remove the rear wheel as described in the rear wheel "Removal and Installation" section.

2. Remove the plug and nipple assemblies then drift the shaft out with a brass drift and hammer. Since shaft is secured in

Swing arm spring.

3. If the swing arm itself appears to be bent or damaged, it must be replaced since bending it back into shape may cause metal fatigue.

the frame with Grade C Locktite, the frame may have to be heated to loosen the Locktite.

3. Remove the thrust washers from between the fork and frame, then remove the spring stud nuts and pull the swing arm free.

4. Disassemble the swing arm springs in the following manner:

a. Pry the lockwasher ears to free them, remove the capscrews and caps, then slip the spring assembly free.

b. Remove the spring stud adjusting nuts from the studs, then remove the stud locknuts and washers.

c. Secure the cap on the cap body and place a rod through the hole between them to twist the spring off the cap body.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Check the bushings and shaft for wear, damage, or excessive play and replace them as necessary. Bushings are pressed in and out, then reamed with a ¾ (0.7500 in.) diameter expansion reamer.

3. Inspect all parts for a worn or damaged condition and replace them as necessary. If the swing arm is bent, sprung, or otherwise damaged, it must be replaced.

Swing Arm and Spring Assembly

1. Assembly is basically the reverse order from disassembly. All parts which are to be coated with Locktite must be thoroughly cleaned in an oil-free solvent.

2. Assemble the fork spring in the reverse order of disassembly.

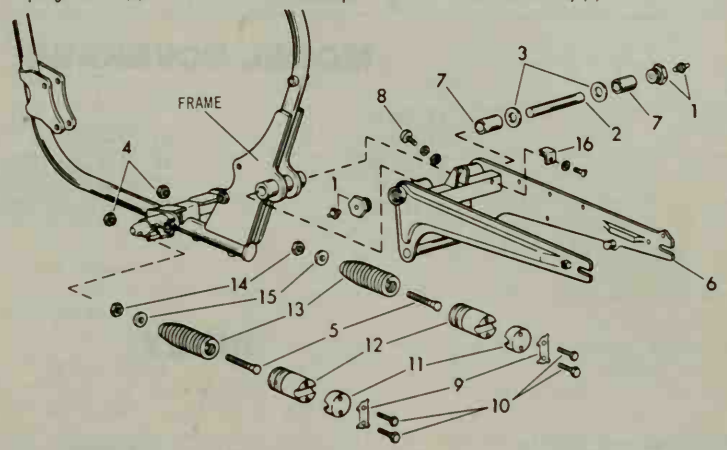
3. Position the swing arm in the frame so the rubber stop is facing up, then screw the adjusting nuts on the spring studs.

4. Coat the center of the fork support shaft with Grade C Locktite, leaving about 1½ in. clean on each end of the shaft.

5. Position the swing arm so the shaft holes are in alignment, then start the shaft into the holes. Before the shaft passes from the frame to the swing arm, position a thrust washer between the two. When the shaft has passed through the frame, washer, and swing arm, position another thrust washer on the other side and pass the shaft through it.

6. Coat the threads of the end plugs with Grade C Locktite before assembling them. Grease the swing arm through the plug nipples immediately after the plugs are installed to displace any Locktite which may have gotten on the bushings.

7. Complete the assembly in the reverse order of disassembly.



8. Adjust the spring tension by loosening the adjusting nut to decrease spring tension and by tightening it to increase the tension.

SPRINT MODELS

Rear Swing Arm Removal

1. Remove the rear wheel as described in the rear wheel "Removal and Installation" section.

2. Remove the rear shocks as described in the above section.

3. Remove the crossover shaft nut and washer on models C and H, then tap on the shaft end with a soft mallet until the brake operating lever is free of the shaft.

4. Bend back the pivot bolt lockwasher ear and remove the pivot bolt nut and lockwasher, then tap out the bolt with a brass drift.

5. Remove the swing arm assembly and the thrust washers from between the frame mounting ears.

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect all parts for a worn or damaged condition and replace them as necessary. If the swing arm is bent or damaged, it must be replaced.

3. Inspect the fit of the pivot bolt and the swing arm bushings for excessive play and replace them as necessary. Replace the bushings by drifting them out and pressing in the replacements. Ream new bushings with Reamer (H-D part no. 94810-65) or a suitable substitute.

Rear Swing Arm Installation

1. Install the anchor arm nut, bolt, and washer but do not tighten them down until the rear wheel has been installed and aligned.

2. Position the swing arm between the frame mounting ears with the anchor arm on the right side of the frame. Make sure the chain is over the swing arm and not behind it.

3. Hold the left-side thrust washer in place between the frame and swing arm, and slip the pivot bolt into position part way. Hold the right-side thrust washer in place and push the pivot bolt the rest of the way through.

4. Rotate the pivot bolt until the locating lugs on the pivot bolt's left end are in alignment with the mounting ear notches, then position the lockwasher so the bent prong seats in the groove in the frame, and mount and secure the pivot bolt nut. Secure the nut by bending the lockwasher ear up against the nut.

5. Check the motion of the swing arm for excessive play or too tight a fit which is indicated by binding, and adjust the play by adding or removing the spacer washers. Variable-thickness thrust washers are available in assorted sizes from 0.6–1.2 mm.

6. Lubricate the swing arm assembly by greasing the pivot bolt grease fitting until grease comes out from both bushings.

7. Mount the brake crossover shaft lever on the crossover shaft and secure it with a nut and lockwasher.

8. Mount the shock absorbers, carefully mounting the right shock so the brake rod is on the inside.

9. Mount the rear wheel as described in the rear wheel "Removal and Installation" section.

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*

LUBRICATION

Changing Engine Oil

1. Run the engine until normal operating temperature is reached.
2. Position the motorcycle so that it will stand straight up or lean slightly to the right.
3. Remove oil filter cap and drain plug in oil tank. Turn the engine over a few times to remove any oil remaining in the sump. It is not necessary to drain the crankcase as there is only a small amount of oil remaining.
4. Install drain plug. Pour one quart of kerosene into the oil tank. Rock the motorcycle gently from side-to-side. Remove drain plug and drain kerosene from oil tank.
5. Clean oil filters thoroughly and dry by blowing them with compressed air.
6. Reinstall drain plug and add proper quantity and grade of oil.

Changing Transmission Oil

SPORTSTER

1. Stand the motorcycle upright and remove the oil level plug from the chaincase bottom.
2. Fill the transmission through the large screw hole in the chaincase cover with engine oil until overflow begins from the oil level plug hole.

GLIDE MODELS

1. Remove the transmission oil filler plug to check level. The motorcycle must be standing upright.

2. Remove the drain plug to change the oil.

3. Refill with oil to the level of the filler opening.

4. Change the oil annually or every 5,000 miles.

Changing Fork Oil

FL/FLH

It is not necessary to change the fork oil unless leakage has been noted.

1. On non-adjustable forks, remove the upper bracket bolt at the very top of each fork tube.

2. On adjustable forks, remove the fork cover side panels or headlight housing and fork filler screws.

3. Remove the drain bolts from the bottom of the sliders, pumping the forks up and down to remove all the oil.

4. Refit the drain plugs and fill each fork leg with 6½ oz of Harley-Davidson Type B fork oil. Add 7 oz if the forks have been disassembled.

5. Refit the bracket bolts or filler screws.

FX/FXE

It is not usually necessary to change fork oil unless leakage has been noted.

1. Remove the front wheel and fender.

2. Remove the cap from the top of each fork tube. Remove the drain plugs from the fork sliders.

3. Loosen the bolt at the very bottom of each slider a few turns. Move the sliders up and down to drain all the oil.

4. Secure slider bolts and drain plugs. Fill each fork tube with the correct quantity of Harley-Davidson Type B fork oil. For 1972 and earlier models: 5½ oz. For 1973 and later models: 5 oz.

Add 1 oz to the above quantities if the forks have been disassembled.

SPORTSTER

On 1972 and earlier models, it is not necessary to change the fork oil unless leakage has been noted.

On 1973 and later models, change fork oil every 5,000 miles.

Refer to the FX/FXE section preceding for procedures. Oil type and quantity are the same for the Sportsters 1970 and later.

For 1968–69 models, add 4½ oz to each leg.

For 1967 and earlier models, add 3½ oz to each leg.

Add 1 oz extra if adding oil to forks which have been disassembled.

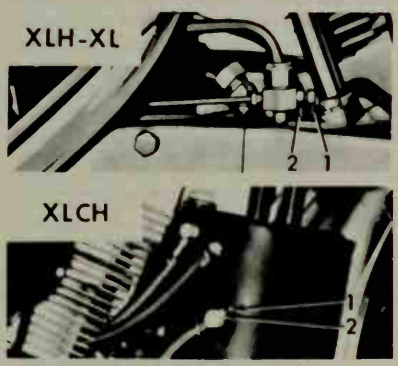
Primary Chain Lubrication

SPORTSTER

The Sportster's primary chain is automatically oiled through a port between the chain and transmission compartments.

GLIDE MODELS

Oil is supplied to the primary drive chain through an oil line which is connected to metering orifice in the oil pump.



Drive Chain Lubrication

1. Loosen the oiler screw locknut (if fitted) and turn the adjusting screw to the right to decrease flow, and to the left to increase flow.

NOTE: *It is important that the screw is never moved more than a fraction. Small adjustments make a great difference in oil flow.*

2. Hold adjusting screw with screwdriver and tighten locknut.

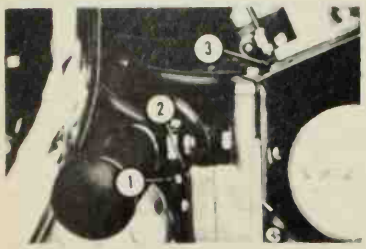
3. Check for proper rate of flow. Oil should be deposited on chain at the rate of two or three drops a minute.

Sportster drive chain oiler (early)

1. Adjusting screw
2. Adjusting screw lock nut (early 1970)

Chain Oiler Maintenance

1. The primary chain oiler (Glide models) needs no attention under normal conditions. If the chain oiler will not pass oil, it is probably clogged. Remove the orifice screw and washer from the oil pump and blow out the passage with compressed air.



2. The drive chain oiler should be checked every 2,000 miles.

3. If an oiler screw locknut is fitted, back it off as far as possible. Turn the screw in, counting the number of turns before it reaches its seat.
4. Remove the screw. Blow out the line with compressed air.
5. Install the screw, turn it in until it contacts the seat, then back it off the number of turns which were counted (Step 3). Tighten the locknut, if fitted.
6. Normal setting is ¼ turn open (Glide) and ¾ turns open (Sportster).

SERVICE CHECKS AND ADJUSTMENTS

Fuel Strainer

The fuel strainer is located in the top of the supply valve inside of the fuel tank. The strainer can be cleaned in the following manner:

1. Drain the fuel tank.
2. Remove the supply valve.
3. Remove the dirt lying at the lip of the hole where the supply valve was removed.

4. Clean strainer and blow dry with compressed air.
5. Replace the supply valve.

This operation should be performed every 2,000 miles or when needed.

Fuel petcock (1974 and earlier)

NOTE: *On 1975 and later valves, be sure it is set to the "off" position when the engine is not running.*

Air Cleaner

The metal mesh-type filter need never be replaced, but should be cleaned every 1,000 miles in a safe solvent and lightly coated with engine oil. For *extremely* dusty conditions, this should be performed every 100 miles or at least once a day.

The corrugated paper-type element should be blown free of dirt every 1,000 miles, or more often in dusty conditions. If the surfaces are oily or sooty, the element can be cleaned with a safe solvent. When the element ceases to come clean, it must be replaced. Never coat it with oil.

The plastic foam-type element uses oil in the same manner as the metal mesh air cleaner and requires service at the same intervals. A sooty surface is normal but when the surface pores become clogged or the surface becomes mottled, cleaning is necessary. Remove the filter from the screen and wash it in a nonflammable solvent. When completely dry, soak it in engine oil, work the oil in until it is an even color, and allow the excess to drain off. The filter is now ready to be replaced. Replace the element so that the three grooves are towards the screen.

Clutch Adjustment

GLIDE MODELS

Foot Control Adjustment

1. Remove chain housing cover.
2. Place the foot pedal in the fully engaged position (toe down).
3. Loosen the pushrod adjusting screw locknut, and turn the adjusting screw until the end of the clutch release lever has about ⅛ in. free-play before the clutch disengages. Turning the screw to the right will decrease the movement and to the left will increase the movement.
4. Secure the locknut while holding the adjusting screw with a screwdriver and recheck the adjustment.
5. Check that there is ¼ in. clearance between the lever and the starter drive housing.
6. The foot pedal should clear the bearing cover to prevent the rod from bending.

Hand Control Adjustment

1. Loosen the adjusting sleeve until there is about ¼ in. free movement at the hand lever before disengagement begins.
2. Turn the sleeve out for less lever play, or in for more, and secure the locknut.
3. If the above steps fail to correct the problem, or if the sleeve has already been adjusted all the way out, go on to the following steps.

2. Sleeve lock nut
3. Bracket
4. Clutch push rod adjusting screw lock nut
5. Clutch adjusting screw
6. Clutch spring adjusting nuts
7. Starter motor
8. Clutch release lever

4. Move the clutch release lever until all the slack in the actuating mechanism has been taken up. You will notice a difference in lever motion.

5. If, at this point, there is not ⅜–⅝ in. between the lever and the starter motor, take the following steps.

a. Loosen the sleeve locknut and turn the sleeve to the right until it is resting against the locknut.

b. Remove the clutch cover and loosen the pushrod locknut. Turn the adjusting screw clockwise to move the release lever backward, or counterclockwise to move it forward.

c. Secure the locknut while holding the adjusting screw with a screwdriver when the lever is about ½ in. from the starter motor.

d. Secure the clutch cover using a new gasket and a gasket sealer.

6. Repeat Steps 1 and 2 to complete the adjustment.

Hand Lever Cable Removal and Installation

1. Turn the adjusting sleeve to the right until it seats against the locknut.

2. Remove the cable by lifting the ferrule clear of the anchor pin and sliding it through the slot.

3. Replace with the pin slot toward the inside.

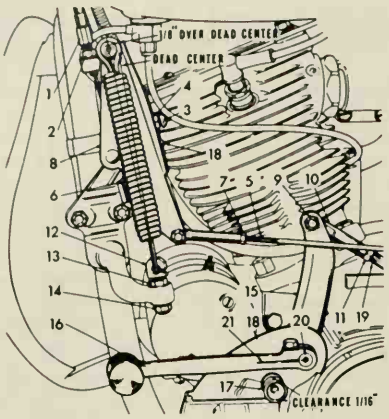
4. Replace pin-type assemblies with the open end facing down.

Hand Clutch Booster Control Adjustment

The routine adjustment that is made to maintain the correct amount of hand lever play is done in the following manner:

1. Loosen the control-coil adjusting sleeve locknut and turn the adjusting sleeve to the right until there is one or more inches of play at the hand lever.

2. Loosen the bellcrank adjusting screw locknut and turn in the adjusting screw until the bellcrank will no longer cross top dead center when shifted by hand.



3. Loosen the upper adjuster nut which controls the tension of the clutch booster spring. Loosen it all the way.

4. Slowly turn out the bellcrank adjuster screw and repeatedly check the release position that the crank will assume—moving it by hand—until it remains over top dead center. The crank should reach the end of its travel at about ⅛ in. over top dead center. Secure with the locknut.

5. Adjust the clutch rod until the release lever has about 1/16 in. play, and secure the locknut.

6. Back off the adjusting sleeve until the clutch hand lever has about ½ in. play before the clutch begins to release and then secure the locknut.

7. Pull in the clutch hand lever to its stop and tighten the lower adjuster nut for the booster-spring tension until the hand lever remains in. Slowly loosen the nut until the lever returns to the fully extended position.

8. Secure the upper adjuster nut which controls the tension of the booster spring.

The following procedure may help to eliminate hand lever stiffness, failure of the bellcrank to resume its position, or slipping or dragging of the clutch.

1. Back off the clutch lever rod locknut and adjust the rod until the actuating lever has about ½ in. of play.

2. Move the actuating lever forward until all slack is taken up.

3. Check and make sure that there is a ¼ in. clearance between the lever rod and chain housing.

SPORTSTER (1970 AND EARLIER)

Clutch Cable and Release Mechanism Adjustment

1. Loosen the locknut on the sprocket cover.

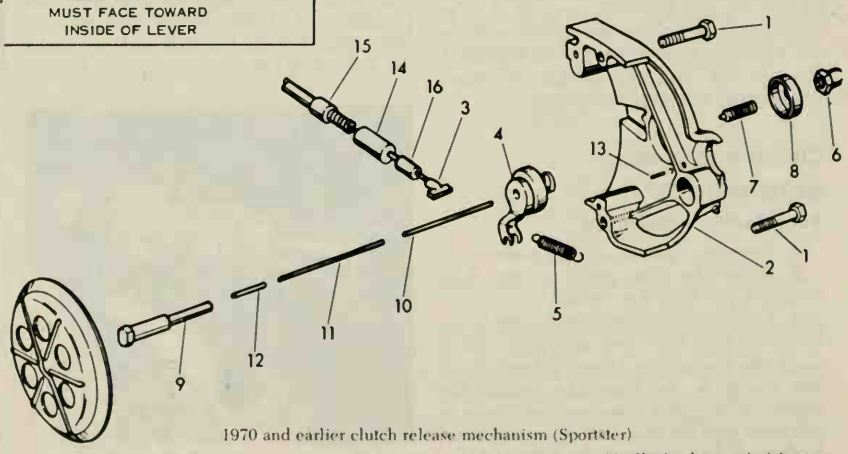
2. Insert a screwdriver and turn the clutch adjusting screw counterclockwise.

3. Placing the hand lever in the fully extended position should seat the releasing worm inside the sprocket cover.

4. Check the cable for binding within its housing if the hand lever doesn't fully return to its seat.

5. Turn the cable adjusting sleeve at the hand lever until the worm almost reaches its stop.

6. Turn the adjusting screw clockwise until there is play in ⅛ of the hand lever's total movement. This is indicated by slightly increased tension on the lever as it approaches the released position.



7. While holding the adjusting screw steady, secure the locknut. Test-ride the motorcycle to check for slipping or dragging.

Clutch Spring Adjustment

1. Disconnect the battery ground wire from the negative terminal on XLH models.

2. Remove the left footrest and rear brake lever from their splined shafts.

3. On 1966 and earlier models, remove the stoplight switch from its mount, without disconnecting the wires, and place it out of the way.

4. Place a drip pan under the chain cover and remove the cover and gasket.

5. Remove the clutch cover screws, retainers, cover, and gasket. Tap the cover gently to remove it, but do not pry on it as this may warp it and cause leaks.

6. Tighten the adjusting nuts, one-half turn at a time, making sure that they seat in their locked position against the adjusting plate after each turn. The nuts have hex-heads of 7/16 and ½ in. sizes.

7. When properly adjusted the pressure plate should be uniformly 3/16 in. from the outside of the spring cup flanges.

8. If tightened beyond 7/64 in. clearance, the clutch will not release. The necessity of such an adjustment would indicate worn or oily clutch plates. Excessive tightness will damage the clutch release rods.

SPORTSTER (1971 AND LATER)

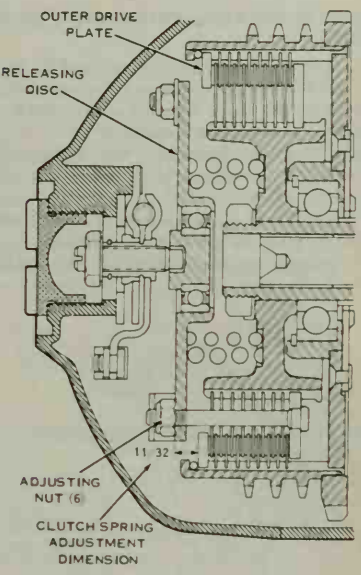
Clutch Cable and Release Mechanism Adjustment

1. Turn the cable adjuster in until there is a goodly amount of play in the cable.

2. Remove the plug from the primary chain compartment cover. Loosen the adjusting screw locknut and turn the adjusting screw in until resistance is felt. Turn it in about 2 more turns.

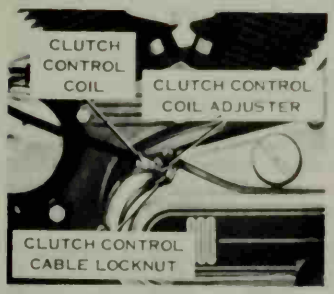
3. Turn the cable adjuster out until there is no free play (but no tension) in the cable. Tighten the cable adjuster locknut. The cable is now properly adjusted.

4. Back off the adjusting screw until it turns easily. Turn it in gently until resistance is felt, then back if off ¼ to ½ turn and tighten the locknut.

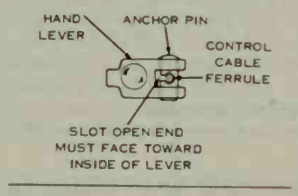


5. Check clutch operation and reset if necessary.

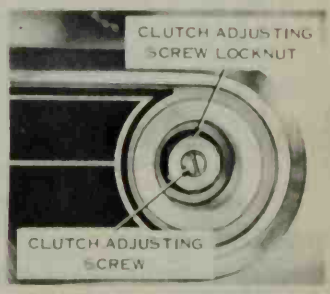
Clutch Spring Adjustment: 1971–Early 1974



1. The procedure is essentially the same as described for 1970 and Earlier Sportster.



2. When properly adjusted, the pressure plate should be 11/32 in. from the outer surface of the outer drive plate.



3. If tightened beyond 5/16 in. clearance, the clutch will not release. Such an adjustment will damage the clutch release rods.

Clutch Spring Adjustment: Late 1974 and Later

1. Clutch spring tension is fixed by the length of the six clutch stud spacers. As clutch plates wear, compensate by fitting shorter than standard spacers.

2. Clearance between the releasing disc and outer drive plate must not be less than ⅛ in.

3. Standard spacer length is 1.530 in. Shorter lengths are 1.440 and 1.450 in. All spacers in use must be the same length.

Clutch adjustment (late 1974 and later)

Brake Adjustments

ADJUSTING FRONT BRAKE CABLE (ALL MODELS)

1. Loosen the adjusting sleeve locknut.

2. Turn the adjusting sleeve locknut clockwise for less play (free movement) and counterclockwise for more play.

3. When there is about 3/16 in. cable play, or when ¼ of the brake lever's movement is free, tighten the adjusting sleeve nut. The wheel should be able to spin freely; if it doesn't, the shoes must be centered (adjusted).

ADJUSTING FRONT BRAKE SHOES (ALL MODELS)

1. Raise the front wheel so it may rotate freely.

2. Loosen the brake shoe pivot stud nut and sleeve nut. (Substitute "brake shoe pivot stud" for "pivot stud nut" on Sportsters. Loosen this but do not remove it).

3. Spin the wheel and apply the brake. Tighten the pivot stud nut and then the axle sleeve nut.

4. Recheck for correct cable adjustment.

ADJUSTING REAR WHEEL BRAKE LINKAGE

Sportster and Mechanical Brake Glide Models

1. Turn the brake rod adjusting nut clockwise to tighten the brake and counterclockwise to loosen it. The nut has a lip which serves as a stop against the clevis pin in the operating lever. Using a screwdriver as a lever against the brake operating lever, pry it forward, and turn the adjusting nut. This saves wear on the nut's lip.

2. There should be 1¼ in. of play in the brake pedal before the brakes begin to operate. If the brakes still drag, center the shoes.

HYDRAULIC DRUM BRAKE

1969 and Earlier

1. Expose the piston pushrod link by sliding the rubber boot away from the master cylinder.

2. Adjust the piston rod so that the foot pedal moves freely about 1½ in. before the brake begins to operate.

3. Back off the locknut and turn the plunger clockwise to shorten the pushrod, and counterclockwise to lengthen it.

4. Test for free movement and secure the locknut.

1970 and Later

1. Freeplay of the brake pedal (before the pushrod contacts the piston in the master cylinder) should be about 1/16 in.

2. If adjustment is necessary (FL/FLH), loosen the master cylinder rear bolt and brake pedal stop plate bolt. Move the front end of the plate down to decrease freeplay, up to increase it.

3. On 1972 and Later FX models, adjust by loosening the rod locknut and turning the rod to obtain proper play.

ADJUSTING REAR BRAKE SHOES

Sportster and Mechanical Brake Glide Models

1. Loosen the brake pivot stud and axle nuts but do not remove stud.

2. Rotate the rear wheel and operate the pedal while the wheel is spinning.

3. Tighten the pivot stud nut and then the axle nut.

4. Recheck for correct pedal adjustment.

HYDRAULIC DRUM BRAKES

1. Raise the rear wheel off the ground.

2. Turn the front brake cam adjusting nut (leading shoe) counterclockwise until the wheel begins to drag. Rotate the wheel in both directions.

3. Turn the nut clockwise until the wheel turns freely.

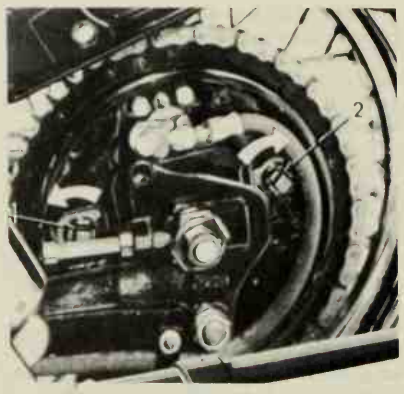
4. Repeat the procedure with the rearmost cam nut (trailing shoe), turning it clockwise to create the drag (Step 2), and counterclockwise to remove it.

HYDRAULIC DISC BRAKES

The hydraulic disc brakes are self-adjusting. Fluid levels in front and rear master cylinders should be checked every 1,000 miles.

Primary Chain Adjustment

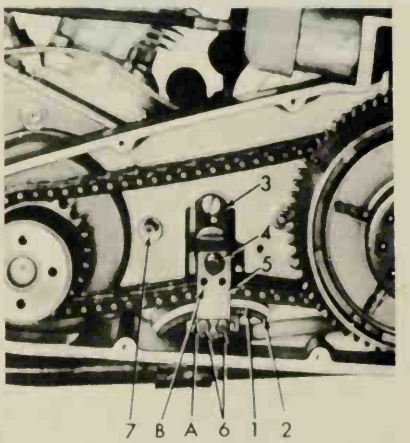
Check the primary chain every 2,000 miles for correct adjustment. Chain adjustment can be checked through the oil filter opening which is located near the top of the chain housing cover. A properly adjusted chain will have free up-and-down movement in the upper strand as follows:



Chain slack with cold engine—⅝ to ⅞ in.

Chain slack with warm engine—⅜ to ⅝ in.

To adjust the chain, follow the steps below.



1. Disconnect battery cable from starter motor. Remove left foot rest and rear brake foot lever.

2. Place an oil drain pan under clutch. Remove front chain cover screws, chain cover and gasket.

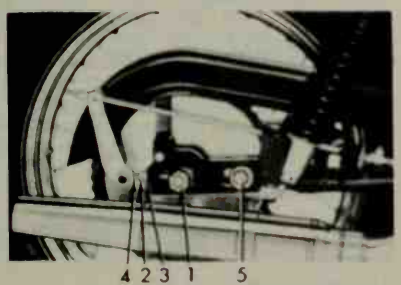
3. Loosen the chain adjusting shoe retaining bolts (three bolts on the Sportster, the backplate center bolt on Glide models). Raise shoe to tighten chain and lower to loosen chain.

4. Tighten retaining bolts. Check adjustment of chain.

5. Replace gasket, chain cover and secure with front chain cover screws. Reconnect battery cable to starter motor. Replace foot rest and brake lever.

Sportster primary chain adjustment



1. Drive chain
2. Chain adjuster shoe
3. Support bracket
4. Support bracket bolts (2)
5. Support bracket brace
6. Brace bolt

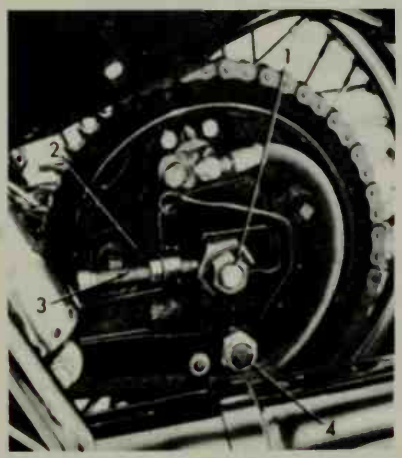
Rear Chain Adjustment

Check the rear chain adjustment every 1,000 miles. A properly adjusted rear chain will have a ½ in. movement midway between the mainshaft and the rear wheel drive sprocket. Adjustment should be checked at several points along chain. Chain is adjusted as follows:

Sportster

1. Loosen the axle nut.
2. Loosen the right and left adjusting stud locknuts. Loosen the anchor bolt on 73 models.
3. Turn both adjusting stud locknuts clockwise the same number of turns to tighten the chain and counterclockwise to loosen it. While loosening the chain, tap the axle forward with a soft mallet.
4. Secure the locknut against the adjusting nut and measure the distance from the locknut to the outer end of the adjusting stud. Both should be the same to ensure correct alignment.
5. Spin the wheel and look for wobbling of the sprocket which would indicate poor alignment.

Sportster drive chain adjustment



1. Rear axle nut
2. Adjusting stud lock nut
3. Adjusting stud nut
4. Adjusting stud
5. Anchor bolt (1973)

6. The chain should have ½ in. of play midway between the mainshaft and the rear wheel sprocket.
7. Secure the axle nut and adjusting stud locknut. Adjust the brake rod if necessary.

GLIDE MODELS

1972 and Earlier

1. Remove the axle nut and washer from right-side and loosen the brake sleeve nut, brake anchor stud nut (left-side), and adjusting screw locknuts.
2. Proceed as described in the "Sportster" section.

Glide models rear chain adjustment (1972 and earlier)

1. Brake sleeve nut
2. Wheel adjusting screw locknut
3. Wheel adjusting screw
4. Brake anchor stud nut

1973 and Later

1. Remove cotter pin and loosen brake anchor cable nut. Loosen axle nut.
2. Adjust chain by turning adjusting nuts. Turn adjusting nuts an equal number of turns to keep wheel in alignment. To move axle forward it may be necessary to tap lightly on the ends of studs.
3. Tighten axle nuts and brake anchor cable nut, replace cotter pin. Check chain adjustment.

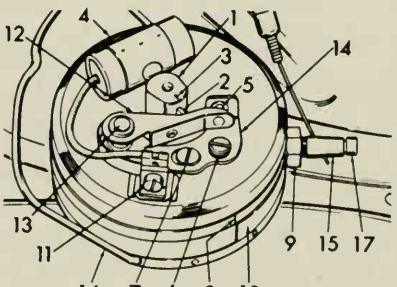
TUNE-UP



NOTE: *Common tune-up procedures are explained in detail in "General Information."*

CONTACT BREAKER POINTS

There are four types of contact breakers in use on all Harley-Davidson V-Twins. The points should be checked for gap and surface condition at the first 500 and 1,000 miles, and every 2,000 miles thereafter.

Single Contact Breaker with Manual Advance

This system has one pair of points which regulate the spark in both cylinders simultaneously. The narrow lobe of the cam times the front cylinder and the wide lobe times the rear cylinder. Both cylinders operate from a single ignition coil which fires both spark plugs, but at different stages of the combustion cycle. If the front cylinder is firing, the rear is dormant, since no combustible mixture is present during the exhaust stroke. Manual rotation of the circuit breaker base provides advanced or retarded timing.

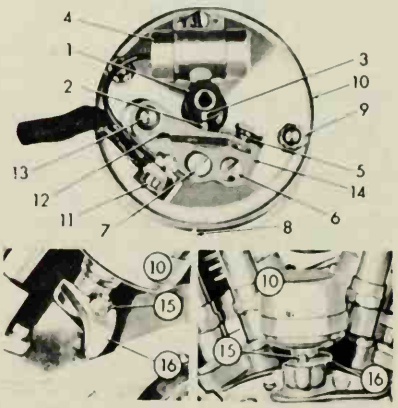
11. Wire stud screw
12. Circuit breaker lever
13. Pivot stud
14. Contact point and support
15. Timing adjusting stud
16. Cover retainer
17. Control wire lockscrew

ADJUSTMENT

1. Turn the engine over until the points are fully open to their widest gap. Loosen the point lock screw.

2. Rotate the eccentric adjusting screw until the points open far enough to insert a feeler gauge of 0.020 in.

3. Secure the lockscrew and check gap against any movement which may have occurred when securing the screw.



Single Contact Breaker with Automatic Advance

(GLIDE MODELS TO 1969 SPORTSTER MODELS TO 1970

This type of contact breaker works the same way as the manual advance type, except that the spark is automatically advanced through the action of flyweights in the contact breaker base as the engine speed increases.

Adjustment

The points on the automatic advance type are set in the same manner as on the manual advance type.

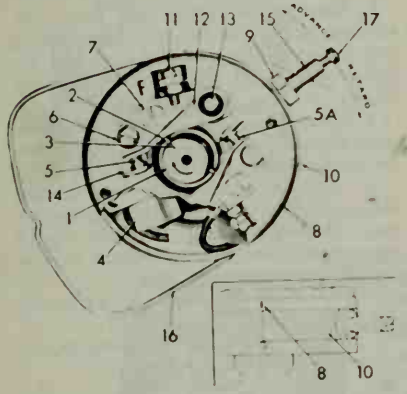
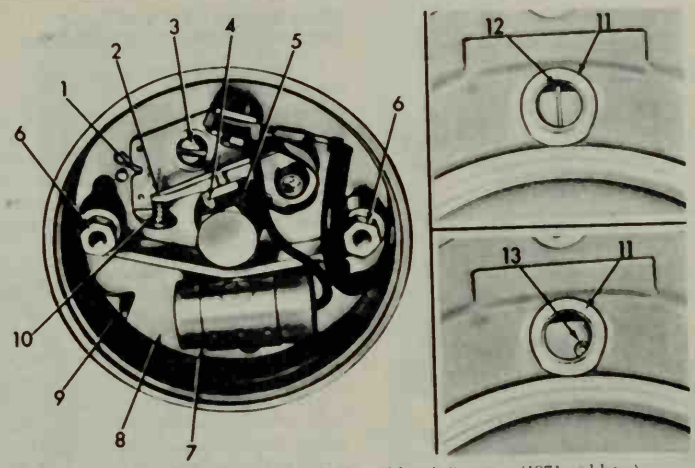
Double Contact Breaker



This system has individual contact point sets and coils for each cylinder. The single lobe cam on the timer shaft has a single mark which aligns with the fiber cam follower for each set of points when the points are open to their fullest travel. Therefore, the cam opens each set of points once every crankshaft rotation.

ADJUSTMENT

1. Loosen the front cylinder (indicated by an "F" on the breaker base) breaker point lock screw.



2. Set the front points to 0.022 in. by manipulating the eccentric adjusting screw until the proper gap is obtained. Check the gap with a wire feeler gauge. There should be a slight drag on the gauge when removing it.

3. Secure the lock screw and check gap against possible movement caused by securing the lock screw.

4. Follow the above procedure on the rear set of points.

5. Check ignition timing any time the rear set of points are adjusted as this will affect the timing. Consult "Ignition Timing" section for procedures.

Single Contact Breaker with Automatic Advance

GLIDE MODELS 1970 AND LATER SPORTSTER MODELS 1971 AND LATER

This type of circuit breaker is the same as the "Single Contact Breaker With Automatic Advance." If, during point gap setting procedures, a discrepancy of 0.004 in. or more is discovered, the breaker cam must be checked for eccentric travel.

Adjustment

1. Turn the engine over until the points are open to their widest gap. Loosen the point lock screw.

2. Use a small screwdriver at the pry point (adjusting notch) until a gap of 0.018 in. is obtained.

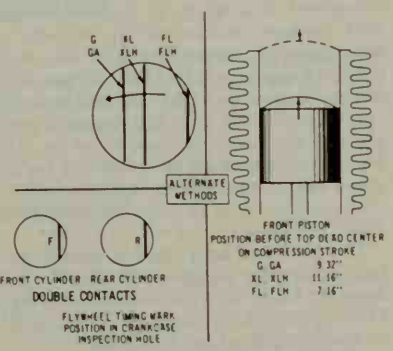
3. Secure the lockscrew and check for movement caused by securing the lock screw.

IGNITION TIMING

1. Timing should not be checked until breaker points are cleaned and properly gapped.

2. Static and dynamic (strobe light) timing are both possible. If the static method is used, support the rear wheel off the ground, remove the plugs, engage the transmission, and turn the wheel to rotate the engine. Always rotate the engine in the normal direction of rotation.

3. Telescoping the front pushrod cover will allow valve motion to be observed for static timing. The piston comes up for the compression (ignition) stroke just after the intake valve closes.



4. For dynamic timing, crankcase view plug No. 96295-65 is available to prevent oil spray.

Static Timing

MANUAL ADVANCE

1. Remove the inspection hole cap from the left side of the crankcase. Telescope the front pushrod cover. Remove point cover.

2. Turn the engine in the normal direction of rotation until the front intake valves closes. Turn the engine very slowly from this point on until the timing mark for the front cylinder is aligned in the inspection hole as illustrated.

Timing marks for all models with manual timing advance

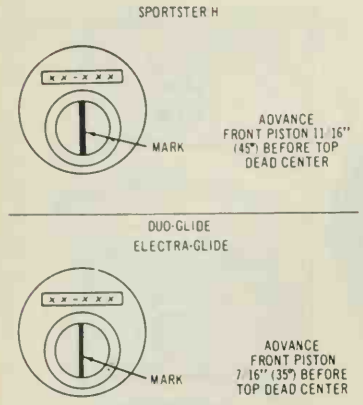
3. Check that the timing mark on the breaker point base aligns with the end of the timing adjusting plate.

4. Rotate the breaker point head counterclockwise until it reaches its stop (full advance position).

5. At this point the timing mark on the breaker cam should align with the fiber heel of the breaker points. If it does not, loosen the timing adjusting stud locknut and move the head until alignment is achieved.

Procede with the timing procedure accordingly:

6. On single contact breaker models, hook up the timing lamp. With the points in the fully advanced position, and flywheel marks correctly aligned as illustrated earlier, the points should just begin to open as indicated by the reaction of the test light. If they do not, loosen the adjusting stud locknut and move the base until the light reacts with the timing marks properly positioned. Tighten locknut and retard the timing; then advance it and check that the points open. Rotate the engine one full revolution and check that the points open at the proper time.



7. On double contact breaker models, connect the test lamp to the point wire for the front cylinder (yellow). Align the front cylinder timing mark ("F") as shown. Check test light reaction (fully advanced) as for the single contact breaker (Step 6). Repeat the procedure with the other set of points. If the rear cylinder points to not open at the correct time, adjust by changing the point gap rather than moving the base.

AUTOMATIC ADVANCE

NOTE: *Static timing is not recommended since it will result in timing being slightly retarded. On automatic advance models, a strobe light should be used.*

Glide Models to 1969 Sportster Models to 1970

1. Remove the plug from the inspection hole on the left of the crankcase. Telescope the front pushrod cover and remove the breaker point cover.

Timing marks for all models with automatic timing advance

2. Turn the engine in the normal direction of rotation until the front cylinder intake valve closes, then continue turning slowly until the flywheel advance timing mark is aligned in the very center of the inspection hole.

3. The cam must be turned clockwise as far as possible (full advance position) and held there while checking the timing.

4. At this point, the timing mark on the top of the cam should align with the breaker point fiber heel. If it does not, shift the breaker head so that alignment is obtained:

a. A limited adjustment is available on 1965 models due to slotted holes in the timer plate in which the base studs ride. Loosen the contact breaker head nuts and shift the base by prying between the plate lip and the base stud with a screwdriver.

b. If this is not enough, the entire shaft must be loosened, lifted free, and rotated a couple of teeth until the follower and the cam mark are in alignment. This will cause the base timing marks to go out of alignment.

c. When the cam and fiber align, while in the fully advanced position, secure the timer plate nuts. Overtightening will cause distortion of the timer base plate and affect timing.

d. On 1966 and later models there is a clamp on the contact breaker stem to allow a 360° adjustment range. Loosen the clamp bolts and turn the head clockwise to retard or counterclockwise to advance the timing to attain alignment.

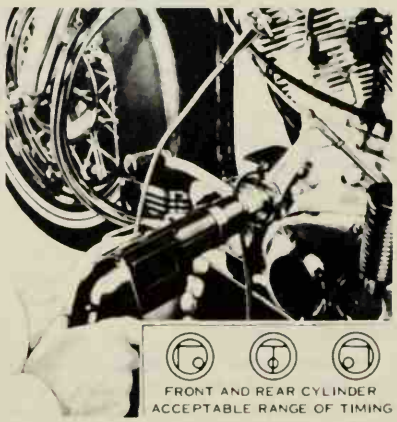
5. The cam must be turned clockwise as far as possible when checking alignment as noted previously. This is the full advance position.

6. Hook up the test light. The points must begin to open just as the advanced flywheel mark is aligned in the center of the inspection hole. If adjustment is necessary, loosen the nut or bolts and rotate the breaker point head so that the light reacts just as the flywheel advanced mark is in the center of the inspection hole. Be sure the cam is held in the full advance position as this is checked.

Glide Models 1970 and Later
Sportster Models 1971 and Later

1. The procedure is essentially the same as for earlier models except that there is no preliminary cam mark alignment necessary. The cam must be held in the full advance position when checking.

2. If timing adjustment is necessary, loosen the two breaker plate screws and rotate the plate until proper timing is achieved.



Dynamic Timing

ALL MODELS

1. Timing should be checked at about 2,000 rpm or the full advanced position.

2. At that engine speed, the strobe light, which is connected to the front cylinder, should show the timing marks centered in the inspection hole.

3. If adjustment is necessary, rotate either the breaker point head or the breaker plate, depending on model. Refer to "Static Timing" or the illustrations.

Timing with a strobe light

SPORTSTER XLCH MAGNETO

The magneto is a generating system composed of a rotor, an induction coil with primary and secondary circuits, a condenser, a contact breaker cam, and contact breaker points. High-voltage discharge is produced and directed to each spark plug twice in a 360 degree cycle, because the magnetic field must be collapsed twice so each plug will fire on its given power stroke. The magneto is shut off by a grounding circuit controlled by a "kill" button.

The 1965 and later models have a mobile mounting plate which allows the spark to be retarded for easier starting. This adjustment is made by a twist-grip on the left-side of the handlebar.

Adjusting Contact Breaker Points

1. The points should be examined for proper gap and surface 1,500 miles after installation and then at intervals of 2,000 miles.

2. Remove the carburetor, air cleaner, and magneto cover.

3. Remove the plugs and place the transmission in High gear. The engine may be rotated by setting the machine on the center stand and turning the rear wheel.

4. Rotate the engine in its normal running direction until the cam follower is on either high point of the cam.

5. Clean the points with either a point file or fine metal sandpaper before setting, and blow clean. When in doubt about point condition, it is best to replace them.

6. Check the gap with a feeler gauge. (0.015 in.).

7. Adjust the points by loosening the pivot and adjustment screws.

Setting Ignition Timing

Ignition is timed with the spark advanced and is correctly set when the forward piston is 45 degrees ($^{11}/_{16}$) in.) before top dead center. This corresponds to the flywheel timing mark position when it is in the center of the inspection hole. Whenever the points are replaced, or at least annually, the timing should be set.

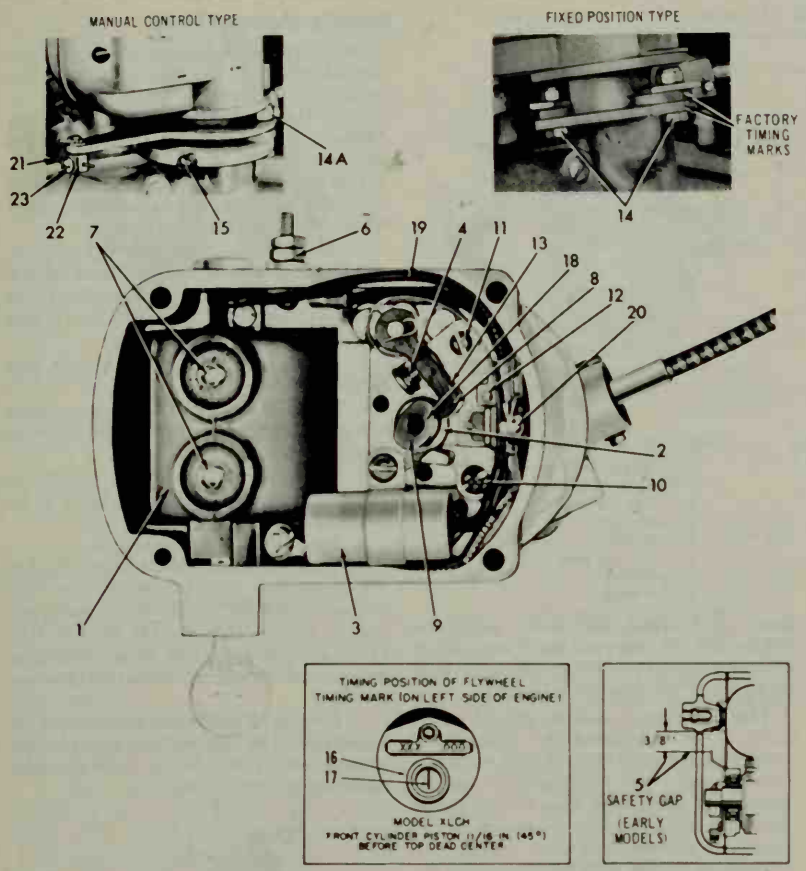
The 1965–1967 models have an adjusting screw which, when turned clockwise, advances the timing. A counterclockwise adjustment retards the timing. Applying mild pressure to the magneto housing will cause it to follow the movement of the adjusting screw. The correct amount of spark retardation is obtained by backing off the setting stop screw until there is a distance of $^{3}/_{16}$ in. between its head and seat. Adjust the screw only one turn; more will affect retarded timing.

Late 1967 XLCH models have a slot and pin in the base plate which serves the same function as the adjustment screw.

1. Remove the magneto cover, timing inspection hole plug, and spark plugs. Telescope or remove the front intake pushrod cover so that valve motion can be observed.

2. Place the transmission in High gear and put the motorcycle on its center stand so that the engine can be turned by rotating the rear wheel.

3. Set the contacts points.



4. Turn the engine until the exposed valve closes (travels to its highest point). Slowly rotate the engine in its normal running direction until the timing mark is aligned in the center of the inspection hole.

5. Align the timing marks on the magneto base and mounting plate.

6. If the narrow cam lobe is not located counterclockwise from the cam follower and the breaker points aren't beginning to open, the magneto must be adjusted. Be sure the spark is fully advanced.

7. On 1965 to early 1967 models, an adjustment can be made with the magneto advance stop screw.

8. If alignment, which will not interfere with the air cleaner, cannot be made through adjustment of the screw, or if it is a fixed-position magneto, lift up the magneto until its drive gears become unmeshed. Turn the cam the amount it was

out of position and replace the magneto. Repeat this until the proper point timing is obtained and then secure the magneto.

9. A timing or continuity light is one accurate means of determining when the points begin to open. Attach one test lead to the terminal post or point spring and the other to a ground. When the points break contact the light will go out. An emergency method is to place cellophane between the points and to tug gently on it. When the points begin to open, the cellophane will be released.

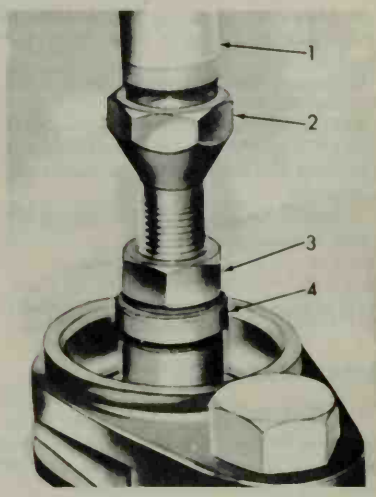
10. A strobe light provides the most accurate setting since it is done with the engine running. This takes up any end-play and automatically advances the timing. Leads are attached to the front plug, ground, and the positive battery terminal. Timing view plug, part HD (No. 96295-65), must be used to prevent oil spray. The engine should be operating at between 1,500 and 2,000 rpm.

11. Recheck ignition timing, always rotating the engine in the direction of normal operation. Never overtighten the coil lead wire as this may damage insulators and cause a short circuit.

VALVE TAPPET ADJUSTMENT

Sportster

Valve tappets must be adjusted with the engine cold. Adjust the tappets after the first 500 and 1,000 miles, and thereafter at every 2,000 miles.



1. Press down on the pushrod cover retaining spring and remove the cover spring keeper.

2. Block up the telescoped cover so it doesn't slip down.

3. Rotate the engine until the valve that is to be adjusted is at its lowest position.

4. Loosen the tappet adjusting screw locknut and turn the adjusting screw into the tappet body until the pushrod is free and will shake slightly. Hold the pushrod just below the cylinder head and shake it toward the front and rear of the engine.

5. Gently turn the adjusting screw toward the pushrod until nearly all play is removed. Secure the tappet screw locknut against the tappet body.

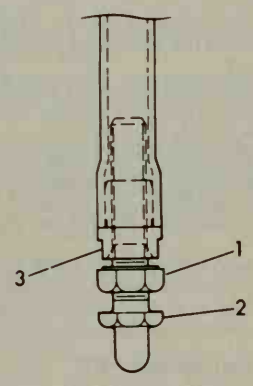
2. Tappet adjusting screw
3. Tappet adjusting screw locknut
4. Tappet body

6. Check adjustment again for a slight amount of shake and the ability to rotate freely without any rough spots or binding.

7. Both ends of the valve covers must seat on the cork washers during reassembly.

8. Perform the above operations on the remaining three valve tappets.

Glide Models



Tappet adjustment is not necessary unless the engine has been disassembled. Adjustment must be made on a cold engine.

1. Remove the pushrod cover cap spring retainers.

2. Each tappet must be adjusted when at its lowest position. This can be found by rotating the engine until the corresponding valve of the other cylinder is fully open.

3. Loosen the tappet adjusting screw locknut and turn the adjusting screw into the tappet body so that the pushrod is shortened and will shake slightly.

4. Hold the pushrod with a wrench and turn the adjusting screw down to lengthen the rod until all of the play is taken up.

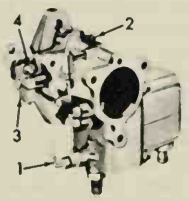
5. Mark the adjusting screw position with chalk and turn it down four full turns.

6. Secure the locknut while holding the pushrod steady.

NOTE: *Allow the hydraulic units to bleed down after adjustment before turning the engine over to adjust the next one.*

7. Install the pushrod cover spring cap retainers.

CARBURETOR ADJUSTMENTS



Linkert Model "DC"

1. Check the cable adjustment to be sure that the throttle opens and closes fully. Run the engine until the normal operating temperature is reached.

2. Turn the low- and high-speed needles gently to their seat, and back the low-speed needle out 1½ turns so that the engine will start. You may wish to turn the idle stop screw clockwise to raise the idle speed slightly.

3. With the choke in the fully opened position and the spark fully advanced, turn low-speed needle in slowly until the engine misses and runs irregularly. Turn the needle out counterclockwise until the engine runs smoothly with the throttle closed. A slightly richer mixture, obtained by turning the needle in, will aid starting and overall performance.

4. Adjust the throttle stop screw until 700–900 rpm idle speed is obtained.

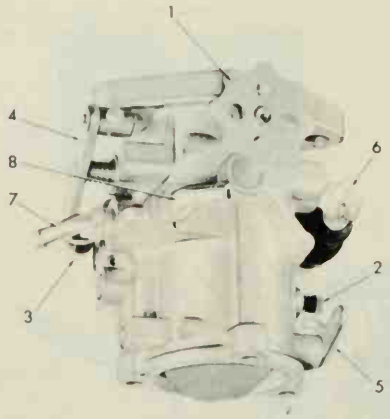
2. Low-speed needle
3. Throttle lever
4. Throttle stop screw



5. After adjusting the idle, slight readjustment of the low-speed needle may be required.

6. Turn the high-speed needle ¾–1¼ turns off its seat and run the machine at various speeds from 20 mph up, with the spark fully advanced. If the engine runs roughly, make small adjustments until you are satisfied. There should be uniform smoothness throughout the speed range.

7. Once a proper setting is arrived at, further readjustment should require no more than ⅛ turn of the low-speed needle and ¼ turn of the high-speed needle.

lines, and check for leaks (with the engine hot) by dripping small amounts of oil on the seams and by watching for bubbling when the engine is started.

The low-speed needle should never have to be readjusted for atmospheric variations by more than ⅛ turn, richer or leaner, and the intermediate needle should not need more than ¼ turn richer or leaner because the fuel supply is decreased; counterclockwise makes the engine run richer. Idle is adjusted by the idle stop screw.

If atmosphere, altitude, or modifications to the engine or exhaust system renders adjustment ineffectual, the following main jets may be substituted: 0.049, 0.051, 0.053 (Electra-Glide standard jet), 0.055, 0.057, (Sportster standard jet), 0.059, 0.061, or 0.063.

1. Loosen the cable adjustment so that the throttle lever will open and close fully in response to handlebar manipulation.

2. Turn both the low and intermediate-speed needles in to their seats and then back out about ⅞ turn. This adjustment will allow the engine to start but will cause it to run too richly.

3. When the engine reaches normal operating temperature, open the choke all the way and fully advance the spark.

4. Set the throttle stop screw so the engine idles at about 2,000 rpm.

5. Turn the intermediate needle in both directions until the engine runs at its smoothest, with no surge, and with a constant rpm pulse. When the optimal setting is achieved, back the needle out ⅛ turn so the mixture is slightly rich.

6. Adjust the idle stop screw so the engine runs at about 900–1,000 rpm.

7. Adjust the idle needle in the same manner as the intermediate needle.

8. Recheck both needle adjustments.

The idle mixture is made richer by turning the adjusting screw to the right and is made leaner by turning it to the left. The main nozzle provides a richer mixture when the screw is turned to left and leaner when turned to the right.

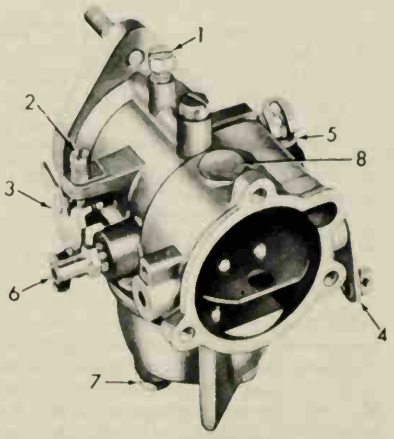
Bendix Model 16P12

Once properly adjusted, major changes should not be necessary. Check for fouled or bad plugs, improper timing, poor valve adjustment, clogged air cleaner, or air leaks at the manifold or gas line.

The low-speed needle is turned clockwise for a leaner mixture or counterclockwise for a richer mixture.

1. Gently turn the low-speed mixture needle clockwise to its seat, then back it out 1½ turns (1972–73) or 2¼ turns (1974 and later). The engine should start at this setting but will run too richly.

2. Make sure the cable allows the throttle to close fully.



3. With the engine at normal operating temperature, set the throttle stop screw to 700–900 rpm.

4. Readjust the low-speed needle to the point where the engine runs at its smoothest and at its highest rpm.

5. Reset idle to 700–900 rpm.

6. If the exhaust system is modified or if the machine is to be operated at high altitudes, one of the following main jets may be substituted: nos. 90, 95, 100, 105, 110, 115, 120, and 125. When changing jets, go up one size at a time until you are satisfied.

7. Late 1971 and later pump shafts are adjustable. The bottom hole provides the richest setting and the top hole provides the leanest.

Keihin

1. Turn the low speed mixture screw in gently until it is seated, then back it out 1½ turns.

2. Adjust the throttle stop screw to allow engine idle at desired speed. This should be 700–900 rpm.

3. Adjust the low speed mixture screw (on warm engine) turning it in and out so that the highest or smoothest idle is obtained.

the mixture. The screw will probably have to be turned in slightly from the 1½ turn position.

4. Readjust the throttle stop screw, if necessary, so that idle speed is 700–900 rpm.

5. The carburetor is fitted with an accelerator pump. The pump has an adjustable screw which controls the amount of fuel injected. Standard setting for this screw gives a distance of about ¼ in. (6 mm) between the stop and the end of the screw. Increase fuel by turning the screw out. Decrease by turning the screw in.

6. The pump rocker arm spring controls duration and has three possible positions on the rocker arm. The center notch is the standard position.

7. The main jet may be changed for high altitude. Standard main jet size is 185 meaning the the jet will pass 185cc of fuel per minute. Alternate jets are available from 160 to 185 in steps of 5cc.

ENGINE AND TRANSMISSION

ENGINE REMOVAL AND INSTALLATION

Sportster

1. Remove the seat, drain the gas and oil, and remove the gas tank. The following steps pertain to the right-side of the machine:

2. Remove the air cleaner assembly.

3. Disconnect the throttle and choke cables at the carburetor.

4. Remove the top center engine support bolt, taking note of the number and placement of the spacer shims.

5. Remove the exhaust assemblies.

6. Disconnect the spark plug cable from the contact breaker or magneto.

7. Remove the starter crank and spring.

8. Place the transmission in Fourth gear and remove the right footrest and the shifter lever (1974 and earlier). On 1975 and later machines, remove the right footrest and brake lever.

9. Remove the transmission sprocket cover. Disconnect the clutch cable. On 1975 and later machines, detach the shifter link from the arm of the shifter pedal cross shaft.

10. Remove the drive chain from the countershaft sprocket.

11. Remove the oil return line.

12. Remove the oil vent and oil feed lines. Remove the breather pipe.

13. Remove the clutch cable and oil pressure switch.

14. Disconnect the speedometer cable. Remove the lower front safety guard bolt. The following steps pertain to the left-side of the machine:

15. Loosen, but do not remove, the top front engine mounting bolt.

16. Remove the remaining three, front engine mounting bolts.

17. Remove the tool box (1966 and earlier XLH).

18. Remove the battery tie rod support (1966 and earlier XLH).

19. Disconnect the battery ground wire and the spark plug cables.

20. Remove the horn and engine support bracket.

21. Disconnect the throttle cable and support bracket at the carburetor.

22. Remove the battery cover and disconnect both terminal leads on XLH models.

23. Remove the oil vent line at the crankcase (1966 and earlier models).

24. Disconnect the contact breaker-to-coil lead.

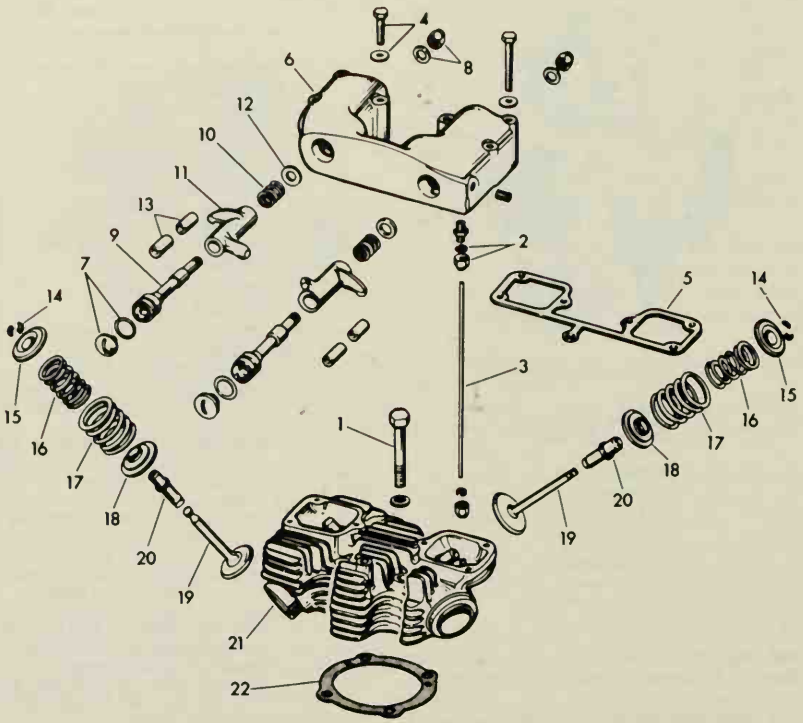
25. Remove the battery, battery carrier, and oil tank.

26. Remove the regulator ground strap and the two, top rear, engine mounting bolts.

27. Remove the rear brake lever and return spring on 1974 and earlier models or the gearshift foot lever on 1975 and later models, and the stop switch on 1966 and earlier models.

28. Remove the left footrest.

29. Remove the two, lower rear, engine mounting bolts.



30. Remove the top front engine mounting bolt.

31. With the engine tilted forward, lift it up and out of the left side of the frame.

Glide Models

For cylinder work with the engine still in the frame, complete the following steps:

1. Remove the instrument cover mounting base screw and pry off the cover side plate.
2. Remove the seat.
3. Remove the shift lever bottom bolts to remove the gas tank on hand-shift models.
4. Drain the gas tank and remove it.
5. Remove the cylinder head bracket, taking note of the number and position of the spacers for reassembly.
6. Remove the spark plugs and disconnect the battery ground wire.
7. Remove the carburetor manifold clamps and the air cleaner assembly.
8. Disconnect the throttle and choke cables from the carburetor, then remove the fuel and vent lines, carburetor, and its support bracket.
9. Disconnect the exhaust pipes at the cylinders. Disconnect and reposition the regulator without removing it. Follow the steps below to remove the engine crankcase from the frame:
10. Remove the left footrest, primary chaincase cover, compensating sprocket, or shaft nut. Remove the chain adjuster mounting bolt and clutch assembly.
11. Remove the engine sprocket shaft chain cover. Loosen the transmission base mounting bolts. Remove the inner chainguard-to-transmission mounting bolts.
12. Remove the clutch hub, shaft key, starter housing chainguard nuts, solenoid wire, inner chainguard from mainshaft, chain oiler hose at oil pump, and the remaining hoses.
13. Disconnect the coil leads, generator wires, and oil switch wire.
14. Drain the oil tank and remove the oil lines at the oil pump. Remove the crankcase breather tube.
15. Remove the right footrest and the brake master cylinder assembly.
16. Remove the exhaust system.
17. Remove the front and rear engine mounting bolts. The engine may now be lifted clear of the frame through the right side.

CYLINDER HEAD AND VALVES

Sportster

REMOVAL

1. Strip the motorcycle as described in "Engine Removal" following Steps 1–6, 20, 21, and 24.
2. Remove the air cleaner assembly, carburetor support bracket, carburetor, manifold clamps, and manifold.
3. Remove the oil line nuts and rubber sleeves.
4. Remove the spark plugs.
5. Remove the pushrod cover spring keepers while holding the spring retainers down.
6. Telescope the valve covers.
7. Rotate the engine until there is clearance at both tappets. The valves are now closed.
8. Remove the cylinder head bolts and washers.
9. If necessary gently tap the base of the head with a soft mallet to loosen it and lift the entire assembly free through the left side of the frame. Lightly oil the piston crown and cylinder.
10. Separate the pushrods and mark them for replacement in their original positions.

DISASSEMBLY

1. Remove the rocker arm cover bolts and washers.
2. Remove the rocker arm cover, tapping it gently with a soft mallet to loosen it if necessary.
3. Inspect the rocker arm surfaces, for excessive wear, where they contact the valve stems and pushrods.
4. Check the rocker arm shaft and bushing for excessive play.
5. If replacement of the above items is necessary, remove the rocker arm shaft, O-ring, acorn nut, and washer.
6. Drift the shaft from the cover and remove the rocker arm spring, arm, and spacer, and separate them for replacement in their original positions. It is not a good idea to mix parts since this will affect clearances and since some parts are not interchangeable.

CAUTION: *Intake and exhaust rocker arms are not interchangeable.*

7. Compress the valve springs using Valve Spring Compressor (H-D Part No. 96600-36), or any suitable spring compressor and remove the valve keys spring collar, springs, and valves. Separate the parts for replacement in their original positions.

INSPECTION

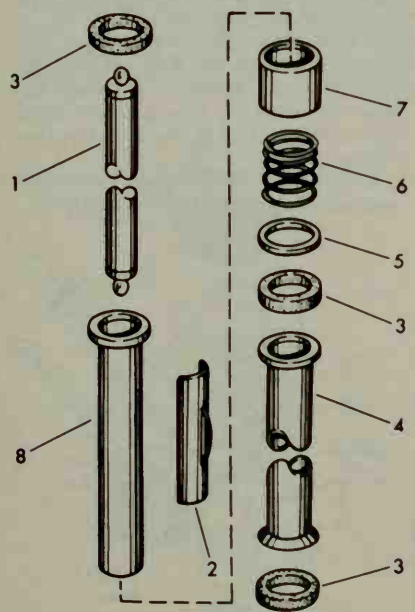
1. Clean all parts in a suitable solution and blow them dry, taking care to blow all passages clear.
2. Replace the oil line nut rubber sleeve and the gaskets if worn. Replace the shaft O-ring.
3. Inspect the rocker arm and shaft for wear and replace them if necessary. Rocker arm pads may be ground free of pitting or uneven wear.
4. Replace shaft bushings if play exceeds 0.002 in. Bushings are a press-fit and must be drifted out from the acorn nut side. Inserting a ⅜–11 thread tap will aid in the drifting procedure. Line-ream the new bushing with Reamer (H-D Part No. 94804-57) or a suitable substitute.
5. Soak the head in a suitable solvent until all of the carbon deposits are soft, then gently scrape it clean and brush it with a wire brush, taking care not to scratch the head face.

6. Blow the cylinder head and passages clear and clean again in a suitable solvent.

7. Inspect the valve and valve seat for a pitted or corroded condition which may adversely affect seating. Consult "Valve and Valve Seat Refacing" for procedures or replace. Seats which are cracked or loose must be replaced as described in "Valve Seat Insert Replacement."

8. Remove the valve head and the stem carbon deposits with a wire wheel or blunt knife, taking care not to scratch or nick the surface. The stem may be polished with fine emery cloth or steel wool. Warped, bent, or otherwise damaged valves must be replaced.

9. Intake valve guides may be cleaned up with a 5/16 in. reamer and the exhaust valves with a 11/32 in. reamer.



10. Inspect the guides for excessive stem clearance. Consult "Engine Specifications" for proper measurements.

11. Replace the pushrods if warped, bent, or flattened at the ball ends.

12. Inspect the valve springs and check for proper tension and length. Springs which are more than 1/8 in. shorter or which have 5 lbs less tension than listed in "Engine Specifications" must be replaced. A Valve Spring Tester (H-D Part No. 96797-47), or a suitable substitute, may be used. If the springs are still their original length, they may be used even if their strength isn't checked.

PUSHROD REMOVAL AND INSTALLATION

1. Rotate the engine until the tappet is at its lowest position.

2. Turn up the adjusting screw locknut until it is seated against the adjusting screw.

3. Turn down the adjusting screw, into the tappet body, until it reaches its seat.

4. Pry the pushrod up and to the side, taking care not to bind the upper end in the rocker housing, and remove the rod and cover assembly.

5. Install new cork cover washers in the rocker cover and tappet guide, taking care not to damage them. Install a new cork washer in the pushrod cover also, taking care to seat all washers.

6. Assemble the pushrod assembly in the reverse order of disassembly and adjust tappets as described in "Valve Tappet Adjustment."

ASSEMBLY

Assemble in reverse order of disassembly. Note the following:

1. Lightly oil the valve seats and stems.

2. Place the lower valve spring collar over the guides, taking care to seat it properly.

3. Install the springs and upper collars, and use a compressor to replace the valve keys. Keys are easily handled by placing a dab of grease on a screwdriver tip, and can be temporarily secured until the springs are released by greasing the key grooves.

4. Install the rocker arm spacer, spring, and arm.

5. Lightly oil the rocker arm shaft and install it so that the spring ends are flush with the spacer and arm.

6. Secure the shaft O-ring, shaft screw, acorn nut washer, and acorn nut. Check arm action for binding.

7. Check to see that the cylinder head and rocker arm surfaces are still clean and apply a thin coat of aluminum paint to the head face if a cover gasket is not to be used.

8. Carefully install the cover gasket, if applicable, and install the cover in either case.

9. Turn the screws to a snug fit and then turn each 1/8–1/4 turn at a time until the cover is secure.

INSTALLATION

Install in the reverse order of disassembly. Note the following:

1. Cylinder and head faces must be absolutely clean.

2. Lightly oil or grease both sides of a new head gasket and align it on the cylinder.

3. With the valve tappets in their lowest position, install the head assembly. Pushrods must seat in the tappet screw and pushrod sockets.

4. Insert the oil line in the head and crankcase fittings.

5. Secure the cylinder bolts in the same manner as the rocker cover bolts and torque them to 65 ft lbs.

6. Position the rubber, oil line nut sleeves and secure the nuts.

7. Install the intake manifold and replace the rubber O-rings before installing the carburetor. Correct alignment of these units is critical as air leaks adversely affect performance. The cylinder may have to be shifted slightly to provide proper manifold alignment.

8. Adjust the tappets as described in "Valve Tappet Adjustment."

9. Assemble the remaining parts in the reverse order of disassembly.

Glide Models

REMOVAL

1. Refer to Steps 1–9 under "Engine Removal and Installation."

2. Remove the carburetor and manifold.

3. Disconnect the cylinder head oil lines.

4. Remove the spring cap retainers on the pushrod covers. Remove the head bolts. Lift the cylinder head and remove the pushrods and covers. Remove the head.

5. Mark the pushrod locations for reassembly.

DISASSEMBLY

1. Remove the rocker arm cover.

2. Check the rocker arm pads and ball sockets for wear. Check the shaft for play. If removal is necessary, remove the rocker arm shaft screw and o-ring. Remove the acorn nut and washer. Drift the shaft from the cover and remove the rocker arm and spacer.

3. Mark all parts so that they can be assembled in their original positions.

4. Compress the valves springs with tool No. 96600-36 or a suitable substitute. Remove valve and spring assembly.

INSPECTION

1. Consult Sportster "Cylinder Head Inspection."

2. Bearing faces, with dowel pins removed, may be sanded with emery cloth to reduce clearances. A suitable reamer (such as Reamer HD Part No. 94804-57) may be used to line-ream the bearing.

3. Gently strike the edges of the bearings, while assembled, to align parts before the checking fit.

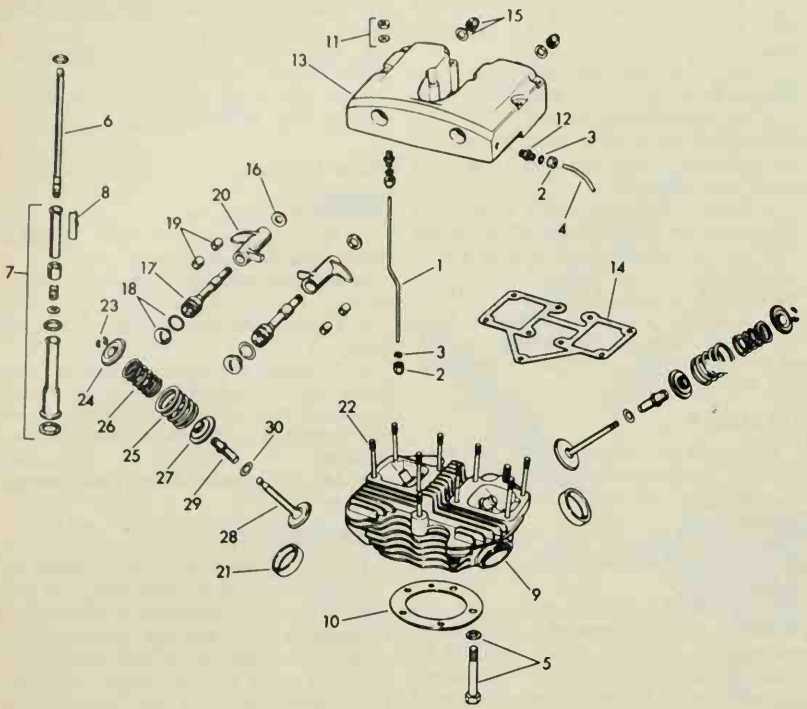
4. Continually sand, clean, check clearances, and repeat until the desired fit is obtained.

ASSEMBLY AND INSTALLATION

Assemble in reverse order of disassembly. Note the following:

1. Assemble the valve assemblies as described in Sportster "Cylinder Head Assembly."

2. If the rocker arm is not free, the lifters will not fill with oil.



3. Replace rocker arm cover using aluminum paint on the cover faces, unless the model is equipped with a gasket as on 1971 and later models.

4. Raise the valve end with a screwdriver when the cover is installed to prevent rocker arm jamming on 1966 and later models.

5. See Sportster "Cylinder Head Installation" for torquing and carburetor assembly procedures.

6. Adjust the tappets as described in "Valve Tappet Adjustment."

7. Assemble remaining parts in reverse order of disassembly.

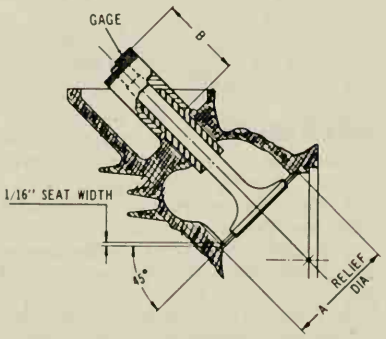
Valve Guides and Seats

REPLACEMENT VALVE GUIDES

Sportster

1. Valve guide clearance must be within 0.003–.005 in. Guides must be replaced if play exceeds 0.002 in.

2. Using a shouldered drift or an arbor press, remove the valve guides from the valve head side.



3. Carefully tap the new guide squarely into place and ream it with a suitable reamer to remove any possible high spots.

4. Ream the guides, with a 5/16 in. reamer for the exhaust guides, and a 11/32 in. reamer for the intake guides, to assure a smooth and perfectly round fit. 1972 and later models require Valve Guide Reamer (H-D Part No. 94830-47) or another suitable reamer.

Glide Models

1. Same as Steps 1–3 for the Sportster.

2. Exhaust valve guide clearance must be within 0.004–0.006 in. Intake valve guide clearance must be within 0.002–0.004 in. Guides must be replaced when play exceeds 0.002 in.

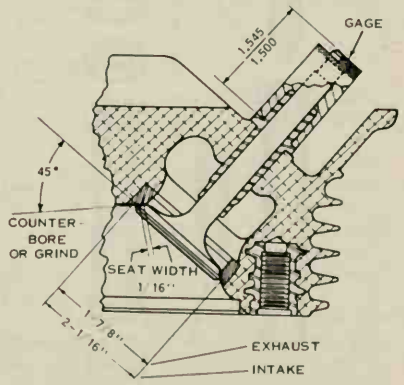
REFACING VALVES AND SEATS

1. If the valve guides are to be replaced, do so before refacing the valves and seats.



2. Use Valve Grinding Tool (H-D Part No. 96550-36) or one of the many commercial grinding tools available.

3. Grind the seat to a 45 degree angle so that the seat is 1/16 in. wide.

4. If the seat is wider than 1/16 in., it may be narrowed by grinding the valve seat relief at a 15 degree angle.

5. Grind the valve to 45 degrees and only long enough to clean and true the surface. Avoid excessive grinding. Replace the valve if it is excessively pitted or warped, or if it is sharp at the face edges.

6. The valve stem end may be finished on a grinding wheel if worn unevenly.

Glide models valve seat tolerances

LAPPING VALVES AND SEATS

1. After the valve faces and seats are ground, apply a light coat of fine lapping compound and insert the valve in the guide.

2. Rotate the valve several times with a grinding tool while applying light pressure at the face and seat by pulling on the valve stem. This may also be done by hand. A good way is to put a piece of gas line over the stem and hold the head so the stem is up. Rotate it several times and then check as described below.

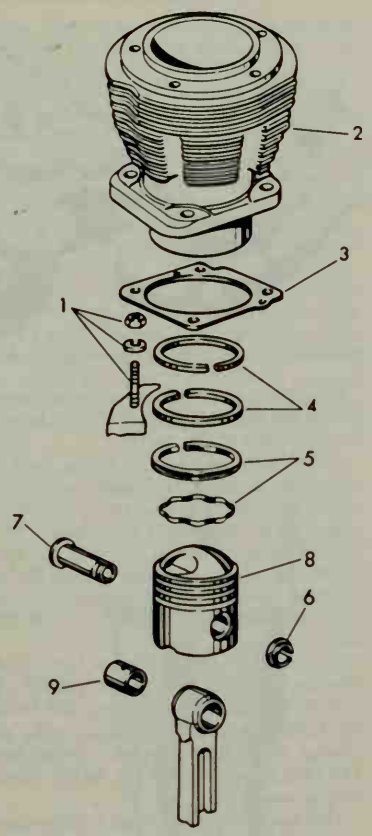
3. To check for a well-seated valve, clean the seat and face thoroughly and insert the valve. Apply light pressure to the seat and face, then pour some gasoline on the valve from the combustion chamber side. If it takes several seconds (10–15 is a good indication) before leakage occurs, lapping has been successful.

CYLINDERS AND PISTONS

All Models

DISASSEMBLY

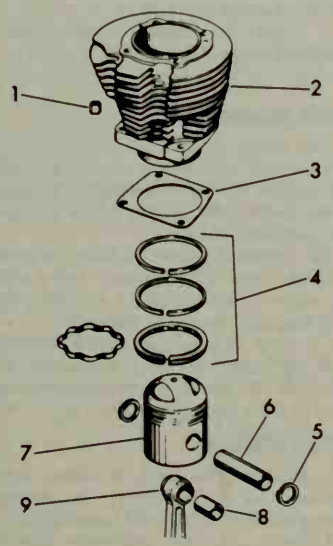
1. Remove the cylinder head as described in "Cylinder Head Removal."



2. Clean the crankcase thoroughly at the cylinder base. The front cylinder must be removed first on Glide models.

3. Remove the cylinder base nuts and raise the cylinder high enough to place a clean, oily rag over the crankcase to prevent foreign objects from falling in.

4. Rotate the engine until the piston is at its lowest point and lift the cylinder free.



5. Discard the cylinder base gasket.

6. Remove the cylinder compression rings with a ring expander. Rings can also be removed by prying one end free and blocking the other end or by pulling both ends free of the piston. If the rings will not clear the piston completely, work them off slowly, taking care not to scratch or nick the piston surface. Once removed, rings should be replaced.

9. Connecting rod

7. Pry the piston pin lock rings free and discard them. Glide models (1972 and earlier) have a lipped piston pin lock ring. Use Tool No. 96780-32A to push out the right-side ring and pry it off.

8. Push out the piston pin from the piston until it can be removed. Mark the pistons for reassembly in the original cylinders.

9. Remove the piston pin bushing, if necessary, using Piston Pin Bushing Tool (H-D Part No. 95970-32A), and Connecting Rod Clamping Tool (H-D Part No. 95952-33) or remove the connecting rod and support the rod around piston bore then drift it free. Consult "Connecting Rod Small End Bushing Replacement."

INSPECTION

1. Inspect the piston pin and pin bushing for a pitted, scored, or loose condition and replace if necessary. Pins are a hand-press fit with about 0.001 in. clearance. If the pin and pin bushing fit is more than 0.002 in. loose, replace worn parts as described.

2. On Sportsters, the front rod must have no more than $^{11}/_{64}$ in. axial or radial play and no more than $^{3}/_{64}$ in. for the rear before lower bearing replacement is indicated.

3. On Glide models, the rod bearing should be replaced when either rod has more than $^{3}/_{32}$ in. side shake at the upper end or appreciable up and down play.

CYLINDER BORE REFINISHING

1. Measure cylinder bore by taking measurements from front to rear and side to side with an inside micrometer at both ½ in. from the top of the cylinder. Repeat at the bottom of ring travel to determine cylinder roundness.

2. Measure piston diameter perpendicular to the wrist pin at the base of the piston skirt to check for roundness.

3. Subtract the piston diameter from the cylinder bore to arrive at a clearance measurement.

4. Refinishing is necessary if the cylinders are scuffed, scored, or worn greater than 0.002 in.

5. Oversize pistons should be fitted when cylinder wear is greater than 0.002 in.

6. If wear exceeds 0.002 in., the cylinders must be bored to the next standard oversize and fitted with suitable pistons and rings.

7. Oversized pistons and rings are available in 0.005, 0.010, 0.020, 0.030, 0.040, 0.050, 0.060, and 0.070 in. oversizes.

8. When it becomes necessary to exceed the 0.070 in. oversize, new cylinders are required.

9. New pistons of the same original size may be used if the cylinders are not worn in excess of 0.002 in. if damage does not make boring necessary, and total piston clearance is 0.002–0.006 in. Replace the rings and rough up the cylinder walls with no. 150 carborundum emery cloth.

10. Refinish the cylinders with a hone or boring bar, and then with a finishing hone. If the cylinders are not badly scored or worn, a hone alone should suffice.

11. Bore to slightly less than the nearest oversize if badly worn or scored, and then finish with a hone to the exact size.

PISTON RING ASSEMBLY

1. Replace the rings even if the same pistons are to be used.

2. Rough up the cylinder walls with carborundum emery cloth to facilitate ring seating.

3. The top two ring grooves are for the compression rings. The lowest groove is for the oil control ring.

4. Consult "Engine Specifications" for ring and piston fit and gap specifications.

5. Ring gap is determined with the piston crown ½ in. from the top of the cylinder. Lay the ring to be checked on top of the piston and check the gap with a feeler gauge.

6. Use standard size pistons and rings in standard bores or match oversize rings and pistons in oversized bores. Oversized rings are available in 0.010 in. gradations from 0.010–0.070 in. Regardless of the oversize, the proper gap is the stan-

dard gap. A smaller gap may cause ring failure. If necessary, increase gap with a fine-cut file.

7. Using a ring expander, slip the oil ring in place and then the two compression rings. Rings are fit with the chamfered or dotted side up. Later models may have one side of the ring marked "TOP" which must face upwards when the ring is installed.

8. Stagger ring gaps 120° before assembling the piston in the cylinder.

CONNECTING ROD SMALL END BUSHING REPLACEMENT

1. Bushings are a hand-press fit and must be tight in the rod.

2. If the pin clearance exceeds 0.002 in., there are two possible methods of correction:

a. Ream the bushing oversize and use an oversize pin. This involves reaming the piston holes as well.

b. Install a new bushing and ream it to fit a standard pin. This is the preferred method.

3. Remove bushings by either of the following methods:

a. Remove the rod and support it around the bushing bore then drift the bushing fee.

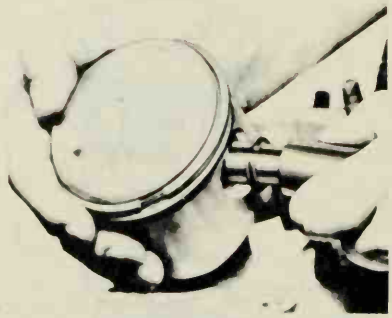
b. Assemble Piston Pin Bushing Tool (H-D Part No. 95970–32) and Connecting Rod Clamping Fixture (H-D Part No. 95952-33), and drive the bushing free.

4. Replace the bushings with the oil slot aligned with the rod oil slot.

5. Using Reamer (H-D Part No. 94800-26) or a suitable replacement, ream the bushing to size, or ream it nearly to size and finish with a hone. This is the preferred method.

6. The bushing should now afford 0.001 in. pin clearance: a slight shake when the pin is in the bushing.

ASSEMBLY



Assemble in reverse order of disassembly. Note the following:

1. Rings should be replaced if they have been removed. Gaps must be staggered 120° around the piston. Fit with the chamfered or dotted or "TOP" side up.

2. Glide models: Install the pistons so that the piston boss web is to the right-side of the engine or in the original position. The web is a small ridge underneath the piston.

Piston web is installed on the right of the engine

Installing lockring (1972 and earlier Glide models)

Sportster: The relief on the piston crown for the intake valve must face in the direction of the valve.

3. On 1972 and earlier Glide models, install the locking ring on the end of the piston pin that is not slotted. Preheat the piston in boiling water and starting from the left-side, drive the pin into position. When the pin is in place, install the remaining lockring on the piston pin using the special tool (H-D Part No. 96780-32A).

On Sportster and 1973 and later Glide models, position the piston pin in the connecting rod (thru piston) and install the lockring on the piston pin using the special tool (H-D Part No. 96780-58A) (On 1972 Sportster Part No. 96781-72 tool plug is used).

The use of new lockrings is necessary.

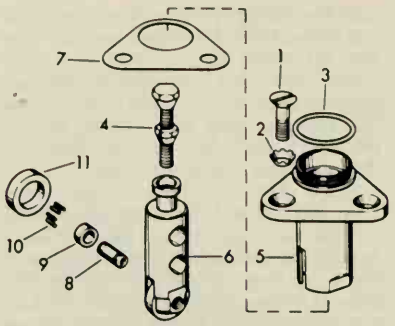
4. Lubricate the cylinder walls, pistons, pins, and bushings.

5. Assemble the cylinder using a ring compressing device if so desired.

Installing lockring (Sportster and 1973 and later Glide models)

VALVE TAPPETS AND TAPPET GUIDE

Sportster



REMOVAL

1. Remove the tappet guide screw and tappet adjusting screw.

2. Remove the tappet guide with Tappet Guide Puller (H-D 95724-57) or a suitable gear puller. Cam gears must be in place during this operation or damage to the camshaft bushings will result.

3. Remove the tappet guide O-ring, tappet body, and the tappet and roller assembly.

4. Mark the tappet assemblies for reassembly in their correct locations.

6. Tappet
7. Tappet guide gasket
8. Roller pin
9. Roller race
10. Needle rollers (25 small or 20 large)
11. Roller

INSTALLATION

Assemble in reverse order of disassembly. Note the following:

1. Lightly lubricate the tappet assembly with engine oil before assembly.

2. The roller must seat correctly on the cam and in the guide.

3. Block up the tappet, at its limit of travel, to keep it from falling into the crankcase during installation.

4. Place the O-ring and guide gasket on the guide.

5. Turn the adjusting screw and nut into the tappet and insert the tappet in the guide.

6. With the guide screw holes aligned, insert the guide into the crankcase and tap gently with a soft mallet until the guide is seated.

7. Secure the assembly and recheck for free tappet movement.

8. Adjust the tappets as described in "Valve Tappet Adjustment."

Glide Models

The Glide models have hydraulic tappets which operate under compression force from the valve springs. The tappet roller follows the surface of the cam as do the mechanical units.

The hydraulic unit contains a piston, cylinder, and a ball check valve which maintains a self-adjusting, no-play condition through the valve train.

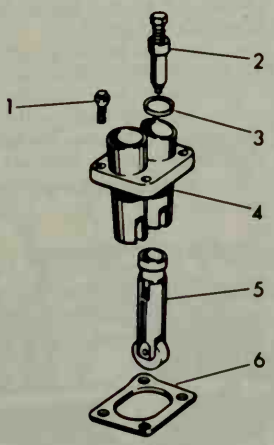
Clicking noises are to be expected until normal operating temperature is reached. A correctly functioning unit should then become quiet.

DISASSEMBLY

1. Remove the pushrod cover spring cap retainer and telescope the covers if the cylinder head is still assembled.

2. Back off the pushrod adjusting screw until the rod can be lifted free of the ball socket.

3. Remove the tappet guide screws and hydraulic units.



4. Gently tap the guides with a soft mallet to loosen them. The tappets and

guides can be removed together by pressing the tappet tops against the guide sides with thumb and forefinger, and then by lifting them clear. Do not allow the tappets to fall into the gearcase through the tappet guide mounting holes.

5. Remove the pushrod cork washers from the guides.

6. Remove the tappet from the bottom of the guide.

7. Remove the guide gasket.

INSPECTION

1. Clean all parts except the gaskets and hydraulic units in a suitable solvent and blow dry. Do not mix parts.

2. Remove the hydraulic piston and spring from the cylinder, wash them in a suitable solution, and blow them dry.

3. Clear all of the oil passages with compressed air or a piece of wire.

4. Inspect all parts for a worn or damaged condition and replace where necessary.

5. Inspect the cam condition through the gearcase guide ports.

6. Replace the entire tappet as a rule, but roller assemblies only may be replaced, if necessary, by drilling or pressing out the roller pin and installing a roller replacement kit. Rollers should have 0.0005–0.001 in. play on the bearings and about 0.008 in. sideplay.

7. Replace worn parts if the tappet fit in the guide exceeds 0.001 in.

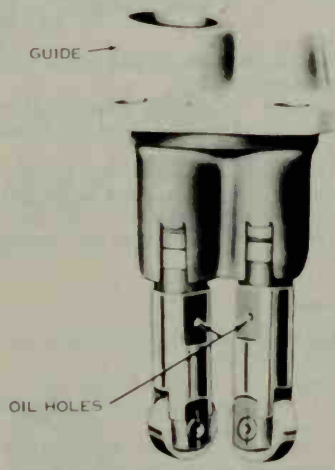
8. The guide is press-fit into the crankcase and must be replaced if play exceeds 0.0005–0.001 in.

9. If the tappet adjusting screw is worn hollow due to pushrod action, it must be replaced to ensure accurate adjustment.

10. Replace the rubber O-rings and gaskets if necessary.

CHECKING PUSHROD OPERATION

1. Check to make sure that the ball valve and seat are clean and dry.



2. Insert the piston in the cylinder.

3. Holding the piston in a vertical position, press down until the spring begins to seat on the cylinder. The cylinder base hole should not be covered.

4. Maintain this pressure for six seconds and then release. The piston should bounce back.

5. If the piston fails to return, repeat Steps 3 and 4 while covering the hole. If the piston does not bounce back, replace the unit. If the piston does bounce back, the ball is not seating and the unit must be replaced.

6. Check for a clogged oil screen beneath the large cap screw near the rear tappet guide before replacing the units. If the tappet operates correctly without the screen in place, the problem was not in the hydraulic units. Consult "Gearcase Disassembly" for screen removal procedures.

Assembling tappets in guide (Glide models)

ASSEMBLY

Assemble in reverse order of disassembly. Note the following:

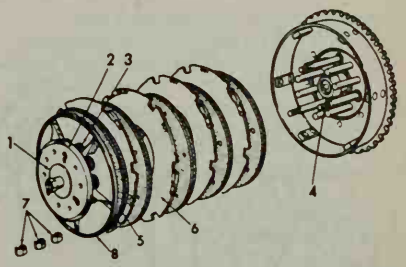
1. Insert the tappets into the guides so that the flat surfaces with oil holes are toward the center of the guide.

2. Place a dry guide gasket in position and insert the guide into the gearcase while holding the tappets with the thumb and forefinger. Secure the guide screws. Tighten to 10 ft lbs.

3. Assemble the cork washers and hydraulic units.

4. Adjust the tappets as described in "Valve Tappet Adjustment."

CLUTCH



Glide Models

DISASSEMBLY

1. Remove the chainguard of chain housing cover.

2. Remove the pushrod adjusting screw locknut and place a ⅛ in. thick washer of 1¾ in. diameter, with a ⅜ in. hole, over the adjusting screw.

3. Secure it with a locknut and tighten until the spring guide stud nuts are free.

5. Slide out the friction and steel discs.

6. Loosen the starter motor to provide clearance for removing the clutch sprocket and chain.

7. Remove the engine sprocket nut with Sprocket Nut Wrench (H-D Part No. 94545-26) or a suitable substitute and pull the sprocket off the shaft. A 1.0 in. socket can also be used.

8. Lift the primary chain so that it is free from the clutch sprocket and remove the clutch sprocket.

9. Remove the clutch gear nut and washer using H-D Clutch Hub Nut Wrench, Part No. 94645-41. This nut has a left-hand thread, and the tool is best used in conjunction with a soft mallet. Any socket which fits the nut properly can also be used.

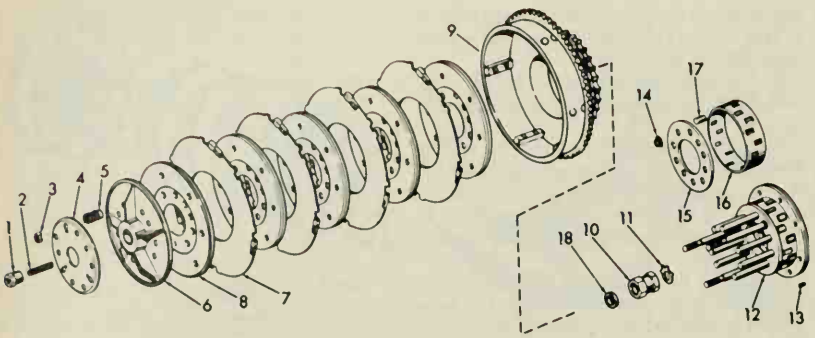
10. Pull the clutch hub with Claw Puller (H-D Part No. 95960-41A). Most small gear pullers will also work.

11. Remove the bearing plate springs from the hub pins.

12. Remove the bearing retainer from the hub.

INSPECTION

1. Clean all parts in a suitable solvent and blow them dry.



2. Examine all parts for wear and replace any friction disc linings that are glazed, grooved, worn down to the rivets, oil-impregnated, cracked or chipped.

3. Glazed friction discs can sometimes be salvaged by soaking them in white gas for several hours and roughing them with a medium grade sandpaper. Make certain that all traces of gas are removed before reinstalling. This is not a recommended practice but will serve temporarily.

4. Steel discs can be reused unless they are burned or grooved, or if buffer balls do not snap back when depressed.

5. Replace the clutch hub roller bearing if, after cleaning and repacking, it sticks or fails to revolve smoothly.

6. Clutch springs may be tested for compression with the Valve Spring Tester, Part No. 96797-47 or an automotive tester. 1967 and earlier models have springs whose free length is $1^{31}/_{64}$ in.

and compress to 42–52 lbs at 1⅛ in. 1968 and later models have a free length of 1 45/64 in. and compress to 30–38 lbs. at 1¼ in. Springs not meeting these specifications should be replaced.

ASSEMBLY

1. Assemble the springs on the releasing disc and place the pressure plate on them, taking care to seat each spring properly.
2. Turn the pushrod adjusting screw into the releasing disc.
3. Lay the washer, as described in "Clutch Disassembly," loosely over the adjusting screw and secure it with the pushrod adjusting screw locknut.
4. Before securing the locknut, check spring alignment and correct if necessary, using a ⅜ in. rod as an aligning tool.
5. Place the hub on the gear shaft with the splines engaged, and secure it with the lockwasher and gear nut. Set the washer in one of the nut's slots with a punch.
6. Slide the clutch sprocket and key ring on the hub.
7. Light grease the ball bearings.
8. Slide the clutch discs on in the order shown in the illustration. The disc which is closest to the hub should be a friction disc, then a steel disc, and so on with buffers staggered in different spline ways. Steel discs are installed with the "out" stamp facing out.
9. Slip the releasing assembly on the hub studs, and secure it with the spring guide stud nuts as described in "Clutch Spring Adjustment."
10. When reassembling, the back of the pressure plate to the front of the clutch releasing disc is 31/32 in. for 1967 and earlier models, and 1 1/32 in. for 1968 and later models.
11. Adjust the clutch control and release lever.

Sportster

RELEASE MECHANISM

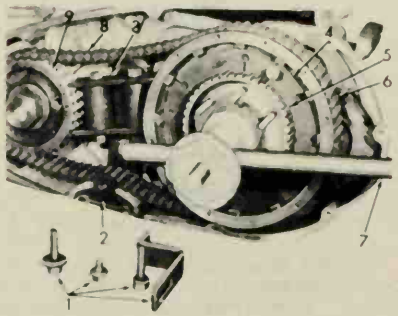
Disassembly

1. Remove the sprocket cover and disengage the clutch cable.
2. Disengage the spring, remove the adjusting screw locknut and screw and the worm cover.
3. Remove all clutch parts labeled 1–10 in the illustration to remove the clutch release rods.
4. The left clutch release rod will slip out and the other three must be drifted out from the clutch side.
5. The roll pin is a press-fit and should not be removed.

Inspection

1. Clean all parts with a suitable solvent and blow dry.
2. Inspect the worm for wear and replace if necessary. Excessive wear will cause clutch drag.
3. Examine the fit of the lever fingers with cable end, and replace if not firm.
4. The correct length of the lever spring is 1 25/32 in. and must be replaced if worn or damaged.
5. Examine the tips of the clutch release rods for wear, roll the rods on a flat surface to check for warping, and replace if necessary.

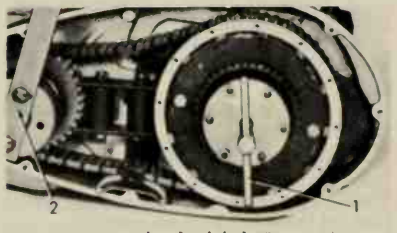
Assembly



Assemble in reverse order of disassembly. Note the following:

1. Dip the rod ends in oil before installing.
2. Slip in the left release rod from the clutch gear end, and slip in the left center, right center, and right release rods from the sprocket side.
3. Assemble clutch parts 10-1 (see illustration) as described in the "Clutch Assembly" section.
4. Assemble the worm, spring, cover, adjusting screw, and locknut to the sprocket cover and check for smooth movement.
5. Place the cover on the starter shaft and engage the cable end with the lever; secure the cover.
6. Lubricate the worm with a suitable grease through the worm fitting.
7. Check the motion of the worm and be sure it seats against the roll pins.
8. Install the remaining parts.
9. Adjust the clutch release mechanism.

1970 AND EARLIER CLUTCH



Disassembly

1. Remove the chain and clutch covers, and all associated hardware.
2. Remove the hub stud nuts, spring-tension adjusting plate, spring cups, and releasing disc.
3. Slide out the 14 clutch plates and backing plate by tipping the engine or lifting them out with a hooked piece of wire.
4. Remove the primary chain adjuster brace capscrews and brace.
5. Use a Sprocket Locking Link Tool (H-D Part No. 97200-55), if available, to prevent the clutch and compensating sprocket from turning while pulling the hub. A wooden door stop wedged in below the compensating sprocket or a suitable air impact driver are alternatives which will also work.

Clutch assembly (Sportster, 1970 and earlier)

(H-D Part No. 95960-52) or suitable gear puller.

11. On 1967 XLH models, remove the O-ring from its groove in the clutch gear.

12. Remove the gear shaft nut by using the Compensating Sprocket Shaft Wrench H-D Part No. 94557-55), and remove the clutch shell, primary chain, and engine sprocket. As an alternative method, punches can be inserted in the sprocket holes, and levered with a screwdriver.

13. Remove the clutch hub spacer.

14. Remove the clutch gear extension and O-ring by tapping it with a soft mallet. This applies only to 1966 and earlier models.

Inspection

1. Inspect the clutch cover for damage which might cause leaks and use a new gasket for reassembly.

2. New springs have a free-length of 1⅝ in. and if any spring is too short, damaged from heat, or worn, the set should be replaced.

3. Inspect the clutch release disc for grooves, excessive wear, or a warped condition, and replace if necessary.

4. Inspect the clutch friction plates for wear, grooves, or oil saturation. If the plates are worn but not oily, they may be cleaned with medium grade sandpaper.

5. Driven clutch plates can be reused if they are only slightly discolored but they must still be smooth.

6. Replace the hub nut lockwasher.

7. Inspect the clutch hub spacer and needle bearing for excessive play and wear. Replace the spacer, if necessary.

8. Carefully pry the oil seal from the clutch sprocket and expand it to check for wear or damage. Replace if in doubt or if hairline cracks are present.

9. Examine and replace the clutch shell if excessive wear, grooving, worn or loose keys, worn or broken teeth, loose rivets, or a damaged sealing surface is present.

10. Loose rivets can be replaced if this is the only fault. Set the rivets until they are flush to 0.010 in. above the starter clutch face or 0.080 in. between the rivet head and bottom of the sprocket tooth for key securing rivets. Seal both sides with a solvent-proof sealer.

11. Inspect the starter clutch teeth for wear or damage, and consult the "Clutch Sprocket Needle Bearing and Starter Clutch" section for replacement procedures.

12. Inspect the clutch gear oil seal, by expanding the seal surface, and replace it if hair line cracks or other damage is present.

13. Replace the clutch hub rubber O-ring, if it is worn or damaged.

CLUTCH SPROCKET NEEDLE BEARING AND STARTER CLUTCH REPLACEMENT

1. Remove the oil seal and sprocket rivets to gain access to the clutch sprocket needle bearings, washers, and starter clutch. Bearings and the sprocket hub washer pin are a press-fit.

2. Replace the bearing by pressing from the inside on the bearing's printed side to a depth of 0.025–0.029 in. from the shell's inner face to the bearing's lip.

3. Press the roll pin until it extends 0.08 in. from the sprocket face.

4. On 1967 XLH models, the two bearings are pressed in the same way. The first seats to 1.010–0.015 in. from the shell to the bearing's inner face, the second is pressed from the starter clutch side until it is flush with the first.

5. Align the hub washer countersunk hole with the washer pin and mount the washer.

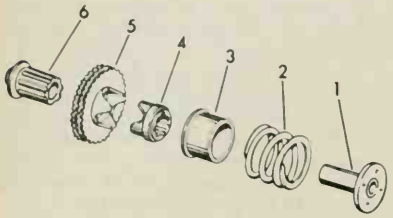
6. Insert the appropriate sized variable washer in the starter clutch.

7. With the starter clutch on the back plate, check clearance between the washer and the clutch with a feeler gauge. Exert pressure on the plate and try different washers until 0.001–0.0021 in. clearance is arrived at. Washers come in thicknesses which vary by .002 in.

8. Insert the rivets into the countersunk holes from within the shell and set to 0.010 in. maximum above the clutch face. Seal both sides of the rivets with a solvent proof sealer.

9. Press the hub oil seal in place with the lip facing into the shell.

COMPENSATION SPROCKET



Removal

1. Loosen the clutch shell and primary chain as described in "Clutch Disassembly."

2. Remove the sprocket shaft nut using Shaft Nut Wrench (H-D Part No. 94557-57) or a one-inch hex socket or wrench.

3. Slip the spring, sliding cam sleeve, sliding cam sprocket, and primary chain

and clutch shell off shaft as an assembly. Use Sprocket Shaft Extension Puller (H-D Part No. 96015-56) or a suitable substitute to remove the shaft extension if desired.

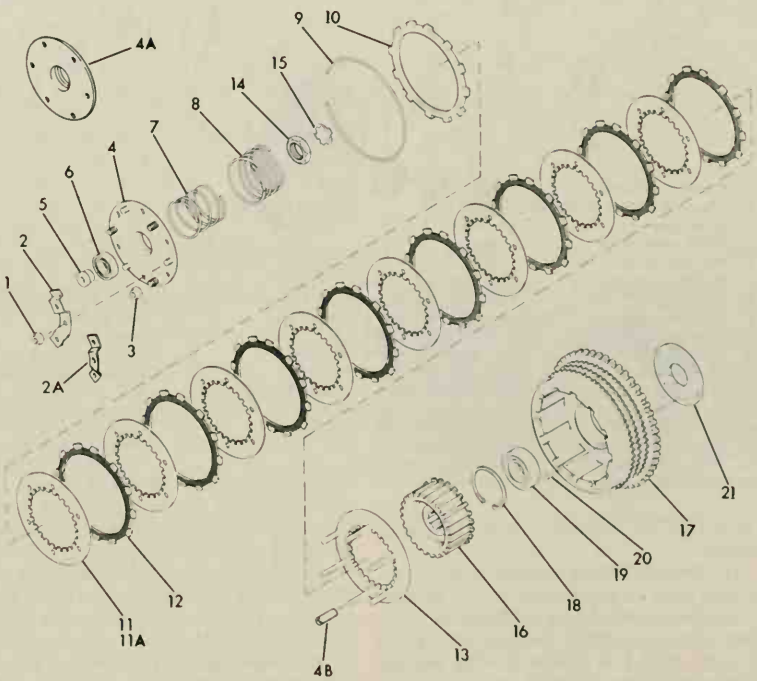
Inspection

1. Clean all parts with a suitable solvent and blow them dry.
2. Inspect the sprocket teeth, shaft splines, and sliding surfaces for excessive wear or damage, and replace if necessary.
3. The cam and extension must be a matched set, so replace both or neither.
4. If the spring is damaged there will be primary chain noise even when the chain is properly tensioned. Replace it if this is the case.

Installation

1. Set the shaft extension with Sprocket Shaft Bearing Tool (H-D Part No. 97081-54) as described in the "Crankcase Assembly" section. A socket can also be used as a drift.
2. Lightly grease the extension splines and assemble the sprocket, chain and clutch shell.
3. Slide on the sleeve, spring, shaft nut, and cam, taking care to align the splines.
4. Secure the clutch shell and sprocket shaft nut.
5. Assemble the chain cover and associated hardware.

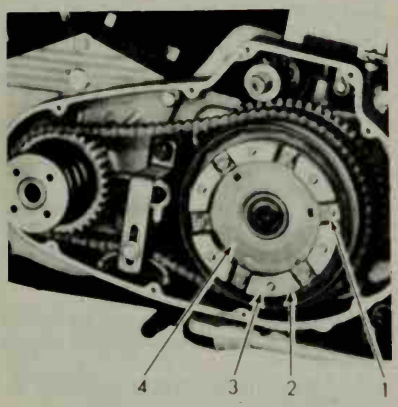
1970 AND EARLIER CLUTCH



Assembly

1. All parts must be clean, dry, and oil-free.
2. Lightly coat the release rod tips in oil and slide them into the clutch gear with the right rod first, then the right center, left center, and left rod last.
3. On 1966 and earlier models, press the gear extension into the clutch gear and seal it with aluminum paint.
4. Insert the hub nut O-ring and oil seal.
5. Lightly grease the needle roller bearings and compensating sprocket shaft extension.
6. Press-fit the roller bearing in the clutch shell.
7. Install the hub spacer and O-ring on the clutch gear.
8. Assemble the compensating sprocket as described in "Compensating Sprocket Assembly." The chain adjuster should be loose behind the chain.
9. With Clutch Hub Installing Tool (H-D Part No. 97170-55) install the hub on the gear splines. A socket can be used in conjunction with a soft mallet.
10. Install Locking Plate (H-D Part No 9175-55) and lock the sprocket as described in "Clutch Disassembly" Step 5.
11. Slip a new lockwasher over the clutch gear splines and install the hub nut with an appropriate sized wrench or special Wrench (H-D Part No. 94647-52). Seat the nut to at least 150 ft lbs torque by striking the wrench handle with a soft mallet.
12. Bend the washer ear against the hub nut.
13. Check to make sure that the hub runs free on the shaft and check clearance between the starter clutch gear and starter clutch as described in the "Starter Assembly" section.
14. Adjust the primary chain.
15. Remove the hub locking tools.
16. Install the backing plate against the back of the hub with the grooved side out.
17. Assemble the clutch plates starting with a steel plate, then a friction plate and so on. The last plate should be a friction plate and all should move freely.
18. Install the releasing plate on the hub with the studs centered in the cup holes. The larger of the two grooves on the rim should line up with the hub's notched tooth.
19. Assemble the cups, springs, and pressure plate with the raised surface facing out.
20. Place the ½ in. long nut on the longer studs and tighten them evenly until the shorter studs are available. Start the 7/16 in. nuts on their studs.
21. Tighten all six nuts evenly until the inside of the pressure plate is 3/16 in. from the cup flanges. This is the proper distance for new clutch plates.
22. Assemble the new cover gasket with the graphite side facing out. Do not use sealer.
23. Assemble the clutch cover, screws, and screw retainers. Lightly stake the retainers to the screws.
24. Install a new chain cover gasket and apply sealer to both sides. Mount and secure the chain cover.

1971 AND LATER CLUTCH



Disassembly

1. Remove the chaincase cover.
2. Remove the retainer nuts and retainer.
3. Install the Clutch Spring Compressing Tool (H-D Part No. 97178-71) if available. The new clutch has a center spring configuration rather than the traditional six springs. The pressure on the

5. Remove the retaining ring from the clutch shell groove and pull all of the clutch plates free as a unit by pulling on the pressure plate studs.

6. Consult "1970 and Earlier Clutch Disassembly" to complete disassembly.

Inspection

1. Inspect the clutch springs for heat damage and replace any spring under the following free-length limits: inner springs are to be 2 5/16 in.; 1970–71 outer springs are to be 1¾ in., and 1972 and later outer springs are to be 2½ in.

2. If the clutch shell bearing action is rough or has excessive play, it may be replaced by arbor-pressing it in and out after the retaining ring is removed with snapring pliers.

3. Check the releasing disc bearing action for roughness or excessive play and replace if necessary.

4. Consult "1970 and Earlier Inspection" for additional procedures.

Assembly

1. Consult "1970 and Earlier Clutch Assembly."

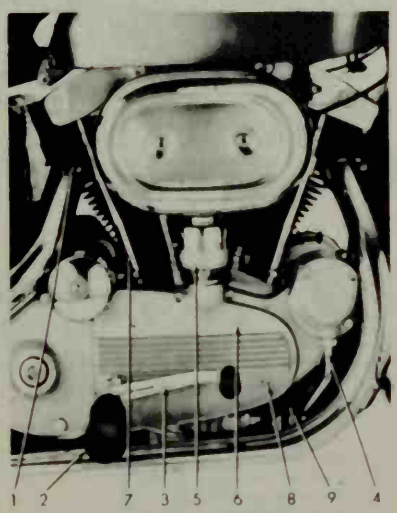
2. On late 1974 and later machines, be sure the stud spacers are installed.

3. The clutch nuts (1971–early 1974) should be tightened to yield a distance of 11/32 in from the outer drive plate to the outer side of the releasing disc.

TIMING GEARCASE

Sportster

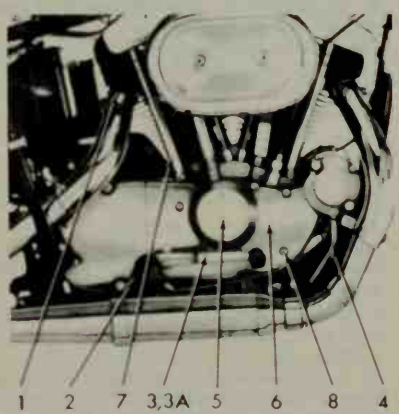
DISASSEMBLY



1. Remove the exhaust pipe assemblies, footrest, shift lever, or footrest and brake pedal on 1975 and later bikes, breather pipe, contact breaker or magneto, as described in "Contact Breaker Assembly" or "Magneto Removal," and pushrods as described in "Pushrod Removal and Installation."

2. Drain the oil, remove the gearcase cover screws, and remove the cover from its dowel pins by tapping it with a soft mallet or hammer and wood block where the cover projects beyond the gearcase. Remove the cover gasket.

3. Remove the tappets and guides.



4. Disconnect the clutch cable.

5. Remove the rear cylinder exhaust, rear cylinder intake, front cylinder exhaust, and front cylinder intake cam gears and cam gear plates. Gear lobes are numbered from 1–4 to designate their positions from the back to the front of the gearcase. Remove and separate the gear shaft shims for replacement in their original positions.

7. Remove the pinion gear with Pinion Gear Puller (H-D Part No. 96830-51) or a suitable substitute.

8. Remove the oil pump drive gear.

INSPECTION

1. Clean all of the parts except the cover gasket in a suitable solvent and blow dry with compressed air.

2. Clean the inside of the gearcase, taking care to keep the solvent from soaking through the crankcase.

3. Inspect all parts for wear or damage and replace as necessary. Bushings need not be removed unless wear or damage makes replacement necessary.

4. Inspect the crankcase oil screen for a clogged condition and clean or replace as necessary. Probe the screen hole with a hooked piece of wire to check for foreign objects.

5. Replace the idler gear bushing or shaft if worn.

6. Replace the gear assemblies when excessive lash is present, the teeth are damaged or the cams are worn or pitted.

7. Blow the crankcase relief pipe clear with compressed air.

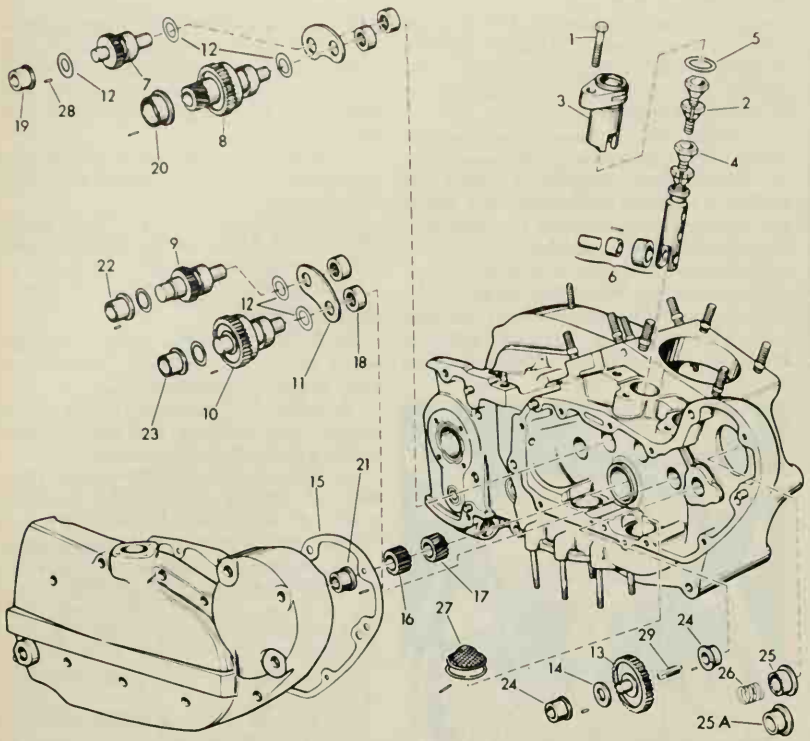
8. Inspect breather oil separator seal ring for free action.

9. If shaft clearance in the cover bushings exceeds 0.0005–0.001 in. by 0.001 in. or more, bushing replacement is necessary. Replace the bushings also if the flanges are worn.

10. If the shaft clearance in the bearings exceed 0.0005–0.0025 in., bearing replacement is necessary.

11. Inspect the cam gear plates for wear or damage and replace if necessary.

12. Replace the pinion gear if clearance is present, since any lash will cause noisy operation.



13. Oil separator bushings must have free-play and 1/16 in. running clearance with the generator oil slinger washer.

14. Remove the cam gear needle bearing with needle bearing puller (H-D Part No. 95760-69 or disassemble the crankcase as described in "Crankcase Disassembly" and arbor press them out. Press on the printed side of the bearing only when replacing, (Tool No. 97273-60) taking care to press the bearing in absolutely straight. Laying a flat piece of metal over the bearing will protect it. Press until flush with the mating surface.

15. Remove the gearcase cover bushings with crankcase cam gear shaft bushing remover (H-D Part No. 95760-69), or a suitable substitute.

16. Drift the crankcase bushings out from the flywheel side with a suitable drift, or use the above special tool if the crankcase is still assembled.

17. Press the front cylinder exhaust bushing into the gearcase cover with the oil hole toward the rear of the cover. Place a flat plate over the flange to protect it, and press until the flange sits flush on

18. Press the front and rear cylinder intake bushings into the gearcase cover with the narrow section of the flange pointing downward. Repeat the above drilling operation.

19. Press the rear cylinder exhaust bushing flush with the oil feed pump seat from the outside. Repeat the above dowel pin installation, but do not peen the bushing.

20. Press the pinion gear shaft bushing into the cover with the oil hole pointing 30 degrees forward of its vertical centerline.

21. Arbor-press the crankcase side bushings in place, with the crankcase disassembled, from the gearcase side with the flange notch pointing upward. Repeat the above pin securing procedures.

22. To line-ream the cam gear and timer bushings, insert the Camshaft and Timer Shaft Bushing Reamer (H-D) Part No. 94803-37) "T" portion through the right crankcase from the flywheel side without turning the reamer and assemble the larger portion of the tool. Start the larger portion in the timer shaft bushing and assemble the gearcase cover. Always secure the cover with at least four screws when reaming and always turn the reamer to the right until bottom is reached, then withdraw it while still turning to the right. A suitable substitute reamer may be used if care is taken.

23. Line-ream the pinion shaft bushing with Pinion Shaft Bushing Reamer (H-D Part No. 94812-37) or a suitable substitute. The cover must be assembled and a guide bushing must be used.

24. Ream the rear cylinder exhaust cam gear bushings with Oiler Shaft Bushing Reamer (H-D Part No. 94811-36) or a suitable substitute. Work from the gearcase cover side.

25. Using only the smaller reamer of the Cam Shaft and Timer Bushing Reamer (H-D No. 94803-37) or a suitable substitute, line-ream the front cylinder exhaust and intake bushings, taking care not to remove more metal than necessary.

CAM GEAR END PLAY

End play must be checked before final assembly.

1. Temporarily install the two cam gear plates without the shims. The bevelled side of the shaft holes should face outwards towards the cams.

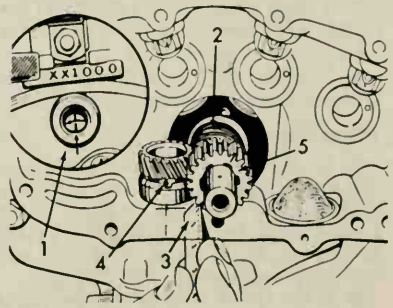
2. Install the cam gears. Assemble the case cover with gasket dry and tighten it securely.

3. Turn the engine over until the No. 1 cam gear lobe is facing up (look through the tappet guide hole in the crankcase).

4. Pry the cam gear towards the case cover with a screwdriver. With a feeler gauge, measure the clearance between the camshaft shoulder and the gear plate. It should be 0.001–0.005 in.

If necessary, add the proper number of 0.005 or 0.007 in. shims until end play is correct.

5. Repeat the procedure with the remaining gears.



6. Check that the gears rotate freely.

BREATHER VALVE TIMING

1. Turn the engine until the flywheel timing mark is directly in the center of the inspection hole.

2. Install the spiral gear, the marked side facing towards the pinion gear. The gear must be fitted so that the timing hole in the breather sleeve gear is in the center of the slot in the breather bushing.

3. Install the pinion gear. The pinion gear outer face must be exactly 5/16 in. from the gearcase joint face.

3. Install the idler gear with the fiber washer on the cover side.

4. The remainder of the procedure is the reverse of disassembly.

Glide Models

DISASSEMBLY

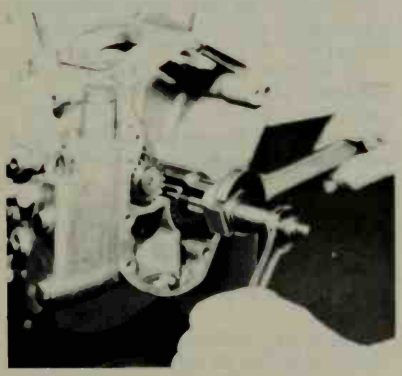
1. Remove the pushrods, tappets, hydraulic units, and tappet guides.

2. Remove the oil screen cap, gasket, springs, and screen.

3. Remove the circuit breaker assembly including breaker cam and advance assembly.

4. Remove the gearcase cover screws and tap the cover with a plastic mallet or the like to remove it. 1973 and later cover and gasket are different from earlier models.

5. Remove the breather valve spacing washer and gear.



6. Remove the cam gear, spacer, and thrust washer.

7. Remove the pinion gear shaft nut (left-hand thread). Pull off the pinion gear with Part No. 96830-51. The tool has left-hand threads.

8. Remove the key, gear shaft pinion spacer, oil pump pinion shaft gear, and key.

9. Remove the oil pump drive gear shaft lockring, drive gear, and key.

10. Remove the oil pump.

Removing the pinion gear

INSPECTION

1. Inspect the oil screen. Clean or replace if damaged or plugged.

2. Inspect the cam gear and gear bushings for wear. If bushing to shaft clearance exceeds the standard specification by 0.001 in. or more, install new bushings.

3. Check pinion shaft play in the right main roller bearing. Replace the bearings if play exceeds the standard specification by 0.001 in. or more.

4. Check the needle bearing for wear. If the camshaft is worn 0.003 in. or more, replace the camshaft and bearing.

5. To remove the needle bearing use Tool No. 95760-69 which does not necessitate splitting the crankcases. Install with No. 97272-60 pressing it in from the end with manufacturer's stamp. Install new bearing from the gearcase side.

6. Pinion shaft main roller bearings are replaced after splitting the crankcases.

7. Check the gears for wear. Assemble the pinion and cam gear without end spacer and check that there is no backlash and that the cam gear can be moved back and forth along the shaft axis without restriction.

8. To replace the gearcase cover bushings, remove the pinion shaft cover bushing with Tool No. 95760-69.

9. To install a new bushing, position it so that the bushing oil hole is directly in line with the lubrication channel outlet in the cover. Press in the bushing until the top is flush with the bushing boss in the cover. Center punch a new dowel pin location at least ⅛ in. from the original location. Drill No. 31 is used to make a hole 3/16 in. deep. Press in bushing until it bottoms on the shoulder in cover hole. Continue drilling dowel pin hole to 9/32 in. from top to bushing. Install a new dowel pin and peen edges of hole to lock the pin in place. On 1973 and later models, the flat on the bushing must line up with the oil hole in the cover.

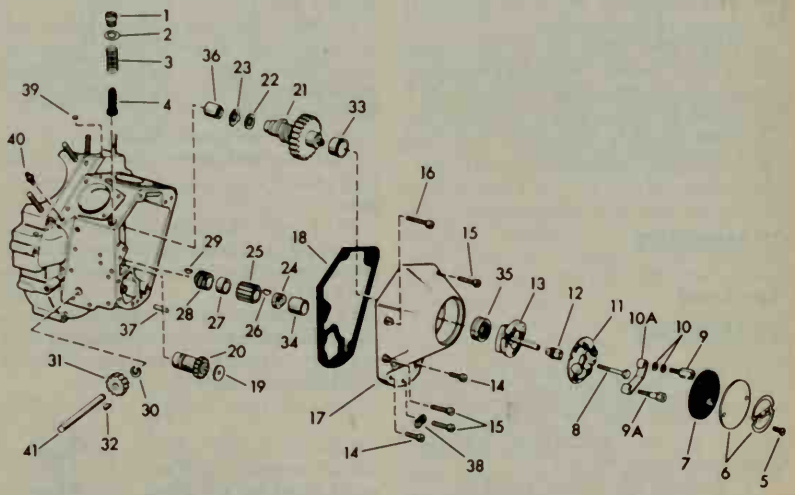
10. To replace the camshaft cover bushing, use Tool No. 95760-69 to remove the old bushing.

11. Make a mark on the outside of the bushing boss to locate the original dowel pin hole. Press in a new bushing until the shoulder is against the cover boss. Locate a new dowel pin hole at least ⅛ in from the original hole. Drill a No. 31 hole exactly 9/32 in. deep. Install a new pin and peen the edges over to secure it.

12. Drill a 5/32 in. lubrication hole through the bushing, using the oil hole in the bushing boss as a guide.

13. The bushings must be line-reamed. To ream the pinion shaft bushing, insert the reamer pilot into the right crankcase roller bearing race.

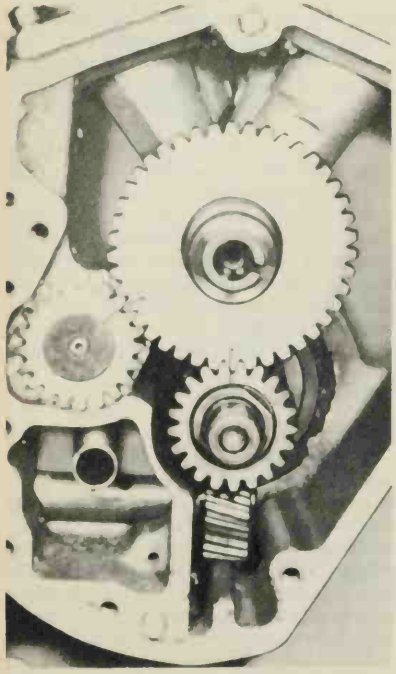
14. Insert a 9/16 in. pinion shaft cover bushing reamer (No. 94805-57) through the pilot and push into cover bushing until it bottoms. Then turn it one turn. Rotate the reamer in the same direction during extraction.



15. To ream the cam gear cover bushing, use a 1 in. expansion reamer and ream to 1.002–1.003 in.

ASSEMBLY

1. Check breather gear end-play. Assemble the breather gear and gasket to the case. Install the spacer washer on the end of the breather gear. Place a straightedge across the gearcase at the spacer. Measure the distance between the straightedge and the spacer. Subtract 0.006 in. (gasket compression). The resultant figure is the end-play. It should be 0.001–0.005 in. If greater, insert a thicker spacer.



2. Check cam gear end play. Install the thrust washer, spacer, and cam gear. Position the gasket and secure the cover.

3. Measure the end-play between the cam gear and the cover bushing through

DISASSEMBLY

1. Remove the engine from frame.
2. Remove the cylinders and pistons.
3. Remove the oil pumps as described in the "Lubrication Systems" section and drain the oil.
4. Remove the contact breaker.
5. Remove the generator and starter.
6. Remove the tappets.
7. Remove the sprocket shaft extension with a sprocket shaft extension puller (H-D Part no. 96015-56) or a suitable substitute. Solid sprocket models can be removed with a claw puller.
8. Remove the speedometer drive unit, right crankcase bolts, stud lock nuts, rear mount bolts, battery carrier or oil tank bracket, rear engine mount, and top center crankcase stud.
9. Loosen the top of the crankcase by tapping it with a soft mallet and separate the cases.
10. Pry the pinion bearing shaft snapring from the shaft and remove the shaft bearing washer, roller bearings, and bearing retainers.

13. Remove the Timken bearing right half with a sprocket shaft bearing puller (H-D Part No. 96015-52) or a suitable substitute if flywheel is to be disassembled or if the bearing is to be replaced.
14. Pry free the sprocket shaft oil seal and spring with a pointed instrument and replace both.
15. With the crankcase clutch side supported by parallel bars, place the right half of the bearing on the left and arbor-press out the bearing spacers, left half, and outer race.
16. With the pinion shaft secured in a copper or wood-jawed vise, remove the lock plate screw, lock plate, and crankpin nut.
17. Loosen the left flywheel by striking its rim at a point 90 degrees from the crankpin with a soft mallet and remove the flywheel.
18. Separate the connecting rods from the crankpin bearing by holding the bearing with a suitably sized piece of pipe and lifting the rods free.
19. Remove and separate the bearing for reassembly.
20. Remove the lock plate screws, lock plates, and sprocket and crank pin lock nuts.
21. Tap the flywheels with a soft mallet to loosen the shafts and remove the shafts and keys.

INSPECTION

1. Clean all parts in a suitable solvent and blow dry. Blow all oil holes clear.
2. Inspect all parts for a worn, pitted, or damaged condition and replace if necessary.
3. Replace the rods, bearing, and crankpin as an assembly if parts are excessively worn.
4. Inspect the pinion shaft bushing and shaft for wear or damage and replace if necessary.
5. Inspect the sprocket shaft bearing assembly for wear or damage. Timken rollers must be replaced in sets.
6. Replace worn or damaged flywheel thrust washers in the following manner:

a. Drill a hole slightly deeper than the washer on its outer edge using a ⅛ in. drill.

Crankcase assembly

1. Crankcase mounting bolt $^{5}/_{16}$ x 4-$^{5}/_{16}$"
2. Crankcase mounting bolt $^{5}/_{16}$ x 4-$^{1}/_{16}$"
3. Crankcase mounting bolt $^{5}/_{16}$ x 2-$^{3}/_{4}$" (3)
4. Crankcase rear maunting stud and lock nut (3)
5. Engine rear maunting bolt and lockwasher (4) (1966 and earlier), (2) (1967 and later)
6. Battery carrier (1966 and earlier)
7. Engine rear maunt (1966 and earlier)
7A. Engine rear mount (1967 and later)
8. Crankcase bolt (2)
9. Crankcase stud and lock nut (center)
10. Crankcase (1966 and earlier)
10A. Crankcase (1967 and later)

Figure following name of part indicates quantity necessary for one complete assembly.

b. Pry the washer free with a pointed tool.

c. File the staked flywheel material smooth with emery paper and thoroughly clean the washer seat.

d. Insert a new washer taking care to seat it fully.

e. Secure the washer by center punching the flywheel around the washer.

7. Lap worn connecting rod races until there is no wear on the shoulder and both rods will accept the same size rollers. The lapping tool must fit in the bearing race snugly before compound is applied. Connecting rod lapping arbor (H-D Part No. 96740-36) or a suitable substitute, used at 150–200 rpm in a lathe, will provide the best results. Use a smooth motion.

8. Secure the pinion shaft to the right flywheel making sure all parts are completely clean.

9. Secure the pinion shaft key.

10. Secure the pinion shaft in a copper or wood-jawed vise and tightly secure the pinion shaft nut with a crankpin and flywheel nut wrench (H-D Part No. 94546-41) until the lockplate notches line up with the nut edges. Do not use additional leverage as damage will result.

11. Secure the crankpin and nut in the above manner.

12. Fit the rod bearings in the following manner:

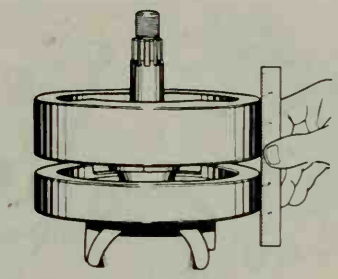
a. Assemble the thoroughly cleaned sprocket and pinion shafts to the flywheel. If the lockwasher screw holes won't line up, increase the tightness of the shaft nut.

b. Secure the crank pin in the left flywheel.

c. Secure the flywheel and sprocket shaft with the crank pin in a vertical position in a copper or wood-jawed vise.

d. Install a connecting rod bearing set on the crankpin and check for a plug fit of both rods. If necessary, lap the tighter of the two rods until both are even.

e. Check for correct fit by subtracting one half the specified running clearance from the roller size.



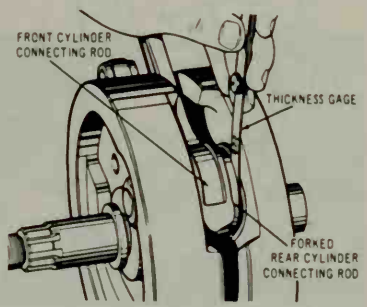
f. The upper end rod furthest from the flywheel should have side shake of $^{1}/_{32}$–$^{3}/_{64}$ in. Bearings must not extend beyond the rod edges.

13. Replace the pinion shaft bushing and bearing. Place the arbor guide sleeve (H-D Part No. 96728-56), or a suitable substitute, through the Timken bearing from the inside of the case, and fit the bearings to a running clearance of 0.0008–0.001 in. A slightly looser fit is recommended for sustained high speed driving.

ASSEMBLY

1. Secure the thoroughly cleaned left fly wheel and sprocket shaft in a copper or wood-jawed vise and assemble the crank pin and right flywheel.

2. Check flywheel alignment with a straight edge. Alternately tighten the crank pin nut slightly and recheck alignment until secure. A soft mallet can be used to aid alignment. This method generally provides alignment to within 0.002 in.



Checking flywheel alignment

3. Press one rod against the flywheel thrust washer and measure play between the opposite rod and washer with a feeler gauge. Check for the following if play is less than 0.006 in.:

a. Flywheels and crank pin tapers were oily during assembly allowing crankpin nuts to be overtightened.

b. Flywheel thrust washers are improperly seated.

c. Flywheel tapered holes are worn to excessive clearance.

Measuring rod side clearance

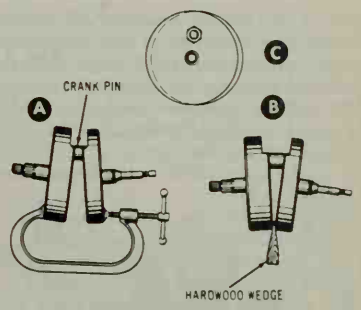
d. Cracks at the flywheel tapered holes.

4. If play is greater than 0.010 in., wait until the flywheels are trued before correcting.

5. True the flywheels with a truing device (H-D Part No. 96650-30) in the following manner:

a. Place the flywheel assembly in the device and adjust until the centers are snug.

b. Rotate the flywheels and mark the high point with chalk. Loosen the device slightly and align using the three following methods.



NOTE: *(A) or (B) should be done before (C).*

(A). A C-clamp can be used on the rims directly opposite the crankpin along with moderate blows to the rim at the crank pin with a soft mallet.

(B). A hardwood wedge can be driven between the wheels directly opposite the crankpin. Moderate blows with a soft mallet are the safest way to perform this operation.

(C). Strike the wheel, at about 90 degrees from the crank pin, with a firm blow with a soft mallet.

c. Repeat Steps (A) and (B) above. If truing procedures were effective, shaft play should be 0.001 in. or less. The factory device has 0.002 in. gradations. Check for a cracked flywheel, enlarged tapered hole or worn sprocket or pinion shafts if repeated truing attempts fail.

Aligning the flywheels

d. Secure the crank pin nuts tightly when the flywheels are true, then recheck on device. Minor adjustments may be made without loosening the crankpin nuts.

6. An alternate method is to use a dial indicator, and a lathe or some other means of rotating the flywheels on a steady plane.

7. Replace the sprocket shaft bearing inner spring ring.

8. Support the left crankcase, crankcase side up, on an arbor press and press the Timken bearing outer race in until it seats on the spring ring. Sprocket shaft bearing tool (H-D Part No. 97081-54) or an arbor press may be used for all of these operations.

9. Secure the flywheel assembly in a copper or wood-jawed vise with the sprocket shaft up.

10. Install a flywheel support plate (H-D Part No. 96137-52) or a suitable substitute between the flywheel halves.

11. Press the bearing right half on the shaft with a 1 in. I.D. (inside diameter) x 6 in. steel tube until the bearing seats on the shaft shoulder.

12. Slip the sprocket shaft bearir spacer in place and lubricate the beari with engine oil.

13. Insert the sprocket shaft through the bearing outer race in the left and press the left half of the bearing in place until it is seated, taking care not to damage it. Both bearing halves must be tight against their spacers.

14. Place the notched side of the sprocket shaft bearing spacer on the shaft and gently press it into place or use a suitable screw type extractor until the spacer is tight against the outer bearing race.

15. Install the outer spring ring and oil seal with the lipped side in.

16. Press the sprocket shaft extension in place until seated with the shaft and extension splines aligned.

17. Assemble the pinion shaft bearing, bearing washer, and a new bearing snap-ring, taking care to seat the snap-ring in the shaft groove.

18. Measure the flywheel end-play with a flywheel end-play gauge (H-D Part No. 96700-38) on the sprocket shaft.

19. Adjust the gauge pin until it gently touches the case. Push the shaft to the left and measure the clearance with a feeler gauge.

20. A dial indicator can also be used by securing the indicator so that the plunger gently contacts the shaft, then shift the shaft and measure as above.

21. Adjust flywheel end-play within the crankcase to 0.009-0.013 in. by using the appropriate steel thrust collar. Collars are available in 0.004 in. gradations from 0.066-0.102 in.

22. Assemble the remaining parts in the reverse order of disassembly.

23. Assemble the transmission as described in "Transmission Assembly."

24. Coat the crankcase joint faces with a non-hardening sealer.

25. Apply engine oil to the pinion shaft bearing; assemble and secure the crankcase halves

Glide Models

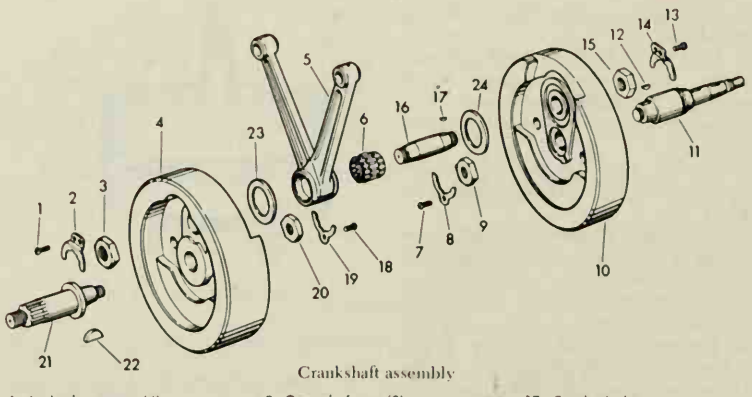
DISASSEMBLY

1–6. Same as for the Sportster.

7. Remove the gearcase assembly.

8. Remove the 3/8 x 3 1/4 in. crankcase bolts, 5/16 x 5 in. studs, breather stud and chain oiler, 5/16 x 6 in. stud, and 11/32 x 5 13/16 in. studs.

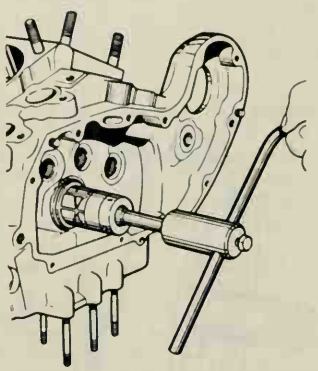
9. With the gear case side up, tap the crankcase with a soft mallet and remove the crankcase right half, spiral lock ring, and bearing washers and bearing retainer assembly.



10. Remove the sprocket shaft spacer (1968 and earlier models) and secure the pinion shaft in a copper or wood-jawed vise with the left case up.

11. Remove the left-hand threaded sprocket shaft bearing nut with the sprocket shaft bearing nut wrench (H-D Part No. 97235-55A) or a suitable substitute.

12. With the left case supported on parallel bars, arbor-press the sprocket shaft until the flywheel assembly comes free and remove the sprocket bearing half, washer, and spacer.



13. Pry the flywheel side outer snap-ring free (1968 and earlier models).

14. Arbor-press the bearing outer race press plug (H-D Part No. 97194-57) or a suitable drift to prevent damage to the races (1968 and earlier models).

23. Flywheel washer (2)
24. Flywheel washer (see item 23)

Lapping the pinion shaft bearing race

15. Using a suitably sized brass drift and hammer, tap the bearing race free from the opposite side. Remove the outer race snap-ring with a 1/8 in. punch or any suitable pointed instrument if the bearing set is to be replaced. This is easily done by tapping the ring through the oil hole (1969 and later models).

16. Consult Sportster "Crankcase Disassembly" for sprocket bearing inner half removal instructions. Use a bearing puller (H-D Part No. 96015-56). Leave the assembly in the vise.

17. Insert a 5 x 1/2 in. rod through the flywheel holes to secure them. Disassemble as directed in Sportster "Disassembly."

INSPECTION

Consult Sportster "Inspection."

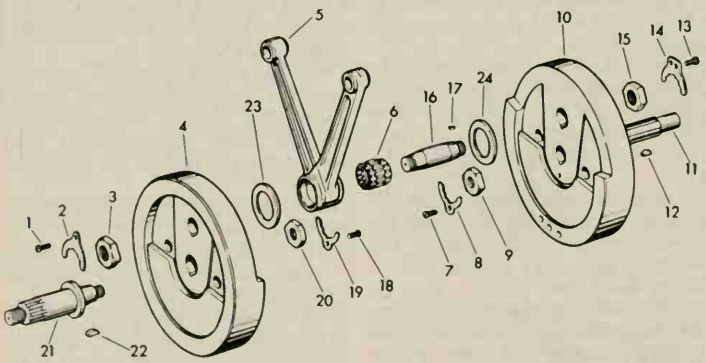
ASSEMBLY

Assemble in the reverse order of disassembly. Note the following:

1. Install the outer race snap-ring in the left case.

2. With the case supported on parallel bars, press the bearing outer races and snap-ring into the crankcase bushing. Use an outer race press plug (H-D Part No. 97194-57) or a suitable drift to press them in, one at a time, until sealed with the wider end out.

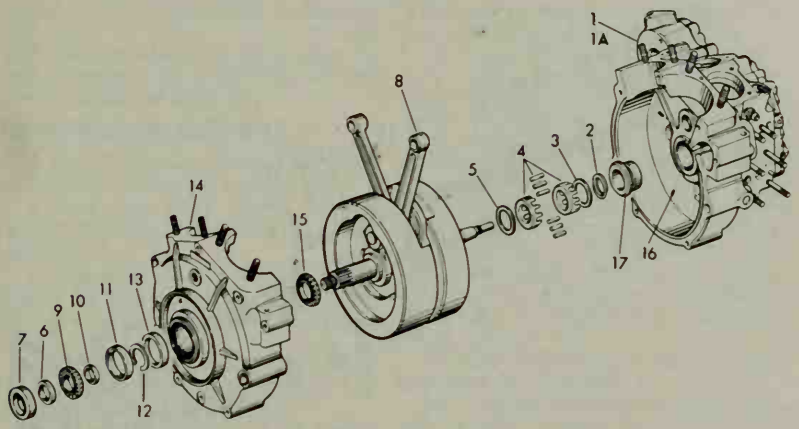
3. Install the bearing and spacer on the sprocket shaft, with the shaft in case and the outer bearing halves as described in Sportster "Crankcase Assembly."



4. The bearing must not be preloaded (under excessive tension). If shaking the case half does not reveal a slight amount of play in the case bearing half, or if the flywheel assembly will not rotate freely, the bearing must be removed and a 0.003 in. shim (H-D Part No. 23741-55) added to spacers. Assemble and recheck for play.

5. Slip the inner bearing washer, bearings, and outer washer in place on the pinion shaft and secure a new spiral lock ring in the shaft groove.

6. Apply a non-hardening sealer to the joint surface and secure the cases with the 5/16 x 6 in. and the 11/32 x 5 13/16 in. studs.



7. Consult Sportster "Crankcase Assembly" for flywheel end-play checking and correcting procedures.

8. Secure the case halves.

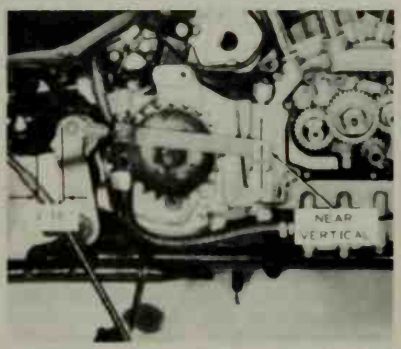
TRANSMISSION

Sportster

CRANKCASE AND TRANSMISSION DISASSEMBLY



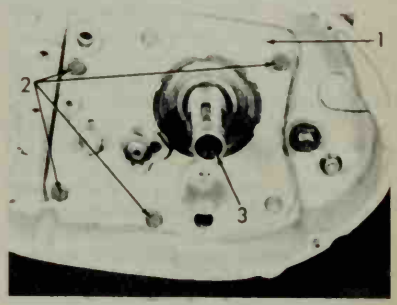
This section only applies if such work as overhauling the crankcase or flywheel is to be done. Otherwise the transmission can be serviced through the access cover.

1. Disassemble the crankcase as described in "Crankcase Disassembly."
2. Remove the first gear washer and first gear from the countershaft.
3. Free the assembled mainshaft.
4. Remove Second gear.
5. Remove the gear shifter cam cap screw and retainer ring, and then the shifter mechanism will come free of the access cover.
6. Remove the First gear washer, Third gear, and the shifter fork from the countershaft and remove the assembled countershaft.
7. For further information, consult "Shifter Mechanism Disassembly" and "Mainshaft and Countershaft Disassembly."

SHIFTER LINKAGE (1975 AND LATER)

Removal

1. Loosen the rear exhaust pipe at the cylinder and position it out of the way.
2. Remove the muffler for the front cylinder.
3. Remove the right footrest and brake pedal.
4. Remove the sprocket cover.
5. Mark the position of the shifter pedal relative to its shaft. Remove the pinch bolts and pull off the pedal.
6. On the right side of the machine, disconnect the rear end of the shifter link by removing the lockring and pulling the shifter link from the cross shaft arm.
7. The pivot end may be removed from the shifter link after loosening the locknut. When removing the pivot end, count the number of turns necessary to get it off the link for reassembly.



Shift linkage adjustment (1975 and later Sportster)

Installation

1. With the transmission in fourth gear, position the shifter pedal on its shaft so that it is ¼ in. from the bottom of the footrest rubber when at the top limit of its travel.
2. With the pedal in this position, the cross shaft arm should be 3/16 in. from the swing arm. Turn the pivot end in or out on its shaft to achieve adjustment.
3. If adjustment to these dimensions is not possible, proceed as follows: remove the gearcase cover. Remove the clevis lever from the shifter shaft after removing the pinch bolt. Mark the position of the lever on the shaft before removal. Move the lever one spline in either direction to achieve clearances outlined in Steps 1–2, above.

TRANSMISSION ACCESS COVER REMOVAL

1. With a drip pan under the clutch, remove the footrest, stoplight switch, brake pedal (74 and earlier) or shifter pedal (75 and later), chaincase cover, clutch, primary chain, and compensating sprocket assembly by consulting the "Clutch Disassembly" section.

Access cover

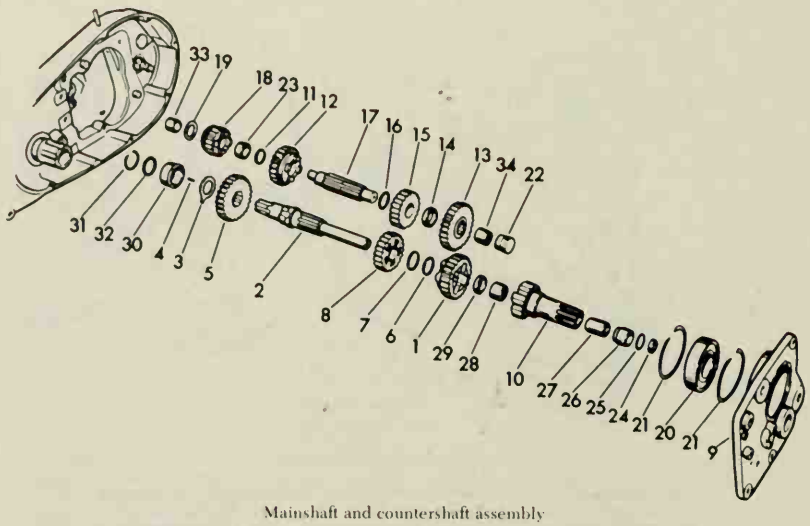
1. Access cover
2. Access cover capscrews (4)
3. Clutch gear oil seal
4. Hub nut rubber O-ring (XLCH, 1966 and earlier XLH)

2. Loosen the front cylinder exhaust pipe and muffler; remove the starter crank assembly, right footrest, and shifter lever. Remove the sprocket cover, starter crank gear, starter clutch gear, and starter crankshaft as described in the "Starter" section.
3. Loosen the mainshaft nut.
4. Remove the drive-chain master link and remove the chain.
5. Remove the mainshaft nut, lockwasher, sprocket, oil seal retainer screws and lockwashers, oil seal, seal retainer, and gasket from the mainshaft. If the sprocket requires assistance from a claw puller, make certain that at least two teeth are grasped by the puller or else damage will result.
6. Remove the access cover cap bolts.
7. Pry the clutch gear oil seal free and replace it.
8. Remove the hub nut rubber O-ring from the groove in the clutch gear (if applicable).
9. Pull the access cover free with Transmission Access Cover Puller (H-D Part No. 95560-57) or an appropriate sized gear puller

SHIFTER MECHANISM DISASSEMBLY

1. Remove Second gear from the mainshaft, cap screw, retainer ring, and washer. Using snap-ring pliers, remove the cam retaining ring and slide it off the camshaft thrust washer.
2. Remove the gear shifter cam, pawl carrier, pawl carrier support, and pawl carrier support shims (if applicable). Remove the pawl spring and shifter pawls.

NOTE: *On 1972 and later models, remove the retaining rings to free the pawls, spacers, and springs from the pawl carrier. To free the shifter forks and finger rollers, first remove the countershaft assembly.*



3. After removing the lever arm shaft, fork shaft, cam follower retainer ring, follower retainer, and follower spring, the shifter forks and finger rollers should come free.

MAINSHAFT AND COUNTERSHAFT DISASSEMBLY

1. Remove from the right crankcase the mainshaft, thrust washer, and the 23 rollers.
2. Remove First gear from the mainshaft using a claw puller if necessary.
3. Pry the Third gear retainer ring from its groove in the mainshaft and replace it.
4. Remove the Third gear washer and Third gear from the mainshaft.
5. With the access cover on an arbor press, press the clutch gear free from its bearing.
6. Remove the First gear washer and Third gear from the countershaft.
7. With a claw puller, remove the drive gear from the countershaft, and remove the gear spacer, Second gear, and the thrust washer.
8. Remove the countershaft low gear and washer.
9. Drift the oiler plug free from inside the access cover.

TRANSMISSION SPROCKET AND SHIFTER MECHANISM INSPECTION

1. Clean all metal parts in a suitable solvent and blow dry.
2. Inspect the mainshaft sprocket for worn or damaged teeth and splines; replace if necessary. Replace the oil seal and gasket if necessary.
3. Replace the gear shifter cam retaining ring. Inspect the shifter cam for worn or grooved thrust points which cause irregular shifting and replace if necessary.
4. Inspect the shifter pawl carrier for grooves or wear at the fingers. Inspect the pawl carrier support for breaks or cracks.
5. Check the bearing for excessive play by loosely assembling the shifter cam, pawl carrier, support, and shims (if applicable). Replace any worn or pitted parts.
6. Replace the pawl carrier springs with 16-coil cadmium plated springs, or fourteen to sixteen coil black phosphatized springs. Spring free-length should be $2^{25}/_{32}$ in. when new.
7. Check pawl spring operation (1970–71 models) by inserting the springs in the carrier holes. Spring free-length should be $1^{7}/_{32}$ in. when new. Replace any worn, grooved, or cracked parts. On 1972 and later models, check pawl and carrier. Free length of spring is 1¾ in.
8. Inspect the finger rollers and shifter forks for warping, wear, or grooves.
9. Check the shifter cam follower and spring for freedom of movement and replace if worn. Free-length of a new spring should be $1^{19}/_{32}$ in.
10. Remove the shifter fork shaft only if it is to be replaced. The shaft is press-fit and aligned at the factory, and therefore should be replaced together with a new cover. Check the shaft for warping or damage by observing shifter fork movement on the shaft. The shaft may only be replaced by pressing out the old and pressing in the new, taking care to keep it perpendicular to the cover face.

8. Mainshaft third gear
9. Access cover
10. Clutch gear
11. Countershaft low gear washer
12. Countershaft third gear
13. Countershaft drive gear
14. Countershaft geor spacer
15. Countershaft second gear
16. Countershaft second gear thrust washer
17. Transmission countershaft
18. Countershaft low gear
19. Countershaft low gear washer (variable thickness)
20. Mainshaft ball bearing
21. Mainshaft ball bearing snap ring (2)
22. Countershaft oiler plug
23. Countershaft low gear bushing
24. Clutch gear oil seal (1970 only)
25. Clutch hub nut O-ring (1970 only)
26. Clutch gear oil seal extension (1970 only)
27. Clutch gear bushing
28. Clutch gear needle roller bearing
29. Mainshaft thrust washer
30. Mainshaft roller bearing race
31. Mainshaft roller bearing retainer ring
32. Mainshaft roller bearing washer
33. Countershaft bearing—closed end
34. Countershaft bearing—open end

11. Inspect the gear shifter lever arm for warping or damage.
12. Check the bushings for excessive play by inserting and rotating the shaft. Bushings must be pressed in with the gearcase cover and oil seal removed. Drift from the right-side. Remove any high spots with a ½ in. reamer and replace the oil seal.

MAINSHAFT AND COUNTERSHAFT INSPECTION

1. Clean all metal parts in a suitable solvent and blow them dry.
2. Inspect, and replace if necessary, all gears, pinions, and dogs for a worn, chipped, or otherwise damaged condition—especially if the transmission frequently jumped out of gear.
3. Inspect the mainshaft and countershaft for excessive wear on the splines and bearing surfaces, and replace if necessary.
4. Slip the gears into position on their shafts and check for excessive play and replace if necessary. Specifications are listed in the "Transmission Specifications" chart.
5. The low gear bushing is a press-fit. If replaced, check for high spots and ream it until round.
6. Remove the clutch gear oil seal extension with cloth or leather-covered vise grips in order to remove the clutch gear bushing and needle roller bearing.
7. Drift out the clutch gear bushing and drift out the needle roller bearing and thrust washer from the opposite end of the gear.
8. Press a new bushing into the clutch gear shaft, insert the mainshaft and rotate the gear to check for high spots and free-movement. If there is not 0.001–0.002 in. play, ream the bushing to size (H-D Reamer, Part No. 94829-42).
9. Press on the printed side of the needle roller bearing to install the bearing and thrust washer.
10. Seal the oil extension with aluminum paint.
11. Install a new oil seal and O-ring.
12. Test the main shaft and countershaft for alignment with a dial indicator and replace if warped 0.003 in. or more.
13. Check the play between the mainshaft ball bearing, clutch gear, and access cover. Replace if play exceeds specifications listed in "Transmission Specifications."
14. Remove the mainshaft ball bearing snap-ring and press the bearing free on an arbor press from the outside in. If the bearing is drifted out, it should be replaced.
15. Inspect the mainshaft rollers and bearing race and replace if pitted, scored, or worn beyond specifications. Pack with grease before assembly.
16. Remove the race by removing the retaining ring and washer. Heat the case around the bearing and drift from the outside in. Press in a new race until its shoulder seats. Check clearances against those listed in "Transmission Specifications" and replace if necessary. Replace the snap-ring.
17. Check the countershaft needle roller bearings against the proper specifications listed in "Transmission Specifications." Drift free only if replacement is necessary, pressing on the printed side.

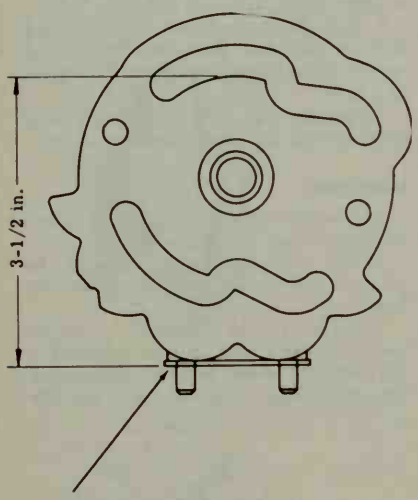
The access cover must be 5/64 in. from the side.

18. Replace the oiler plug after the shaft clearances are established and replace with the oil hole up.

TRANSMISSION ASSEMBLY

1. Install the cam follower retainer ring and retainer in the access cover.

2. Seat the pawl carrier springs against the pawl carrier support.



1970–71:

3. Assemble the shifter pawls and springs in their respective sockets with the top engaging grooves facing one another.

4. Depress the pawls with a knife blade and assemble the cam, carrier, support, and shims (if applicable).

5. Install the camshaft thrust washer and a new retaining ring, using snap-ring pliers.

6. Depress one pawl at a time with a knife blade and rotate the shifter cam to ensure free cam movement.

Shimming dimensions for pawl carrier support: rotate cam to 3rd gear position and shim as required using a quantity of 0.010 in. thick shims as necessary to obtain a 3½ in. dimension to the cam surface as shown.

7. Use shims to adjust the height of the cam as shown to ensure proper shifter fork operation.

1972 and later models: Assemble the pawls on the carrier using spacers (one on outside, one underneath) to align the spring hooks and holes. Secure the pawl retaining ring and spring. Depress one pawl at a time while inserting the shifter cam in the pawl carrier. Assemble the carrier into the support so that the carrier ear seats between the springs.

8. Arbor-press the clutch gear into the mainshaft bearing.

9. Assemble the Second gear thrust washer, Second gear, Second gear spacer, and the drive gear on the countershaft, making sure that Second gear rotates freely. Install the assembly in the access cover.

10. Install the mainshaft second gear, countershaft third gear, and shifter forks on the fork shaft with the finger studs pointed toward the access cover and the fork finger in the running groove of the gear. Install the finger rollers.

11. Install the cam follower and follower spring in the follower retainer. Check to make sure that the follower is free in the retainer.

12. Secure the shifting assembly to the access cover with the capscrew and retainer ring while engaging the shifter fork finger rollers in the shifter cam slots.

13. Assemble First gear, Third gear, the Third gear washer, and a new retainer ring on the mainshaft. The ring is easily inserted with Retainer Ring Sleeve (H-D Part No. 96396-52), but snap-ring pliers will also work.

14. Slide Second gear and the clutch gear onto the mainshaft.

15. Place the thinnest, First gear, variable washer against the countershaft shoulder.

16. Slide First gear on the shaft and check the clearance between the faces of it and Third gear. Try different First gear washers until a clearance of 0.038–0.058 in. is obtained. (Washers are available in thicknesses of 0.065, 0.075, 0.085, and 0.100 in.).

17. Assemble all parts to the access cover except for the mainshaft thrust washer, countershaft first gear washer, mainshaft rollers, roller bearing washer, and bearing retainer ring. Shift through the gears several times to ensure proper operation. With the transmission in Neutral, check to see if gear face clearances are between 0.038–0.058 in. Replace the shifter forks if clearance is not obtained.

Mainshaft and Countershaft End-Play

1. Install the thinnest First gear and Third gear variable washers. Temporarily secure the Third gear washer with a dab of heavy grease, with the ear pointing down.

2. With all parts assembled, install the access cover on the crankcase. Take care to align the dowel pins, tap the cover into place with a soft mallet, and secure it with the cover cap screws.

3. Check mainshaft end-play with a dial indicator from the sprocket side of the shaft by shifting the shaft back and forth. Repeat on the countershaft from the access cover side.

4. Wedge a discarded wheel spoke, or something similar, in the countershaft end hole and measure end-play while pulling and pushing on the spoke.

5. End-play for both shafts must be within 0.003–0.009 in. Adjust by installing larger mainshaft thrust and countershaft First gear washers. Washers are available in 0.005 in. gradations from 0.050–0.075 in., and countershaft washers of 0.020, 0.030, and 0.040 in. are also available.

6. Center the lever arm shaft so it will engage the pawl carrier support when the cover is in place. Lightly rotate the shaft to ensure correct engagement before securing the cover.

7. Grease the mainshaft bearing race and assemble the rollers. Secure the roller with the bearing washer and retaining ring.

Mainshaft Sprocket, Starter, and Clutch Assembly Installation

1. Temporarily install the foot-shift lever and place the transmission in Fourth gear.

2. Install the oil seal gasket, seal, retainer, lockwashers, and screws, but do not secure them yet.

3. Temporarily place the sprocket on the mainshaft to correctly position the retainer.

4. Remove the sprocket and secure the screws.

5. Assemble the sprocket, lockwasher, and nut. Secure the washer ear against the nut.

6. Install the rod end and drive chain.

7. Consult the "Starter" section for starter installation procedures.

8. Consult the "Clutch" section for clutch installation procedures.

9. Lubricate the transmission as described in the following section.

Transmission Lubrication

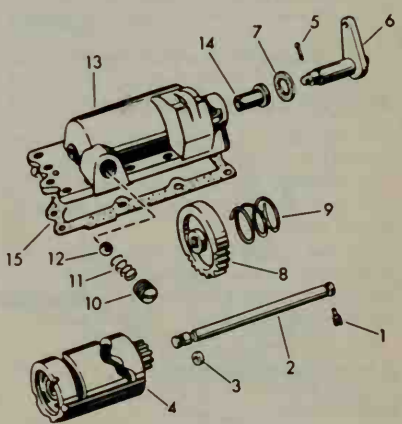
1. Stand the motorcycle upright and remove the oil filler plug from the chaincase top and the oil level plug from the chaincase bottom.

2. Fill the transmission with engine oil until the overflow begins from the oil level plug hole.

3. Secure both plugs when overflow ceases.

Glide Models

LINKAGE ADJUSTMENT



Hand Shift

Adjust the hand shift if the transmission is moved.

1. Place the transmission in Third gear on four-speed models, and Second gear on three-speed models.

2. Disconnect the shifter rod at the shifter lever.

3. Gently shift the lever back and forth until you feel the spring plunger reach its seat.

15. Cover gasket

4. Adjust the clevis until the rod can be attached without moving the lever.

Foot Shift

Adjust the shifter rod when the transmission is moved if wear necessitates adjustment.

1. Align the shift lever clamping slot with the foot lever shaft notch (FL only).
2. Disconnect the lever from the rod and adjust the rod end as desired. Secure the locknut and connect the rod and lever (FL, FX to 1973).
3. FX, 1974 and later: remove the retainer clip and adjust the threaded ends on rod.

TRANSMISSION REMOVAL

1. Disconnect the battery ground wire from the negative terminal.
2. Remove the footrest, chain cover compensating sprocket (if applicable, consult "Clutch" section), or shaft nut (nut is removed by striking a 1⅝ in. wrench with a hammer).
3. Remove the chain adjuster mounting bolt and the starter shaft thrust washer (1965 model only).
4. Remove the clutch, clutch hub, drive sprocket, and primary chain as described in the "Clutch" section.
5. Loosen the five transmission mounting bolts and remove the chainguard and oiler.
6. Remove the starter solenoid terminal wires.
7. Remove the battery, carrier, and regulator ground strap from the right-side of the transmission. Remove the right rear footrest bracket.
8. Remove the starter motor bracket and pull the starter motor out of the left-side of the frame. Remove the kick-starter lever (if applicable).
9. Loosen the locknut at the clutch foot control or booster, and turn the rod out until it can be slid free of the clutch release lever.
10. Remove the shifter rod.
11. Disconnect the speedometer cable and housing from the transmission.
12. Remove the Neutral indicator switch.
13. Remove the transmission as a unit.

SHIFTER COVER REMOVAL

1. Remove the transmission as described in "Transmission Removal."
2. Remove the twelve securing screws and pull the cover free from the two dowel pins.
3. The screw for the hole nearest the dowel pin on the right side of the transmission is vented and must be installed in the same location.

HAND SHIFTER COVER

Disassembly

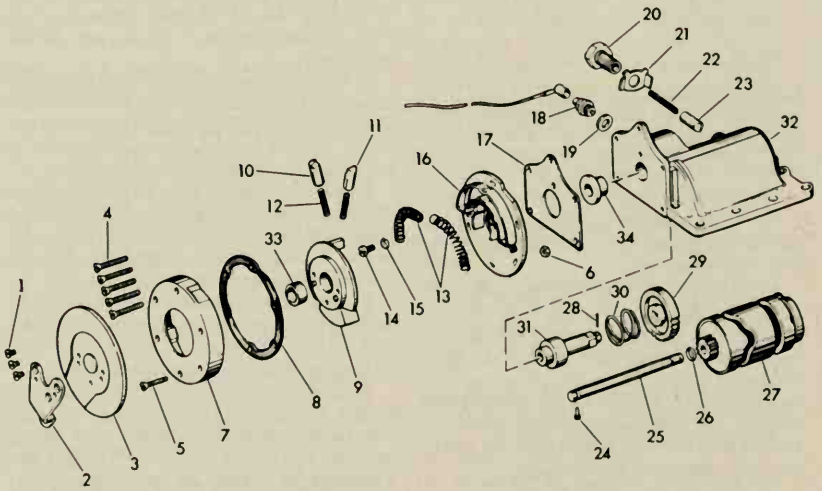
1. Remove the shaft lockscrew and drift the shaft free with a discarded valve stem or something similar.
2. Remove the shifter cam.
3. Remove the shifter lever cotter pin.
4. Pry the shifter gear from the shaft by tapping a screwdriver between the gear and the inside of the cover.
5. Remove the shifter lever and leather washer.
6. Remove the cam plunger capscrew, ball spring, and plunger ball.

Inspection

1. Clean all metal parts in a suitable solvent and blow them dry.
2. Inspect the shifter lever bushing for excessive wear—indicated by excessive lever play—and replace if necessary. Screw a ⅝ in. tap into the bushing. Remove the tap and heat the case to about 300 degrees. Screw in the tap, clamp it in a vise, and tap the cover with a soft mallet until the cover comes free.
3. Inspect the teeth on the shifter gear and cam pinion for wear or damage and replace if necessary.
4. Inspect the plunger ball seat and cam track for excessive wear and replace if the edges are not sharp.
5. The oil seal and cover gasket should be replaced but may be used again if in good condition.

Assembly

1. Hold the shifter gear spring in place inside the cover and place the shifter gear on it so the gear hub is inside the spring. The gear must have the timing mark on the gear tooth facing the shift lever cover port.
2. Slip the leather washer onto the shifter lever and insert the lever through the case and spring so that it meshes with the shifter gear. The lever should be pointed toward the left.
3. Secure the assembly with the lever shaft cotter pin.
4. Insert the cam in the cover so that the pinion gear timing mark aligns with the shift gear mark.
5. Place the oil seal on the camshaft and insert it through the case and cam. Secure it with the shaft lock screw.
6. If cam end-play is greater than 0.0005–0.0065 in., install shims as necessary. If play is too little the cover can be filed as necessary.



FOOT SHIFTER COVER

Disassembly

1. Remove the shifter lever screws, lever, dust shield, and long cover screws.
2. Remove the short cover screw nut from the back of the adaptor plate, withdraw the short cover screw, and remove the pawl carrier cover, gasket, pawl carrier, pawls, pawl springs, and pawl carrier springs.
3. Remove the adaptor plate bracket screw, washer, adaptor plate, and plate gasket.
4. Disconnect the neutral indicator switch from the cover.
5. Bend back the cam follower retainer washer ear to remove the retainer, washer spring, and cam follower.
6. Remove the camshaft lockscrew and drift the camshaft from the cover, using an old valve stem, or something similar, as a drift.
7. Remove the shifter shaft cotter pin, gear, spring, and shaft from the cover.

Inspection

1. Consult "Hand Shift Shifter Cover Inspection and Replacement."
2. The Neutral switch should be cleaned only with Gunk® or similar solvent.
3. Depress the neutral indicator switch plunger and observe whether or not it returns freely. If the plunger binds, the panel lamp will not light and the

switch must be replaced. Do not run current through it without the panel lamp neutral indicator in series so the circuit is completed.

4. If the pawl carrier hole has been worn until it is oversized, replace the press-fit pawl carrier bushing.

Assembly

1. Hold the shifter gear spring in the cover and place the shifter gear on it so the gear hub is inside the spring. The gear tooth timing mark must face the cover.

2. Slide the shifter shaft through the cover until it meshes with the gear. The timing mark should be in line with the squared side of the shaft and slightly to the left of the last ratchet tooth on the shaft.

Alignment of shifter gear timing marks

3. Gently tap the shaft and gear together; secure them with the shaft cotter pin.

4. Place the oil seal on the wider of the two camshaft end grooves.

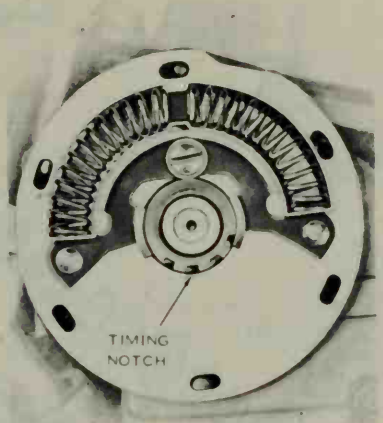
5. Place the shifter cam in the cover and hold it in position where the cam pinion timing mark aligns with the shifter gear timing mark.

6. Secure the cam with the camshaft and secure the camshaft with the lockscrew.

7. Slip in the cam follower and spring and secure them with the retaining washer and retainer.

8. Secure the neutral indicator switch and check to make sure that the plunger contacts the shifter gear.

9. Secure the cover in a vise with the shifter mechanism end pointing up.



10. Place the adaptor plate gasket on the case.

11. Attach the cover screw nut to the back of the adaptor plate with a dab of heavy grease and place the adaptor plate on the gasket.

12. Loosely screw the adaptor plate bracket screw and washer into the hole above the end of the shifter gear.

13. Place the gearshift cam in any gear, other than Neutral, and rock the cam back and forth to be sure that the cam follower is seating properly in one of the indexing notches.

14. Rotate the adaptor plate until the

Aligning shifter adaptor plate timing marks

plate timing notch lines up between the two bottom teeth of the shifter gear. Secure it with the adaptor plate bracket screw.

15. Lightly grease the pawl carrier springs and place them in the slots on the adaptor plate.

16. Lightly oil the pawls and check to see that they move freely in the pawl carrier holes.

17. Install the pawl springs and pawls so that the end face notches face each other.

18. Place the pawl carriers on the shifter shaft so that the carrier lug seats between the pawl carrier springs.

19. Lubricate the pawl carrier back.

20. Assemble the cover gasket and cover. Apply Locktite® (H-D Part No. 99619-60) or a suitable thread-sealing compound to the cover screws and insert them. The short screw should seat in the cover screw nut. Secure all screws.

21. Place the dust shield over the pawl carrier dowel pins and set the shifter lever over the dust shield dowl pins. Secure it with the shift lever screws.

Installation

1. Apply sealer to the shifter cover and secure it to the gearbox.

2. Place the assembled shifter cover over the gearbox and secure it with the twelve securing screws. The two longer screws go in holes near the bulge over the shifter gear. The vented screw goes nearest the locating dowel pin on the gearcase right side. Apply a thread sealer to all but the vented screw.

SHIFTER FORK

Removal

1. Remove the shifter cover as described in "Shifter Cover Removal."

2. Disassembly is not necessary if the shifter fork assemblies are not damaged or worn and shifter clutches are not to be replaced.

3. Remove the shaft lockscrew and drift out the shaft.

4. Separate the shifter fork assemblies upon removal; do not mix parts during replacement.

Disassembly

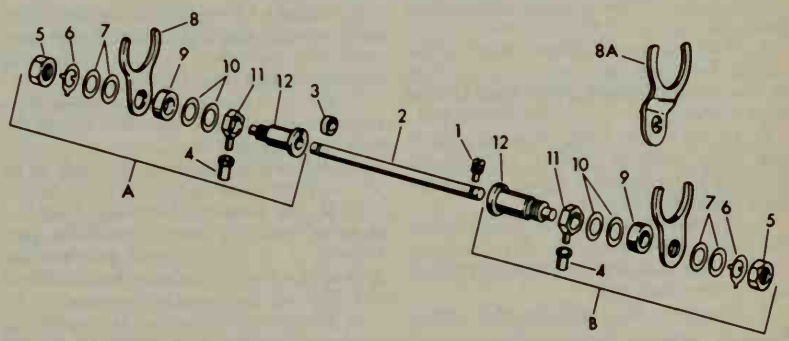
1. Remove the finger rollers.

2. Free the bushing nuts by bending back the washer ears and remove both nuts and washers.

3. Remove the remaining parts, taking note of their positions as an aid in assembly.

Inspection

1. Clean all metal parts in a suitable solvent and blow them dry.



2. Replace bent or worn forks. Do not use forks which have been bent and then straightened.

3. Check the shifter fork bushings for excessive play and replace if necessary. Check new bushings on the shaft and determine if the shaft bushing contact surface is worn.

4. If the bushings bind, they can be lapped by coating the shaft with valve-grinding compound and then spinning the valve in the bushing until movement is free. Clean both parts again thoroughly.

Assembly

1. Assemble in reverse order of disassembly, taking care not to mix any parts. If parts are mixed, it would be better to

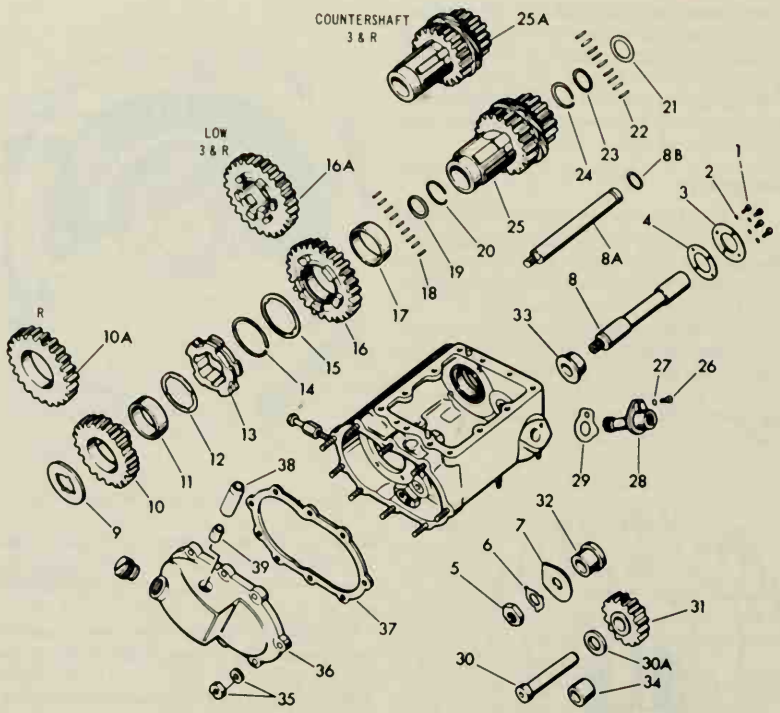
2. Place Fork Shifter Gauge (H-D Part No. 96384-39) on the shifter cover. Align the tool gauge blocks with the straight cam slots by laying the ⅜ in. gauge rod through both. Secure the blocks with thumb screws.

3. Place the tool on the transmission case so that the shifter finger rollers engage the tool slots.

4. Check that the shifting clutches are centered by inserting a thickness gauge on both sides of the clutch.

5. Increase or decrease the number of variable shims, (0.014 or 0.007 in. shims are available), between the fork and finger to center the clutches.

6. First and Second gears should have 0.080–0.090 in. clearance on both sides.



7. Third and Fourth gears should have 0.100 in. clearance on both sides.

8. Reverse gear should have 0.060–0.070 in clearance between gear teeth.

9. If the gears have engaging dogs, rotate the gears so that the dogs on the gear and clutch overlap by about ⅛ in. before checking clearance.

10. Secure the shaft nut with a thread-sealing compound. Avoid overtightening.

11. Install the forks in the gearbox and secure them with the shaft. The narrowest fork is for the high gear shifter clutch. Secure the shaft lock screw. Install the shifter cover as described in "Shifter Cover Replacement."

FOUR-SPEED GEARBOX DISASSEMBLY

1. Remove the transmission as described in the "Transmission Removal" section.

2. Remove the clutch.

3. Remove the starter assembly.

4. Remove the shifter cover and shifting forks as described in "Shifter Cover Removal" and "Shifter Fork Removal" sections.

Countershaft Disassembly

1. Bend the lockwasher ear away from the countershaft nut and remove both.

2. Drift the countershaft out of the case from left to right.

3. Remove First gear, the First gear bushing, First gear bearing washer, and shifter clutch off the splined countershaft gear.

4. With snap-ring pliers, remove the spring lockring, gear retaining washer, countershaft, Second gear, and Second gear bushing.

5. Remove the roller bearing rollers and roller retainer washer. Do not mix the roller sets; replace entire sets rather than individual rollers.

6. Pry the lockring free and remove the roller thrust washer, rollers, retainer washer, and lockring from the gear end of the countershaft gear.

7. Remove the speedometer drive housing screw, washer, speedometer drive unit, and drive unit gasket.

8. Remove the idler gear shaft, spacer washer, and idler gear on three-speed and reverse-type transmissions. Inserting a ¼–20 tap screw into the shaft will provide a grip for pulling the shaft free. Apply 300° of heat to the case if the shaft will not move.

Mainshaft Disassembly

1. Remove the bearing housing retaining screws, oil deflector, and retaining plate.

2. Using a soft mallet, drive the mainshaft toward the right side of the case, until the mainshaft bearing or bearing housing is free from the case.

3. Pry the mainshaft second gear lockring free of its groove and slide it onto the mainshaft splines.

4. Pull the assembled mainshaft as far as it will go to its right.

5. If the bearing housing does not come off with the bearing, slide the gear through it as far as it will go, clear the gear of the case, and drive the mainshaft out. This should free the housing.

6. Remove Third gear, the retaining washer, lockring, and shifter clutch off the mainshaft and lift them out of the case.

7. Remove the mainshaft through the right-side of the case.

8. If repair is necessary, disassemble the mainshaft gear and bearing assembly.

9. Secure the mainshaft in a copper or wood-jawed vise. Bend the lockwasher ear away from the shaft nut and remove both. Pull the bearing and then the gear from the shaft with a claw puller (H-D Part No. 95635-46) or press them off. Protect the shaft end if a puller is to be used (with H-D Part No. 95636-46).

MAIN DRIVE GEAR

Disassembly

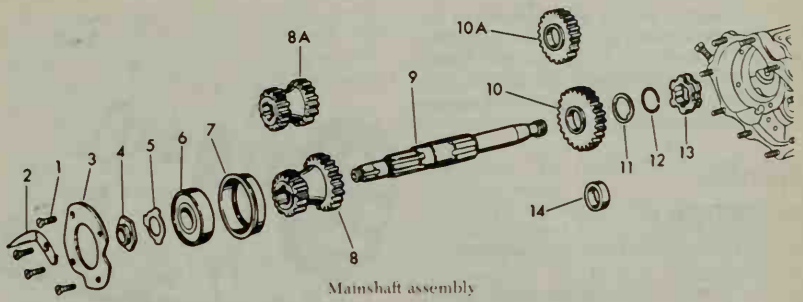
1. Secure the gearbox in a vise or to a work bench. Secure the chain sprocket by laying a length of chain over its teeth and nailing the chain ends to the bench.

2. Bend back the washer ear and remove the locknut (which has a left-hand thread) and washer.

3. Remove the oil deflector and chain sprocket.

4. Push the main drive gear into the case and lift it and the thrust washer out.

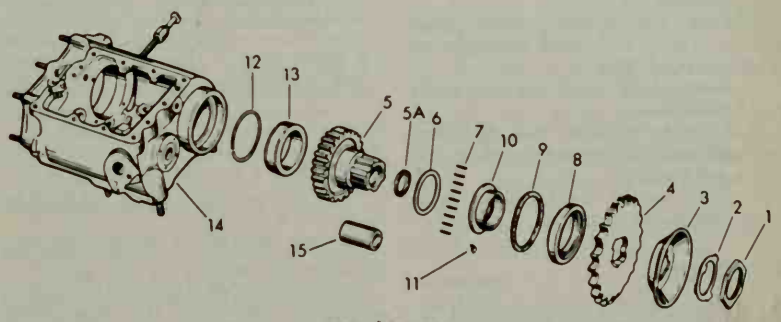
5. Remove the 44 rollers and place them where no mix-ups or lost bearings will occur. Bearings must be replaced as an entire set.



6. Remove the drive gear oil seal, shaft seal, or main drive gear spacer only if worn or damaged.

Inspection

1. Clean all metal parts in a suitable solvent and blow them dry.
2. Inspect all of the gears for damage to the teeth or case hardening and replace if necesssary.
3. Inspect all bushings, bearings, and shafts for wear and excessive play; replace if necessary.
4. The main drive gear bearing race can be pressed in and out. Heating the case to about 300 degrees will facilitate removal. Press a new bearing in until the flange seats on the case. Replace the race retaining ring.
5. Replace the cork washers and oil seals. Apply sealer to the gear end recess when replacing the shaft seal.
6. Replace the shifter clutches and gear engaging dogs for wear or damage, and replace if necessary. Edges should be sharp rather than rounded.
7. Check bearings for smooth operation and proper fit in their races. Specifications are listed in the "Transmission Specifications" chart. Rollers are available in 0.0004 and 0.0008 in. oversizes and must be replaced as a set.



Assembly

1. Assemble the main drive gear oil seal, cork washer, and gear spacer in the case.
2. Install and grease the bearing race and install the rollers.
3. Assemble the main drive gear thrust washer on the main drive gear and slip the gear into the bearing race, taking care not to displace any rollers.
4. Install the main drive gear spacer key in its slot in the outer edge of the gear spacer, with the long section in any gear splineway.
5. Slip the sprocket, with the flat side away from the case, onto the gear splines. Assemble the oil deflector and lockwasher; secure the locknut.
6. Using a dial indicator, check endplay as listed in the "Transmission Specifications" chart.

MAINSHAFT ASSEMBLY

1. Assemble First and Second (or First and Reverse gear depending on the model) gears on the splines, mainshaft bearing housing, bearing, bearing washer, and the bearing nut to the mainshaft.
2. Press the bearing housing over the mainshaft ball bearing, press onto the shaft, and secure with the lockwasher and nut. Bend the washer ear against the nut.
3. Insert the shaft into the gearbox and install the mainshaft Third gear (Second gear on three-speed models), thrust washer, lockring and shifter clutch with the "high" side facing the drive gear.
4. Seat the lockring in its groove on the shaft.
5. Gently tap the shaft assembly into the case with a soft metal hammer or brass drift until the bearing housing flange seats against the case.
6. Install the Reverse idler gear on three-speed models.
7. Assemble and secure the retaining plate, oil deflector, and retaining plate screws.

COUNTERSHAFT ASSEMBLY

1. Insert the lockrings and bearing retainer washers in the countershaft gear.
2. Apply grease to the inside of the countershaft gear and assemble both roller sets.
3. Install the bearing thrust washer in the gear end.
4. Temporarily install the shaft to check bearing end-play and motion. Consult the "Transmission Specifications" chart for necessary information.
5. Apply a dab of heavy grease to the gear end washer and mount it, and the gear, in the case.
6. Check gear end-play by inserting a thickness gauge between the gear and washer. Consult the "Transmission Specifications" chart for proper clearance and adjust with the appropriate number of washers. (0.074, 0.078, 0.082, 0.085, 0.090, 0.095, and 0.100 in. washers are available.) When the correct amount of washers is arrived at, set aside the shaft, gear, and gear end washer.
7. Assemble the Second gear bushing, gear, thrust washer, and gear lockring on the countershaft gear.
8. Assemble the shifter clutch, thrust washer, first gear bushing, and gear on the countershaft gear.
9. Apply a dab of heavy grease to the countershaft gear end washer and place it on end of the gear.
10. Hold the assembly in the case and insert the countershaft. Secure the bearing lockwasher and nut, and bend up an ear of the washer.
11. Install the drive unit gasket, drive unit, washer, and screw.

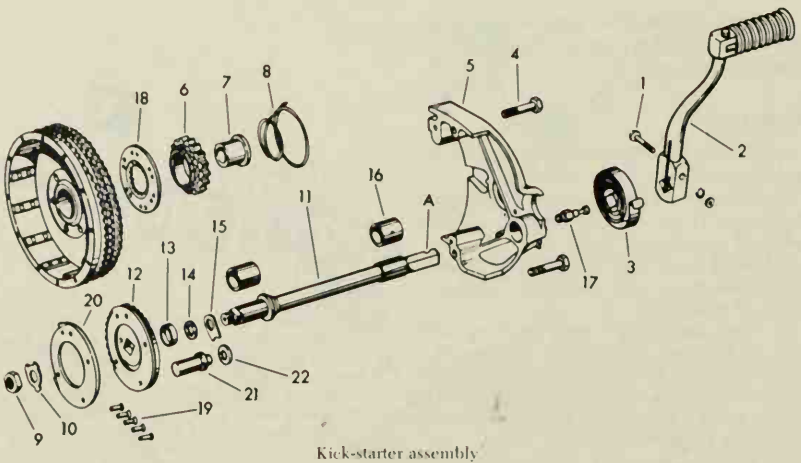
THREE-SPEED GEARBOX DISASSEMBLY

Procedures are basically the same as outlined for the four-speed box. Refer to the illustrations for parts differences in three-speed.

STARTERS

Clicking noises from the starter gears are an indication of trouble. This will occur with the engine running and the starter crank in its proper position, and is caused by the starter clutch teeth. Tightening down the starter shaft nut on the crank gear camplate will often solve the problem.

Slipping, or partial engagement of the starter crank during its cycle, indicates either broken or worn starter clutch teeth, a damaged clutch spring, sticking of the clutch gear on the sprocket spacer, or a worn brass fitting.



Sportster

DISASSEMBLY

1. Loosen the front cylinder and exhaust pipe.
2. Remove the starter crank clamp bolt and pry the crank free of the shaft.
3. Apply pressure to the end of the starter spring and pry it free of the shaft.
4. Remove the sprocket cover bolts and lightly tap off the cover with a soft mallet while pulling it from the shaft.
5. Push the clutch lever forward and disengage the cable.
6. Remove the clutch.
7. Free the starter clutch gear, sprocket spacer, and clutch spring by rotating the crank gear.
8. Remove the shaft nut and crank gear lockwasher.
9. Loosen the starter crankshaft from the crank gear by tapping the shaft end with a soft mallet.
10. Slide out the crankshaft, oil seal, shims, and thrust plate.

INSPECTION

1. Clean all parts with a suitable solvent, except for the cover gasket if it is to be reused, and blow them dry.
2. Inspect the starter clutch and starter clutch gear for worn or damaged teeth, and replace if necessary.
3. Spin the clutch gear on the spacer and check for binding. Replace any damaged parts.
4. Replace the starter clutch spring if the length is under 1 in., in a free state, or if it is extremely fatigued.
5. Check the starter crankshaft for distortion. Check for excessive wear on the surfaces of the bearing and on the faces of the thrust washer and shaft collar. Replace if necessary.
6. Temporarily mount the following assembly in the left crankcase: crankshaft, oil seal, thrust plate, crank gear, lockwasher, and shaft nut, checking all parts for wear and replacing as necessary.
7. Spin the shaft and measure for excessive end-play with a dial indicator. End-play must be within 0.001–0.007 in. Shims which are 0.007 in. thick are available (H-D Part No. 6802).
8. Inspect the starter crank gear for wear or damage, especially to the ears. The camplate can be replaced independently of the crank gear.
10. Check to make sure that the camplate rivets are all secure.
11. Replace the bushings if excessive end-play is present but the shaft is not worn. Press the old bushing out and the new one in taking care to align the bushing hole with the grease-fitting channel.
12. Only inspect or replace the gear stop pin and washer if the engine is not in the chassis. These parts rarely need service. The pin is a press fit and the washer is secured by peening the pin end.

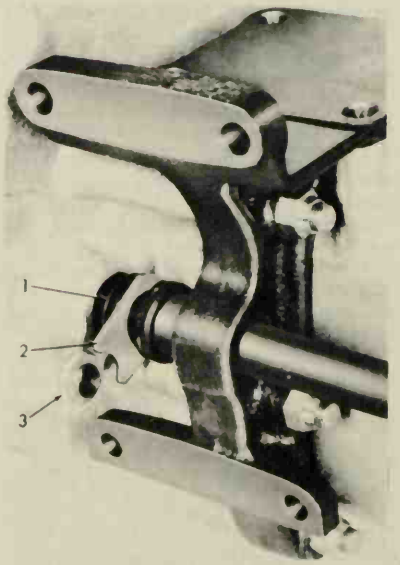
ASSEMBLY

1. Insert the oil seal into the crankcase.
2. Slide the thrust washer onto the countershaft with the flat side up.
3. Assemble the shim on the shaft (if applicable) and insert the shaft in the crankcase so that the thrust washer notch lines up with the stop pin.
4. Rotate the crank until the notch on the outer end of the shaft is pointing up.
5. Place the starter gear on the shaft end with the recessed portion of the camplate facing down. The slot should seat against the stop pin. Check to make sure that the thrust washer has not shifted out of place.
6. Install the lockwasher over the shaft so that its prong engages the hole in the crank gear face, and secure it with the flat side of the shaft nut against the washer.
7. Slip the spacer into the starter gear so that the grooved side of the gear bushing seats on the spacer lip.
8. Align the clutch spring small end in the gear bushing groove.
9. Press the starter gear into mesh with the starter clutch, and rotate the crank gear so that the clutch gear and crank gear also mesh. The spring will hold the assembly in place once the cover is installed.
10. Rotate the crank gear to its original position. By taking a strip of metal and drilling holes to match the cover screw securing holes, the strip can be mounted to temporarily hold the spring in position until the cover is mounted.
11. When replacing a sprocket spacer, make sure that you use one of the same length. If new gears are used, the clearance between the teeth must be checked in the following manner:



a. Measure the distance from the spacer collar to the top of the clutch gear teeth.

b. Measure the distance from the top of the clutch gear teeth to the sprocket washer.

c. Subtract the answer of "b" from that of "a" to get the proper clearance.

d. Use a long spacer if the result is less than 0.040 in. after a small spacer has already been used.

12. Install the clutch.
13. Secure the clutch cable end in the release lever, and mount and secure the sprocket cover, exhaust pipe, and muffler.
14. Place the crank spring on the shaft end with the spring end pointing upward. Secure the spring on the spring stud by prying with a screwdriver.
15. Mount and secure the starter crank.

Starter crankshaft installation

1. Starter crankshaft shim—0.007 in.

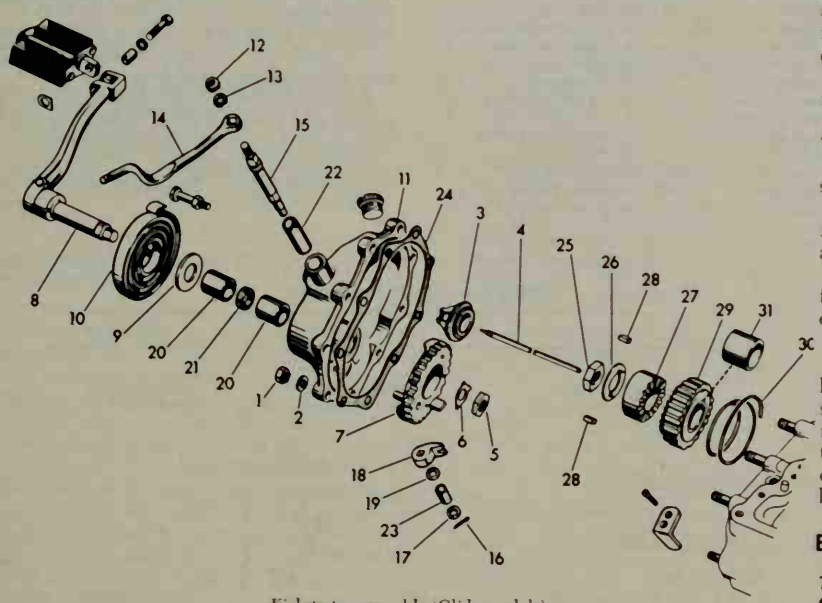
Glide Models

DISASSEMBLY



1. Place a drip pan under the transmission.
2. Remove the clutch lever rod from the release lever, cover nuts and washers, and pull the cover and release lever assembly free from the mounting studs.
3. The clutch release bearing should come off with the cover, but may bind on the starter clutch. Do not attempt to pry it from the cover, but it may be pried free from the clutch.
4. Pull the pushrod free of the mainshaft.
5. Secure the crank with a vise or vise grips which are blocked against movement.
6. Bend the lockwasher ear from the crank nut and remove both the nut and the washer.
7. Pull the starter gear with a claw puller or remove the vise and drive the crank free with a soft mallet. Block the crank and cover against swinging when the shaft is free from the gear.
8. Pull the crank out of the cover and the crank spring, thrust washer, crank bushings, and oil seal will all come free.
9. Remove the release lever nut and lockwasher, and pull the release lever free with a claw puller.
10. Remove the release finger and thrust washer by removing the cotter pin and washer; pull the shaft free.

INSPECTION

1. Clean all parts with a suitable solvent and blow them dry.
2. Check play between the starter crankshaft and the cover bushing, and replace if play is excessive. Press new bushings in until they are flush with the outer surface.
3. Replace the oil seal if the transmission was leaking through the starter crank.
4. Check for play in the release lever shaft. Replace the shaft if play is excessive.
5. Inspect the pushrod bearing for wear and replace it if the action is not smooth or is excessively loose.
6. Inspect the crank gear camplate and gear pin for wear. This is all assembled on the starter crank gear and is probably worn if the bushings were worn.

ASSEMBLY

1. Assemble the release lever shaft, lever bushing, release finger, thrust washer, lever bushing, washer, and cotter pin on the starter cover.
2. Press the crank bushing and oil seal in the cover after lightly greasing the seal.
3. Assemble the crank spring and the thrust washer (with beveled side facing spring), and insert the crank after lightly greasing the shaft.
4. Block the crank with a vise and wind the spring by rotating the cover clockwise.
5. With the crank held in normal position, install the crank gear so that the gear will maintain normal crank position.
6. Secure the crank with the lockwasher and nut, bending the washer ear against a flat side of the nut.
7. Install a new gasket on the case studs after applying gasket sealer or silver spray.
8. Install the clutch release bearing into the cover so that the slot in the bearing race engages the clutch release lever finger.
9. Slide the pushrod's narrow end into the bearing.
10. Slide the cover into place making sure the pushrod enters the main shaft.
11. The starter clutch ball plunger and the groove in the release bearing inner race must be aligned.
12. Secure the cover.
13. Fill the case with 1½ pts of oil of the same viscosity as that used in the engine.

STARTER CLUTCH

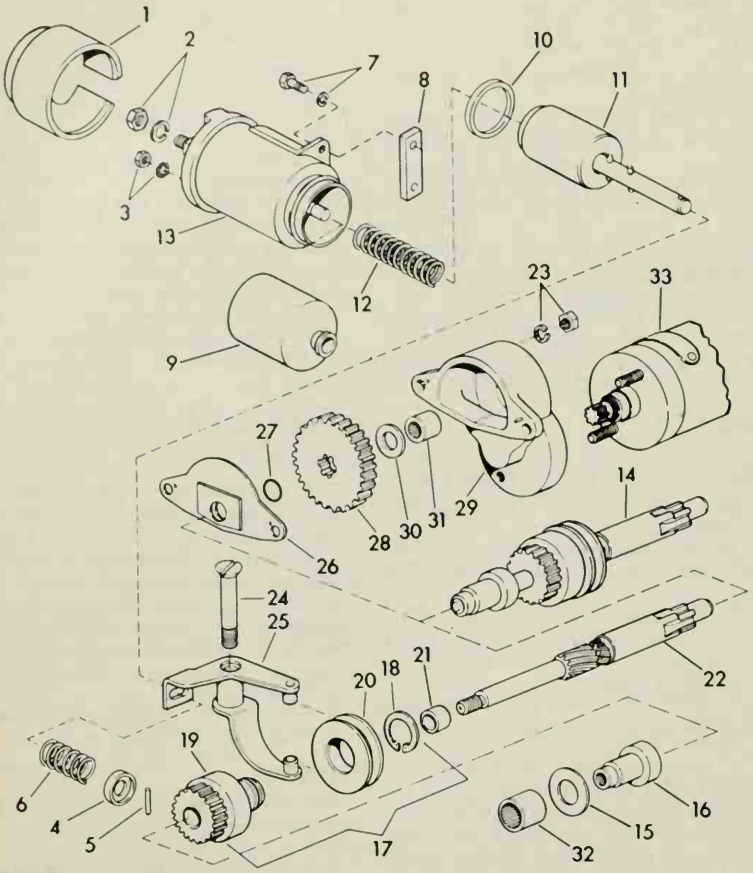
Disassembly

1. Remove the starter clutch cover assembly as described in the "Starter Disassembly" section.
2. Bend the lockwasher ear free of the clutch nut and remove both parts.
3. Pull the starter clutch from the mainshaft with Starter Clutch Puller (H-D Part No. 95650-42), or a suitable substitute, taking care not to damage the clutch teeth.
4. Remove the starter clutch keys, mainshaft gear, and clutch spring.

Inspection

1. Clean all parts in a suitable solvent and blow them dry, except for the cover gasket if it is to be reused.
2. Inspect the starter clutch, mainshaft gear, starter gear teeth, mainshaft gear, and starter clutch ratchet teeth. Replace if the teeth are rounded, mushroomed, chipped, or cracked.
3. Examine the mainshaft gear bushing and replace if necessary.

Assembly



Assemble in reverse order of disassembly. Note the following:

1. Replace the gasket if possible. Apply sealer to the case side of the gasket and position it on the case.
2. Rotate the mainshaft gear to ensure free motion and ream the bushing if necessary.
3. Drive the keys into the slots.
4. Secure the starter clutch nut and bend the lockwasher ear against a nut flat side. The top of the starter clutch must never be less than ⅝ in. above edge of the gearbox. If overtightened, the starter clutch may crack, causing damage to the bearing.

Electric Starter Drive

1966 AND LATER SPORTSTER, AND GLIDE MODELS

Harley-Davidson uses a Bendix-type drive assembly. When the starter button is depressed, the solenoid withdraws its plunger, causing the pinion shifter lever to pivot on its base. The arm of the lever rides in the shifter collar and the pivoting action causes the pinion gear to move along the shaft. Rather than a worm sleeve, the shaft itself has special threads

which are constantly meshed with the threads in the pinion gear.

At the same time the plunger is withdrawn, the solenoid completes the starter motor circuit which rotates the starter shaft. When the pinion gear reaches the collar of the starter shaft nut, it stops and engages the clutch gear. The spiral threads allow the pinion gear to back off if it doesn't mesh properly.

When the button is released, the plunger again shifts the lever so the pinion gear resumes its inoperative position and the starter motor circuit is broken. The clutch gear is a one-way clutch which will allow the starter shaft to spin independently of the engine through a ratcheting action. This means that if you don't release the button after the engine starts, no damage will occur to the starter or the starter drive mechanism.

Solenoid and Starter Drive Shaft Disassembly

1. Disconnect the battery ground wire from the negative terminal post.
2. Remove the nuts and lockwashers from the solenoid terminals and disconnect the wires.
3. Remove the drive housing end cover bolts, lockwashers, and end cover.
4. Press on the solenoid shaft pin retainer cup, and remove the shaft retainer pin and the plunger shaft spring.
5. Remove the solenoid securing bolts, lockwashers, spacer bar, and solenoid assembly.
6. Remove the solenoid boot, plunger, and plunger spring.
7. Remove the pinion shifter lever screw and lift the lever free.
8. Remove the starter drive shaft assembly.
9. Place the drive gear in a wood or copper-lined vise and remove the shaft nut. This must be done with rubber or cloth between the jaws of a vise grip, or something similar, so that nut is not marred or distorted. The nut has a left-hand thread.
10. Slip the pinion gear and shifter collar from the shaft.
11. Using snap-ring pliers, remove the shift collar retaining ring and separate the pinion gear from the shifter collar.
12. Slip the spacer from the shaft.
13. Bushings are a press fit and should be removed only if they are to be replaced.

Solenoid Starter Drive Shaft Inspection and Repair

1. Clean all parts in a suitable solvent and blow them dry.
2. Inspect all parts for excessive wear and replace as necessary. Pay special attention to all gear and pinion teeth. Complete assemblies are available as well as individual parts.
3. Check the bushings for excessive play and replace if necessary.
4. Repack the needle bearings with grease and press-fit them until they are flush with the outside of the housing.
5. Replace, if possible, the collar retaining ring if it has been removed.

Solenoid and Starter Drive Shaft Assembly

Assemble in reverse order of disassembly. Note the following:

1. Lightly lubricate the bearings with heavy grease.
2. Secure the shaft nut with a thread-locking sealer.
3. Spin the assembled shaft in the bearings to check for free movement. This will indicate whether or not the shaft nut was distorted during removal.
4. Stake the starter shaft housing washer.
5. Secure the battery cable and two red wires to the solenoid "top" terminal.

LUBRICATION SYSTEMS

OIL PUMP

Sportster and Glide models have both feed-type and scavenger gear-type pumps incorporated in one pump body.

Oil pumps are long-life units which seldom require repair. Therefore, one should check all related possibilities which might contribute to a "light-on" or "no-pressure" situation before disassembling the pump.

Sportster

OIL PUMP CHECK VALVE DISASSEMBLY

1. Clean the pump surface and its surrounding area thoroughly with a suitable solvent and blow it dry.
2. Disconnect the oil pressure switch wire and remove the switch, oil pump nipple, check valve spring, and ball valve.

OIL PUMP CHECK VALVE INSPECTION

1. Clean all parts in a suitable solvent and blow them dry. Blow out the nipple oil passage and the spring guide.
2. Inspect the nipple and spring for free-motion, wear, and damage, and replace if necessary. Spring free-length should be $1^{15}/_{64}$ in.
3. Inspect the nipple threads and replace them if they are worn or damaged.
4. Replace the valve balls if they are ringed or are not perfectly smooth.
5. Inspect the ball valve seat for a clean and smooth condition. Slight pitting or striation marks can sometimes be removed by gently tapping with a suitable drift. Replace the pump body if such defects can not be corrected.

OIL PUMP CHECK VALVE ASSEMBLY

1. Assemble in the reverse order of disassembly.
2. All of the parts must be absolutely clean.

OIL PUMP INSPECTION

1. Clean all of the parts in a suitable solvent and blow them dry. Blow all passages free.
2. Replace all gaskets, the retaining ring, lockpin, and the oil seal. Homemade gaskets must be avoided since the proper thickness and proper passage holes are essential.
3. Replace all worn or damaged parts.
4. Inspect the pump body for wear or damage.

5. Inspect all of the gears for worn or damaged teeth and replace them as necessary.

6. Replace the breather valve key if it is worn or loose.

7. Inspect the breather valve and pump for wear and damage.

8. Check that the valve is a free fit.

OIL PUMP ASSEMBLY

1. Assemble in the reverse order of disassembly.

2. Lightly oil all of the moving parts.

3. Assemble the check valve as described in "Oil Pump Check Valve Assembly."

4. Place the breather valve screen in position and secure it with a daub of grease.

5. Assemble the breather valve in the oil pump cover and secure it with a lockpin.

6. Press a new scavenger-pump idler gear shaft into the pump body if the old one has been removed.

7. Assemble the pump gears to the pump body.

8. Secure the body gasket using a non-hardening sealer. The gasket must be carefully aligned to permit free oil passage.

9. Assemble the assembled breather valve and cover to the pump body.

10. Place a thin strip of acetate tape over the groove in the breather valve shaft. Install a new oil seal flush into the pump body counterbore with the seal's lip facing the body. Remove the tape.

11. Install the breather valve key and scavenger pump gears, and secure them with a retaining ring (or retainer, whichever is applicable).

12. Install a new body plate gasket using a non-hardening sealer. The gasket may be flattened if necessary by soaking it in water before sealing it.

13. Slide the oil pump and the body plate onto the crankcase studs, and evenly secure the studs.

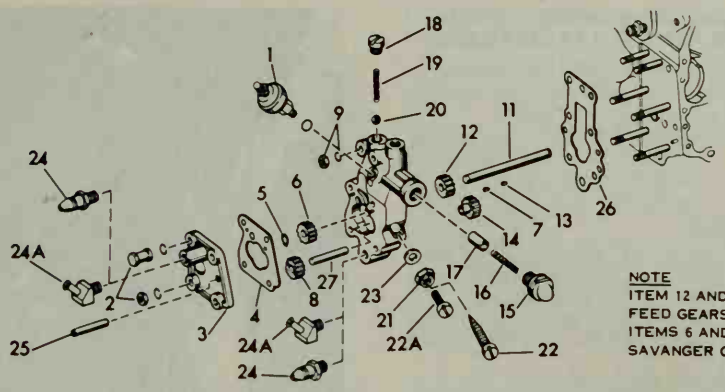
14. Check for free-motion of the gears. If the gears bind, the pump may be slightly out of alignment. Remedy this by loosening the stud nuts and gently tapping the pump with a soft mallet until the correct alignment is attained.

15. Time the breather valve as follows:

a. Remove the gearcase cover as described in "Gearcase Disassembly";

b. Rotate the engine until the flywheel timing mark is aligned in the crankcase view port;

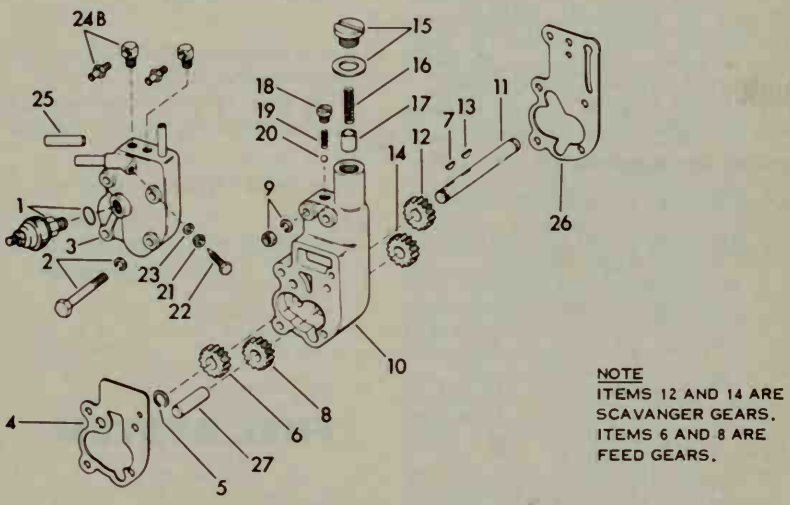
c. Position the breather gear so the valve hole aligns with the pump body hole;



d. Shift the breather gear two teeth to the right;

e. Place the breather screen and pump gasket in position;

f. Install the pump carefully on the mounting studs and the breather gear will then assume the correct timing position;



g. Check to be sure that the breather valve hole and the pump body hole are aligned. The flywheel timing mark must still be correctly aligned;

h. Assemble and secure the gearcase cover and pump.

OIL PUMP DISASSEMBLY (WITH ENGINE IN FRAME)

1. Disconnect the oil switch, feed, and scavenger lines from the pump body.

2. Remove the cover stud nuts or bolts and their washers.

3. Slip the oil pump cover and the cover gasket from the gearcase studs.

4. Remove the driveshaft snap-ring with snap-ring pliers, and then remove the drive gear, gear key, and idler gear.

5. Remove the stud nuts which mount the oil pump body and then remove the body.

6. Remove the oil pump gear driveshaft.

7. Remove the scavenger (1968 and later) or the feed (1967 and earlier) drive-gear, gear key, and the scavenger idler gear and key.

8. Remove the by-pass valve plug, spring, and spring sleeve.

9. Remove the check valve cover screw, spring, and ball valve.

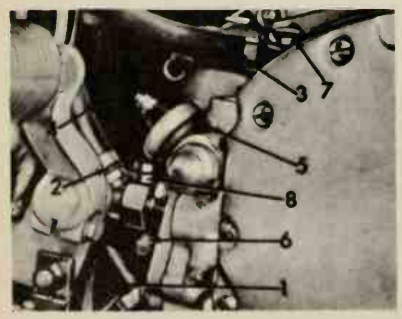
10. Loosen the chain oiler adjusting screw locknut (if applicable) and gently seat the adjusting screw while counting the number of turns necessary to seat it. Remove the adjusting screw and washer. The screw must be replaced in the same position during assembly.

11. Remove the chain oiler screw on 1965–67 models.

12. Remove the oil pump nipples.

13. Do not mix any gears or keys.

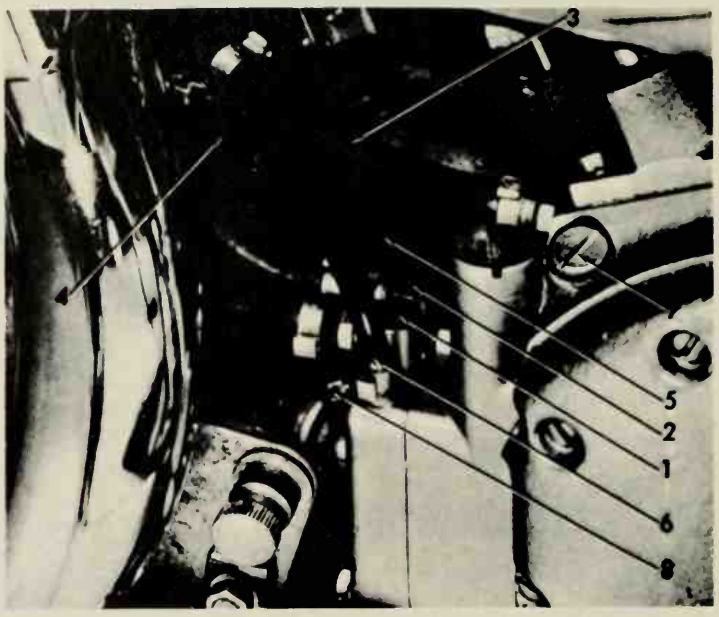
OIL PUMP DISASSEMBLY (WITH ENGINE REMOVED FROM FRAME)



1. Remove the engine from the frame.
2. Remove the gearcase cover securing screws, cover, and cover gasket.
3. Remove the left-hand threaded pinion gear nut from the pinion shaft using the Gear Shaft Nut Socket Wrench (H-D Part No. 94555-55); vise grips may be substituted.
4. Remove the pinion gear with Pinion Gear Puller (H-D Part No. 96830-51) or a suitable, standard gear puller.
5. Remove the pinion gear key, spring, spacing collar, and the oil pump pinion shaft gear.
6. Remove the pump drive-gear shaft spring-ring, drive gear, and shaft key.
7. Remove the pump body nuts and bolts, then slip the assembled pump and pump gear driveshaft from the gearcase.
8. Disassemble the pump as described in the previous section.

OIL PUMP INSPECTION

1. Clean all of the metal parts in a suitable solvent and blow them dry.
2. Blow all of the passages clear.
3. Inspect the valves and seats for pitting and wear, and replace the pump if its seats are damaged.
4. Inspect the keys and key seats for damage or excessive clearances—especially the pump gear shaft key if oil does not return to the tank, or the driveshaft key if oil is not being circulated.
5. Inspect all gears for wear or damage, and replace them if necessary.



OIL PUMP ASSEMBLY

1. Assemble in the reverse of disassembly.
2. All the gears and keys must be replaced in their proper locations.
3. Replace gaskets and lockrings. Only factory approved gaskets should be used.
4. Secure the bolts and nuts evenly to no more than 4–5 ft lbs torque or damage to the gasket and pump will result.
5. If leaks persist, replace the gaskets again. A small amount of non-hardening sealer may be used if great care is taken not to clog any passages.
6. Replace the oil hose clamps and squeeze them tight. Worm-type automotive hose clamps may be used and will require no special tools.
7. See Step 15 under Sportster "Oil Pump Assembly," for breather information.

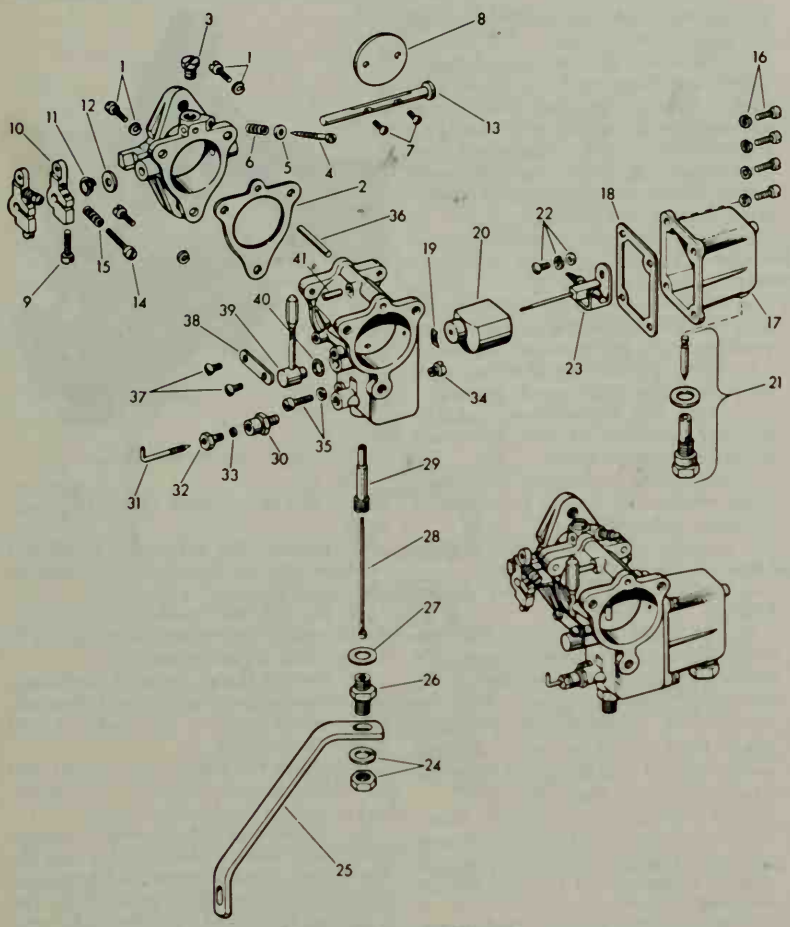
CARBURETOR

Linkert Model DC



The Model DC is a plain, tube-type carburetor with venturi, discharge nozzle, adjustable high- and low-speed needles, and a fixed jet. The only moving parts are the throttle shaft, disc, and float assemblies.

REMOVAL

1. Remove the air cleaner cover, element, and back plate.
2. Disconnect the fuel line at the carburetor.
3. Remove the carburetor bracket (if applicable).
4. Remove the two carburetor securing bolts and pull the carburetor out and off.

DISASSEMBLY

1. Remove the three throttle body screws, lockwashers, body gasket, idle hole body plug, low-speed needle valve, washer, and the needle valve spring from the throttle body.
2. Free the throttle disc from the shaft by removing the throttle shaft screws and lockwashers.
3. Remove the stop screw and spring from the throttle lever, then remove the throttle lever clamping screw from the lever. Remove the spring, washer, and shaft from the throttle body.
4. Remove the carburetor bowl, by tapping it gently, after having removed the four bowl attaching screws.
5. Carefully separate the bowl gasket from the bowl.
6. Free the float by removing the float rod and unscrewing the flat speed nut.
7. Lift the float valve and seat assembly free.
8. Remove the float lever and bracket assembly by removing the float lever screw, lockwasher, and float washer.
9. Remove the support bracket (if applicable), lockwasher, and nut.
10. Removing the bowl nut and gasket reveals the idle tube which should remain in the body. Do not attempt to remove it from the bowl nut, but, if it remains in the body after the bowl nut is removed, it must be removed by tugging gently at the plug end.
11. Remove the nozzle using a screwdriver with a clean, flat head to ensure that no damage is done to the jet orifice.

12. Free the high-speed needle valve, packing nut, and packing by removing the high-speed needle valve extension housing.

13. Remove the jet which is located directly across from the high-speed needle valve hole.

14. Free the idle passage tube by removing the drain plug and gasket.

15. Remove the vent housing, gasket, and idle bleed tube by removing the clamp and securing screws.

INSPECTION

1. Clean all of the parts, other than the gaskets and float, in a carbon and gum-dissolving solution such as Gunk Hydro-Seal® (which is recommended by the factory). Rinse thoroughly and blow them dry.

2. Clear all of the carburetor barrel passages with compressed air. Do not scrape the carbon deposits with any steel instrument.

3. Replace the throttle shaft if there is more than 0.002 in. play noticeable at the bearing.

4. Clean out the idle port holes in the throttle body with a drill bit if necessary, taking care not to increase the hole size. The proper drill bit size for models DC-1, 1L, 1M, and 10 is 0.028 in. (H-D Size No. 70); the DC-2 uses a 0.0465 in. (H-D Size No. 56) drill.

5. Open the idle jet hole with a 0.043 in. drill bit (H-D Size No. 57) and the angular hole which it meets with a 0.0635 in. drill bit (H-D Size No. 52).

6. Clear the nozzle bleed holes with a 0.055 in. drill bit (H-D Size No. 54) and the main passage with a 0.073 in. drill bit (H-D Size No. 17).

7. Clean the high-speed bit needle seat holes with a 0.052 in. drill bit (H-D Size No. 55) for models DC-1, 1L, 1M, 10, 6, 7, and 12. For model DC-2, use a 0.028 in. drill bit (H-D Size No. 70).

8. Check to see that the two vents in the carburetor body are open.

9. Be sure not to enlarge any passages and examine all of the connecting surfaces for possible leaks. Replace any leaky part or any part on which wear has caused excessive clearances.

ASSEMBLY

1. Assemble the vent housing assembly, gasket, idle bleed tube, clamp, and screw in the carburetor body.

2. Slip the tubes into their holes and tap the housing into place.

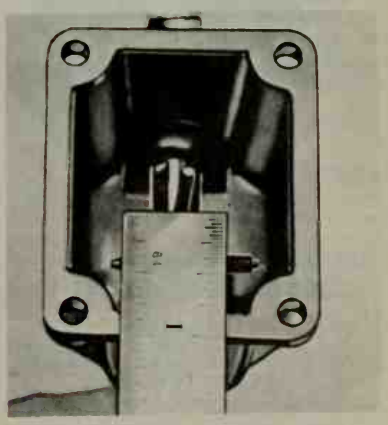
3. Secure the clamp just tight enough so that the outer ends will touch the body bosses.

4. Assemble the drain plug, gasket, and high-speed jet on the carburetor body.

5. Back out the needle valve before installing this assembly in the main body so that the point will not enter the valve hole when the two units are secured together.

6. Position the needle valve so it doesn't jam into the seat hole and cause damage.

7. Assemble the nozzle.



8. Locate the idle tube in the body hole and press it in until about 1/32 in. extends out from the nozzle hole.

9. Install the bowl nut and gasket; this should hold the idle tube in place.

10. Assemble the float valve and seat assembly, and install the float lever bracket screw loosely so that an adjustment can be made if necessary.

11. Holding the float valve and seat halfway into the bowl, align the lever fingers with the groove in the valve and bring them together while turning the valve into its seat. This must be done with the bowl removed from the body.

12. Invert the bowl and measure the distance from the top of the float rod to the outer edge of the bowl flange which is directly opposite the fuel inlet fitting. at the point where the float valve seats

Checking float setting

lightly, the distance should be 1 in. ± 1/64 in.

13. Adjust the slotted float lever bracket until the proper measurement is obtained and then secure the bracket screw.

14. Place the float on the rod with the flat side up and secure it with a speed nut.

15. Mount the bowl to the carburetor main body, taking care not to crush the gasket.

16. Insert the throttle shaft so that the screw seats align with the screw holes on the throttle disc and then loosely mount the throttle disc, with the identification number facing out.

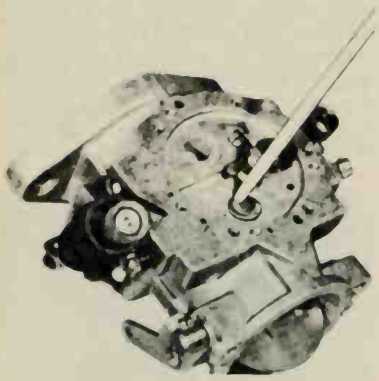
17. Rotate the disc and note whether it binds anywhere. When a position is obtained where movement is free, secure the disc and recheck its movement.

18. Install the throttle lever stop screw and spring.

19. Install the throttle lever, throttle shaft spring, and washer, and position them so that slight end-play exists when the lever is clamped tightly. Place the disc and lever in an open position and secure the throttle lever clamping screw.

20. Install the low-speed needle jet, washer, and spring, taking care not to bevel the seat with excessive pressure.

21. Secure the idle hole body plug.



22. Insert the idle passage tube into the carburetor body with the beveled end out.

23. Assemble the throttle body on the main body, using a new body gasket to ensure proper thickness. Do not use a homemade gasket because the correct thickness is critical.

24. Mount the carburetor and adjust it.

Tillotson Model HD

The model HD is a diaphragm-type carburetor.

Removing the welch plug

PRELIMINARY INSPECTION

(Complete all tests before replacing any parts.)

1. Without removing the carburetor, inspect the accelerating pump as follows:

a. Remove the air cleaner.

b. Prime the carburetor by gently manipulating the diaphragm with a toothpick which can be inserted through the small hole in the bottom of the plastic pump cover.

c. Twist the throttle several times, slowly and then rapidly, with the petcock in the open position. Observe the action of the pump and note whether a constant jet of fuel is delivered with each stroke. Replace the diaphragm valves and/or pump plunger if the desired result is not obtained.

2. Clean the high, intermediate, and low-speed passages in the following manner:

a. Remove the high-speed screw plug from the rear of the carburetor and gently seat the intermediate needle.

b. Apply a maximum of 90 lbs of air pressure to the high-speed channel.

c. Open the intermediate and idle needles by three or four turns and apply air pressure again.

d. Adjust the carburetor and determine whether or not the performance has been enhanced.

3. Test the inlet needle and seat for air leaks in the following manner:

a. Secure all plastic cover screws firmly.

b. Use Bulb Tester (H-D Part No. 94750-68) to pressure-check the needle and seat. With a tester installed in the carburetor inlet fitting and with the vent fitting plugged with a finger, apply 1–1½ lbs of pressure. A moist needle should hold about 3–5 lbs and is a better indicator than a dry one.

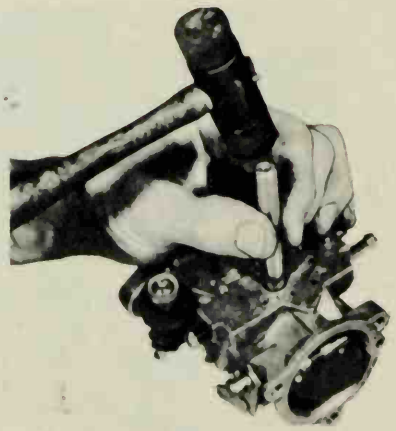
c. If a tester is not available, examine the needle tip. If excess pressure has been applied, the tip will appear slightly flattened and the seat will be beveled.

4. Remove the carburetor and inspect the intermediate adjustment needle and spring for binding which will prevent it from realizing its true seat.

a. Shorten each end of the spring with a grinder and test it for proper seating by applying blue dye to the end of the needle taper. Screw the taper lightly down into its seat and check to see if the blue has been disturbed.

5. Test the main nozzle ball check valve for leakage in the following manner:

a. Seal one end of the main jet port in the venturi with your finger and insert an appropriate size rubber tube into the opposite end of the venturi. Apply alternate vacuum and pressure. Pressure should cause the ball to seat and vacuum pressure should release the ball from the nozzle assembly.



b. Replace the main nozzle check valve assembly if any leakage is present.

c. Remove the welch plug by punching it off center with an appropriate punch. Drift it into the venturi gently, using a soft mallet and an appropriate drift.

d. Replace the new check valve using a drift. Drift (H-D Tool No. 96962-68) is available for these operations.

6. Examine the idle needle and seat for damage.

7. Examine the choke relief disc (upper half of the choke shutter) for damage.

Removing the main nozzle

8. Remove the diaphragm cover and examine the accelerator pump leather and spring for wear or damage.

9. On late 1968 models, examine the accelerator-pump outlet check-valve ball for freedom of movement.

10. Inspect the gasket and diaphragm for damage and replace them if their surfaces are not uniform. The gasket should adhere to the body.

11. Check the diaphragm washer and the diaphragm for excessive movement, and replace if drag is not present.

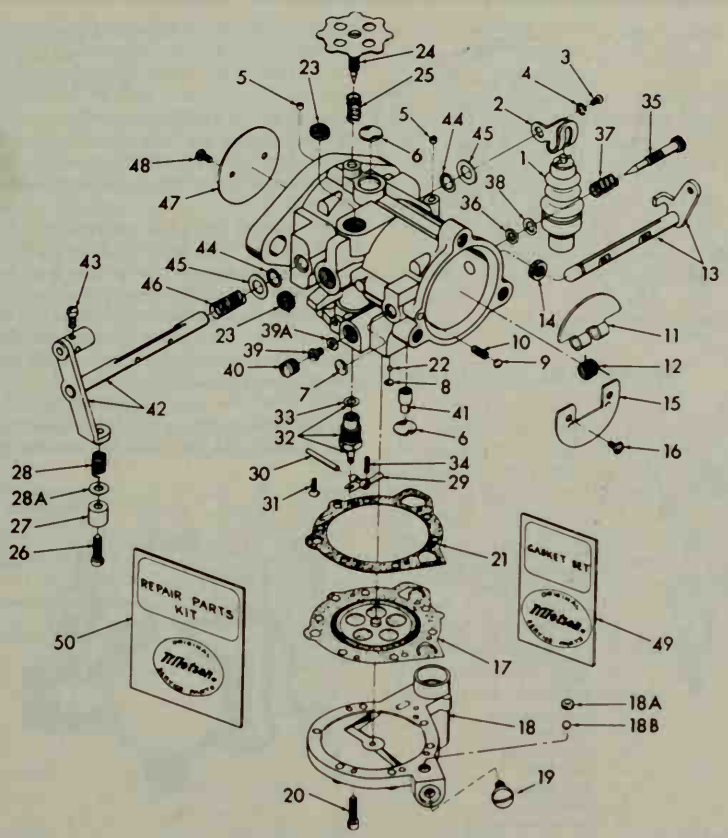
12. Check the inlet needle linkage with a bulb tester as described in step 3b. The valve on the tester should be closed and pressure should be asserted on the inlet port. Open and close the bulb valve about ten times while applying pressure to be sure that it isn't sticking closed.

13. The inlet lever should lie flush with the floor of the carburetor and it must be replaced if it doesn't. If it is not equipped with a shackled needle, substitute with kit No. 27588-66 and torque the seat to 45 in. lbs.

14. Check the economizer ball for proper operation in the following manner:

a. Using a rubber tube of the appropriate size, seal off the economizer welch plug hole and apply mouth pressure both in and out. If the ball does not release each time it is tested, replace it.

b. Inspect the welch plugs by attempting to move them in the body. Since they are a press-fit, they should not move. Replace any leaky or loose plug; never reuse a welch that has already been removed.



c. If the leak is due to a damaged seat, replace the plug and apply a small amount of seal-all or epoxy around the edges of the seat.

DISASSEMBLY

1. Remove the idle and intermediate fuel adjusters.

2. Remove the throttle butterfly mounting screws and the throttle butterfly. Note the position of the butterfly as an aid in reassembly.

slipped out of the body when the retaining screw is removed.

4. Remove the throttle shaft spring, washers, dust seals, accelerating pump assembly, diaphragm cover plug screw, metering diaphragm, and metering diaphragm gasket. Note that the gasket is mounted next to the body.

5. Remove the inlet control lever screw, inlet control lever pin, inlet control lever, and lever control tension spring.

6. Remove the inlet needle, seat, and needle gasket, taking note of proper positioning for replacement.

7. Remove the main jet plug screw, jet, and gasket.

8. Remove the main jet welch plug by drilling a shallow hole off-center with a ⅛ in. drill and then prying it free with a small punch. If you go too deep, the jet will probably be damaged.

9. Remove the remaining three welch plugs in the same manner and the economizer ball will then come free.

10. Remove the choke butterfly securing screws and the lower half of the choke butterfly.

11. Remove the choke shaft and then the upper half of the butterfly, the spring, choke friction ball, and the friction ball spring will all come free.

12. Slide the choke shaft dust seal off the shaft.

INSPECTION

1. Remove all plastic parts and gaskets then clean all of the metal parts in a solvent. Hydroseal solvent is recommended.

2. Blow all passages clear with compressed air. Never use wire to poke the passages free as this causes burrs or increases the port diameters.

3. Inspect all parts for wear and replace any parts which were either found defective in tests or appeared to be excessively worn.

4. If the inlet control lever does not rotate freely on its pin or if the forked end does not firmly engage the needle, it must be replaced.

5. Replace the inlet control lever tension spring if it appears to be stretched or damaged.

6. If the inlet needle point is worn or damaged or if the contact end does not provide a snug fit, they must be replaced.

ASSEMBLY

1. Examine all parts for small particles of dirt which can clog the small passages and blow them clean.

2. Assemble in reverse order of disassembly.

3. Seat the welch plugs with the recommended tool, or with a flat end drift of a diameter slightly smaller than that of the welch. A flat (rather than concave) surface is a good indication of a well-seated plug.

4. Mount the metering spring on the stud on the lever and seat it in the indentation on the body casting.

5. Torque the inlet seat assembly to 40–45 in. lbs and torque the accelerating pump channel plug to 23–28 in lbs.

Bendix Model 16P12

The model 16P12 carburetor is equipped with a dual venturi, an accelerating pump a fixed main jet, an idle stop screw, a low-speed idle screw, and a ring float.

DISASSEMBLY

1. Remove the air cleaner cover, element, and the back plate.

2. Close the petcock and disconnect the fuel line.

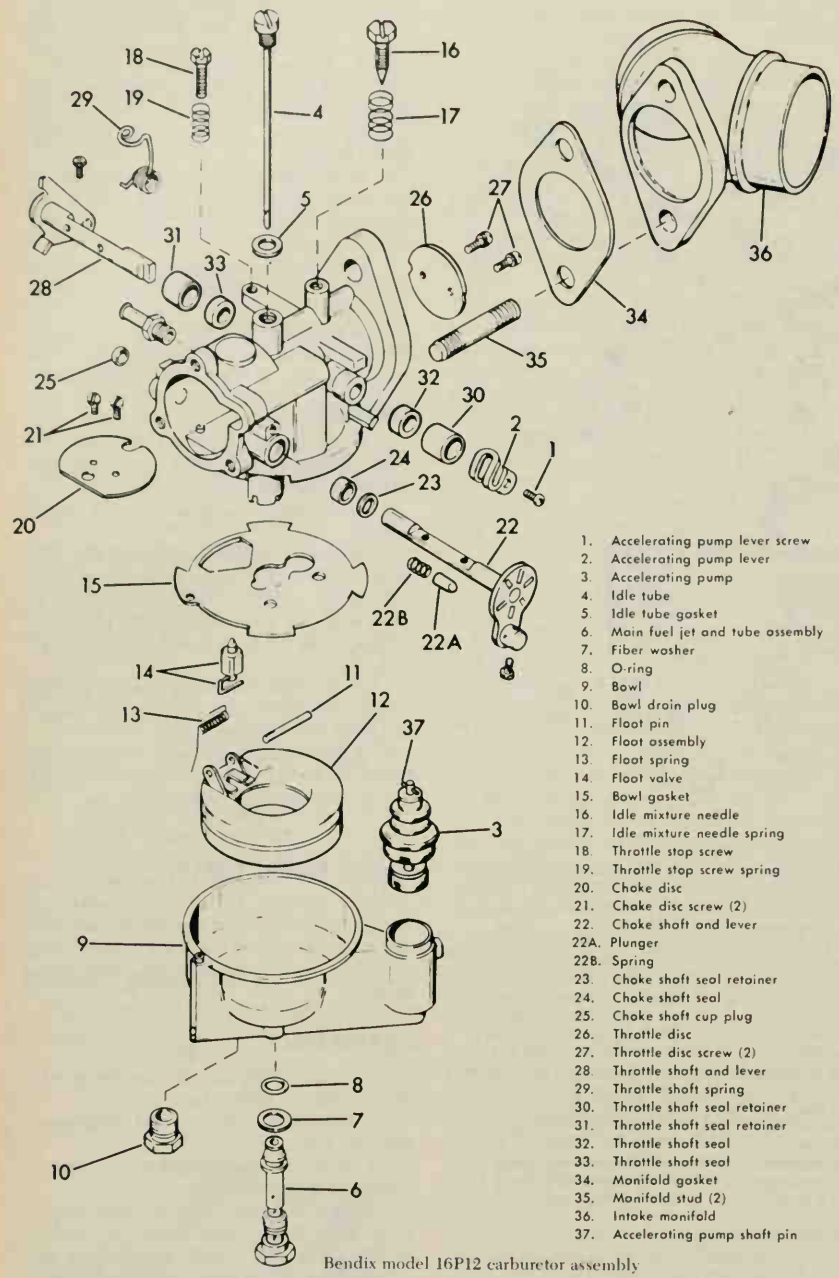
3. Disconnect the choke and throttle cables at the carburetor.

4. Remove the accelerating pump lever screw, lever and pump assembly, and remove the piston by rotating the pump lever 90 degrees while compressing the piston shaft spring.

5. Remove the idle tube, tube gasket, main jet and tube assembly, fiber washer, rubber O-ring, float bowl, and bowl drain plug.

6. Press the float pin through the float ears.

7. Lift the float, float spring, and float valve free from the bowl.



8. Remove the bowl gasket.

9. Remove the idle needle, spring throttle stop screw, and spring.

10. Remove the choke disc securing screws and disc.

11. Slide the choke shaft and lever assembly free from the housing and remove the plunger, spring, seal retainer, and seal.

12. Remove the choke shaft cup plug only if replacement is necessary.

Bendix model 16P12 carburetor assembly

13. Remove the throttle disc securing screws, disc, shaft and lever assembly, and shaft spring.

14. Do not remove either throttle shaft seal retainer unless replacement is necessary.

INSPECTION

1. Clean all metal parts in a carbon and gum-dissolving solution such as Gunk Hydro-Seal® (which is recommended by the factory), rinse thoroughly, and blow them dry.

2. Blow all passages, channels, and jets clear from both directions. Do not try to clear the jets with wire or a drill.

3. Inspect all of the parts for damage, wear, or a pitted condition and replace as necessary.

4. Use all of the parts in the repair kit if such a kit is used.

ASSEMBLY

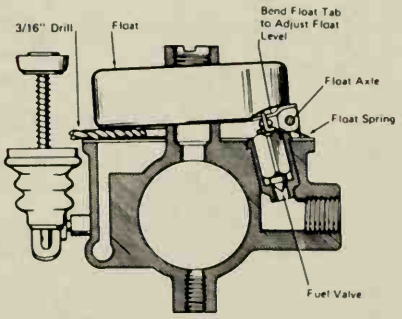
1. Assemble in reverse order of disassembly.

2. With the throttle return spring in place on the shaft, slip the shaft into the seal retainer and seal.

3. Install the shaft from the nipple side of the carburetor and secure the seal and retainer on the shaft hole boss on the opposite side of the carburetor bore.

4. Install the throttle disc on the flat side of the shaft with disc screws. Operate the shaft rapidly several times to center the disc and then secure the screws.

5. Install the choke shaft seal and retainer in the shaft hole and position the starter retainer by using a small punch.



6. Install the shaft through the housing on the opposite side of the throttle lever. Center and secure it in the same manner as was used for the throttle disc.

7. Install a new cup plug in the choke shaft hole if the original plug has been removed.

8. Install the bowl gasket.

9. Install the float valve in the bowl, hold the spring between the float ears, and then install the float pin. The valve clip must be attached to the float tab with a minimum clearance of 0.010 in. Bend the clip if it is necessary in order to attain the proper clearance.

10. With the bowl inverted, slip a 3/16 in. drill bit between the bowl gasket and the float. Bend the tab with needle-nose

pliers until the bit is in contact with both the gasket and the float.

11. Install the throttle stop screw and spring, and turn it in slightly. The no. 2 idle discharge hole must not be uncovered by the throttle disc.

12. Assemble the spring on the idle mixture needle and gently screw it in until it seats, then back it out 1½ turns (72–73) or 2¼ turns (74 and later).

13. Gently place the accelerating pump cup into the pump well and seat the pump boot around the top of the pump boss.

14. Assemble the fiber washer and rubber O-ring on the main jet. The O-ring must seat in the groove near the end of the tube.

15. Check to make sure that the accelerating jet fits properly in the throttle body.

16. With the carburetor inverted and the long end of the spring against the float, install the float bowl. The long end of the spring should seat against the side of the bowl.

17. Loosely install the main jet and secure the drain plug in the bottom of the bowl.

18. Install the idle tube gasket and the tube end in the discharge tube. Secure the idle tube and the main jet.

19. Assemble the accelerating pump lever to the pump and throttle shaft.

Keihin Carburetor

REMOVAL

1. Remove the air cleaner. Disconnect the throttle and choke cables from the carburetor.

2. Remove the mounting nuts and take off the carburetor.

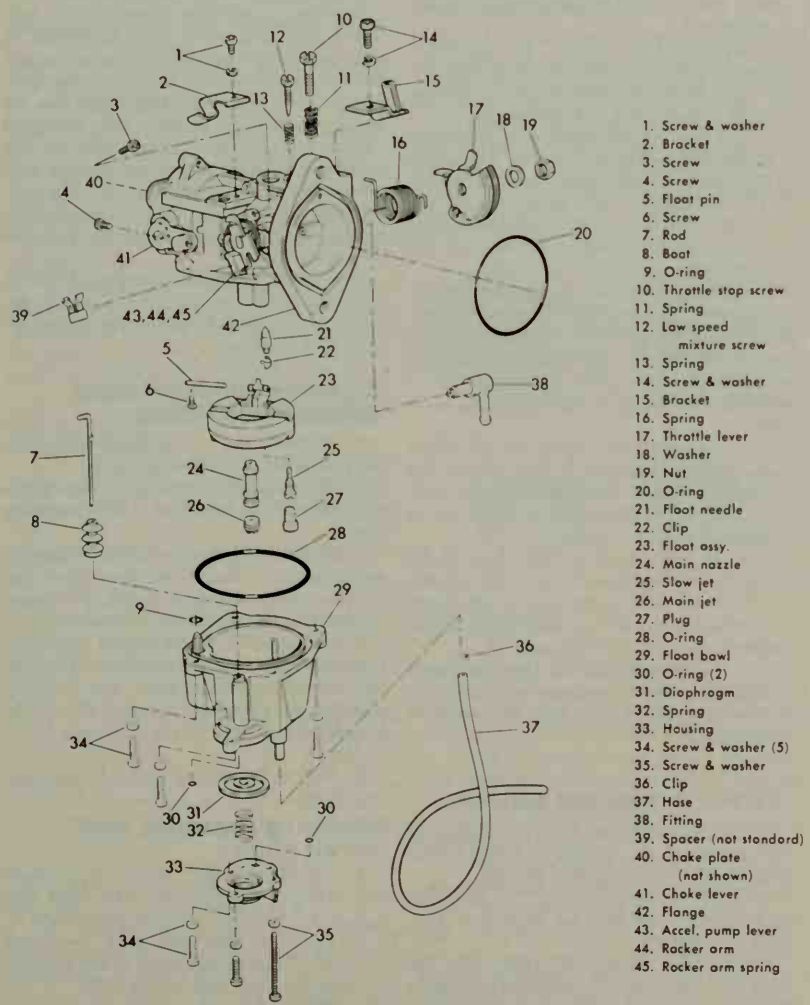
DISASSEMBLY

1. To disassemble the accelerator pump, remove the pump housing (3 screws), remove the spring, diaphragm, and o-rings. Note the spring when removing the housing.
2. Remove the float bowl screws. Take off the float bowl. Remove the float pin securing screw; remove the pin,and take out the float. Remove the float needle.
3. Remove the pump rod and boot from the float bowl.
4. Remove the plug over the slow jet. Unscrew the slow and main jets. Take out the main nozzle.
5. Remove the mounting flange o-ring.
6. Remove the throttle lever and spring.
7. Unscrew and remove the throttle stop and low speed mixture screws, which will have springs on them.
8. Remove the brackets, if necessary.
9. The throttle and choke valves are not removeable.

INSPECTION

1. Clean all metal parts in a safe solvent.
2. Check the accelerator pump diaphragm for condition. Replace it if cracked or punctured.
3. Blow the accelerator pump passage clear, which should be done from the side opposite the nozzle.
4. Blow all air and fuel passages clear with compressed air.

ASSEMBLY



1. Assembly is the reverse of disassembly. The use of new o-rings is recommended.
2. Adjust the float level as outlined below.

FLOAT LEVEL ADJUSTMENT

1. There are two adjustments.
2. Check float level with the valve closed. Turn the carburetor upside down and let the float hold the needle against its seat. Measure the distance from the float bowl mating surface to the top surface of the float. It should be 0.55–0.63 in. (14.0–16.0 mm). If adjustment is necessary, bend the lip of the metal tab which secures the float needle.
3. Turn the carburetor to the normal installation position. The float will hang down so that the float valve is full open. Measure the distance between the float bowl mating surface and the bottom of the float. It should be 1.10–1.18 in. (28.0–30.0 mm). If adjustment is necessary, bend the stopper of the metal tab on the float.

INSTALLATION

1. Be sure the mounting flange o-ring is firmly in place. Tighten mounting bolts evenly.
2. Attach cables and check operation. Secure fuel lines, and be sure the overflow tube points away from the engine.

Keihin carburetor

PETCOCK

1974 and Earlier

1. The diaphragm-type petcock, or fuel valve, has two handles. The petcock will pass fuel when the handles are in the vertical position. Turned horizontally, the fuel will be shut off.
2. Shims of a thickness of 0.006 in. (Part No. 616OP) are available in the event that handle movement is too loose.

1975 and Later

1. This petcock has a single handle. "Off," "On," and "Reserve" positions are marked.
2. Disconnect the fuel line and check fuel flow in each position. If operation is faulty, replace the petcock.

ELECTRICAL SYSTEM

CHARGING SYSTEM

Generator-Equipped Models

On DC generator-equipped models, the standard generator used is a two-pole, two-brush unit of conventional construction. Two types of regulator have been used throughout the years, the two-relay type voltage regulator and the three-relay type voltage/current regulator.

TROUBLESHOOTING THE GENERATING SYSTEM

The following is the most direct approach to take in locating the source of generating system difficulties:

1. The following items are indicators of a faulty generating system:
   a. Failure of the generator light to operate.
   b. Repeated or sudden battery discharging.
   c. Excessive battery water evaporation indicating an overcharged state.
2. In testing the generating system, do not commit the following mistakes which will result in damage to the system:

a. Do not reverse the generator polarity.

b. Do not short or ground any wires unless specifically instructed to do so.

c. Do not operate the engine while the generator output terminal is disconnected.

d. Always connect positive to positive and negative to negative when connecting a charger or booster to the battery.

3. Check for a faulty generator light in the following manner:

a. If the ignition switch is turned off and the light is on, disconnect the generator 1 and 2 leads at their terminals. If the light stays on, check for a short between these two leads. Replace the rectifier bridge if the light goes out. Failure to remedy this situation will result in a discharged battery.

b. If the generator light doesn't go on when the ignition switch is turned on, check for a short between leads 1 and 2. If the light still doesn't come on, reverse the two leads. If the light still hasn't come on, check for an open circuit in the following manner:

(A) Connect the two leads of a voltmeter to ground and the No. 2 generator terminal, and check for a reading. Go on to the next step if a reading is obtained. No reading indicates an open circuit between No. 2 terminal and the battery. Correct this, then see if the light goes on when the ignition is turned on.

(B) Either connect or disconnect both No. 1 and 2 generator leads, turn the ignition switch on, and momentarily ground No. 1 terminal lead only. If the light does not come on, check for a burned out bulb, blown fuse, faulty bulb socket, or an open condition between No. 1 terminal and the ignition switch. Remove the ground from No. 1 terminal if the light comes on, and with No. 1 and 2 terminals connected, ground generator by inserting a screwdriver into the generator test hole.

(C) If the light still hasn't come on, check for open circuits between the wiring harness and the No. 1 terminal, generator brushes, slip rings, and field windings.

(D) If the light came on in the first step and there was a voltmeter reading, replace the regulator.

(E) Consult the next section if the light stays on when the motor is running.

4. Locate the reason for an undercharged battery in the following manner:

a. Make sure the reason the battery keeps going down is not because the accessories have been left on without the engine running.

b. Check the drive belt for proper tension.

c. Check the battery for shorting with a voltmeter or hydrometer indicated by one or more dead cells.

d. Inspect all wiring for loose or poor connections.

e. Connect the leads of a voltmeter from ground to the generator "BAT" terminal, then the No. 1 terminal, then the No. 2 terminal. No reading indicates an open condition between the battery and the voltmeter connection.

5. Check the generator in the following manner if the problem hasn't yet been discovered:

a. Disconnect the battery ground wire, connect an ammeter so the current will pass through it from the generator "BAT" terminal to the lead which was connected to the "BAT" terminal, and reconnect the battery ground wire.

b. Turn on all of the accessories and attach a carbon pile across the battery terminals. Operate the engine until maximum current output is obtained.

c. If generator is good, amperage output will be within 10 percent of output stamped on generator frame. Go back and recheck the previous steps.

d. Ground the generator by inserting a screwdriver through the generator test hole if amperage isn't within 10 percent of its normal rating.

e. Recheck with a carbon pile as described above. If the reading is still not within 10 percent, the regulator must be replaced.

f. Recheck with a carbon pile and overhaul the generator if the reading still isn't within 10 percent of its rated amperage.

6. Locate the reason for an overcharged battery in the following manner:

a. Check the state of battery charge with a voltmeter or hydrometer.

b. Connect the leads of a voltmeter to ground and generator No. 2 terminal to check for an open reading (zero). The voltage, in any case, should not exceed 16.0 volts at 0° F. Discrepancies in measurements taken in cold and hot conditions are to be expected.

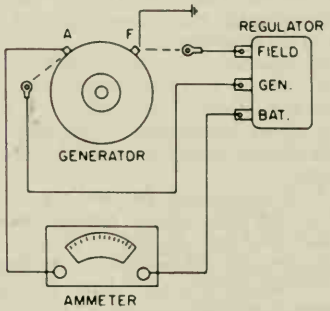
7. If the above test proves that the circuit is good and excessive water evaporation still indicates an overcharged battery, separate the generator end frames and check the field windings for a shorted condition in the following manner:

a. Connect the leads of an ohmmeter from the brush lead clip to the end frame and then reverse the connections. The ohmmeter must be set on its lowest range scale.

b. If both readings are zero, check for a grounded brush lead. This is probably caused by a missing or damaged insulating washer or insulating screw sleeve.

c. If, after replacing the insulating elements, both readings are still zero, the regulator is defective and must be replaced.

TESTING GENERATOR OUTPUT



1. Remove the wire from the generator "F" terminal and connect a jumper wire from the "F" terminal to ground.

2. Remove wire(s) from "A" terminal and connect the positive lead to a 0–30 amp ammeter.

3. Run the engine at 2,000 rpm (40 mph in Fourth gear) and briefly connect the negative lead of the ammeter to the positive battery terminal.

NOTE: *Avoid running the engine for long periods with the generator field grounded, and always disconnect the ammeter lead from the battery before stopping the engine so the battery doesn't discharge through the generator.*

CAUTION: *Disconnect the wires from the regulator before grounding the regulator "F" (XLH) or "BT" (XLCH) terminals to check output, or regulator will be damaged.*

Generator output test

4. If the ammeter reads 10 amps, the generator is good and the trouble is in the voltage regulator or wiring circuit.

5. When installing generators or batteries and whenever the generator or regulator wires have been disconnected, flash the field coils to make sure the generator has correct polarity. Do this by briefly touching a jumper wire between "BAT" and "GEN" terminals on the regulator before starting the engine and after connecting all of the wires. The momentary surge of current from the battery to the generator will correctly polarize the generator.

NOTE: *If generator output findings are negative, consult the following section before removing the generator for further testing.*

CLEANING AND INSPECTING GENERATOR BRUSHES

1. Remove the commutator end cover nuts, washers, and frame screws.

2. Pry or gently tap off the commutator end cover from the frame and armature shaft.

3. Remove the brush holder mounting plate from the frame and disconnect the brush wires and generator positive brush cable from the brush holder terminals.

4. Remove the brushes and clean the holders with a suitable solvent. Replace the brushes when they are broken, gummy, or worn to the point where the longest side of the brush measures ½ in. or less.

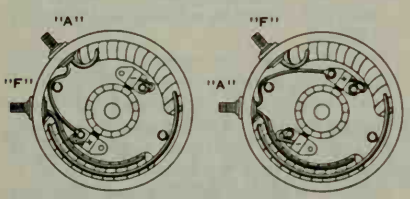
5. Seat new brushes with a brush seating stone.

GENERATOR REMOVAL AND INSTALLATION

1. Disconnect the "BAT" wires from the voltage regulator terminal and disconnect the wires from the generator.

2. Take out the two long generator mounting screws and remove the generator from the left-side of the bike.

3. Install the generator in the reverse order of removal.



GENERATOR DISASSEMBLY AND COMPONENT TESTING

Testing Field Coils

An ammeter will react to an overload by sending its needle beyond the range of the calibrated scale. A direct short causes the needle to swing violently to the end of its travel. In both cases, damage will result to the ammeter if contact is not instantly broken. In testing field coils, first make sure there is no short present by making brief contact before securing the test lead. Try to work on a non-conductive surface and never touch the test points together.

The test is made by linking together an ammeter and a battery in series, with the components to be tested connected to leads.

1. Remove or insulate the brushes from armature.

1965 MODEL 65-12V. 1966 MODEL 65A-12V.

Internal connections of brushes to field terminals

2. Touch one test lead to "F" terminal and ground the other to the generator frame. There should be no reading.

3. Touch one test lead to "A" terminal and ground the other. If there is a reading for either, there is a grounded terminal or else the field coil is grounded to the frame.

4. Check terminal-to-ground contact. No reading means that the terminals are properly insulated. If there was a reading in Steps 2 or 3, but there is not now, the trouble is probably a grounded field coil.

5. Remove the generator drive gear using a gear puller. (H-D puller is Part No. 95715-19A.)

6. Press the armature out of the ball bearings with an arbor press. This can be done by placing the generator frame between the copper jaws of a vice and tapping the gearshaft end with a soft mallet.

7. Disassemble the terminals and remove the field coil leads. Examine all of the terminal components for wear and damage, especially all of the insulators. Replace any that are worn. Assemble all components except the field coil leads.

8. Touch one test lead to the field coil lead and the other to the ground on the generator frame. Check the other coil lead. A reading means that the coil is grounded and that the two coils must be separated by cutting the wire which connects them.

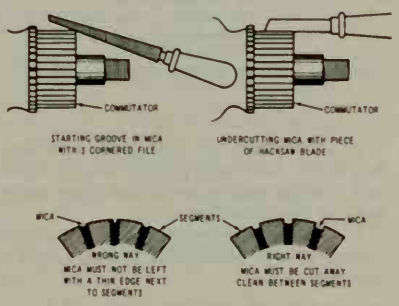
9. Test each field coil as above. A reading means that there is a grounded coil which must be replaced.

10. Test the field coils by touching the test leads to the coil lead terminals. The 6 volt double coils should produce a reading of 0.2 amps; 12 volt double coils should produce a reading of 2.3 amps (1965 models). No reading means an open coil. A higher reading means a shorted coil.

11. Strip back the insulation and scrape the wire clean where the two coil leads are joined. Attach one test lead at this point and the other at either coil lead. The 12 volt coils should produce 4.6 amp (1965 models) readings. Test the other coil lead. No reading means an open coil. A higher reading means a shorted coil. Replace any faulty parts.

12. Touch one test lead to the brush holder mounting plate and the other to the positive (insulated) brush holder. A reading indicates a shorted holder. Clean, check, and replace the plate if necessary.

13. Check the negative brush holder to see that it is securely mounted and well grounded.



14. If the problem has not been located, it is probably the armature.

Testing the Armature

Check for electrical continuity between the armature core and the commutator. If continuity exists, the armature is defective and should be replaced.

Repairing Commutator

The commutator can be turned down on a lathe or sanded with fine "00" sandpaper. Never use emery paper since particles will embed, causing arcing. The mica insulation must be 0.025 in. below the surface of the sections and can be reduced to this point with a hacksaw blade if care is taken to keep the slot bottoms square.

Disassembly

1. Remove the gasket, gear shaft nut, and washer.

2. Remove the drive gear with a gear puller (H-D Part No. 95715-19A) and slip the drive end oil deflector off the shaft.

3. Remove the brush cover strap and the end nuts and washers, then pull the screws out of the frame.

4. Loosen and remove the end cover with a soft mallet.

5. Remove the brush holder mounting plate and securing apparatus.

6. Press the armature out of the bearing with an arbor press, which can be found in any machine shop, or by clamping the generator in a copper-jawed vise and striking the shaft end with a soft mallet.

7. Remove the terminal screws, nuts, washers, insulator, and positive brush cable.

8. Remove the end plate by tapping gently and remove the bearing retainer with needlenose pliers.

9. Press the armature bearing out of drive end plate and remove the bearing retainer.

10. Press the armature oil seal out of the drive end plate from drive-gear side.

11. Remove the two pole screws with a large screwdriver and remove the pole shoes and field coils (only if replacement is necessary).

Inspection

1. Clean all parts except the armature, coils, and brushes in cleaning solvent, and wipe all other components with a cloth soaked in solvent.

2. Inspect all part for excessive wear, especially the insulators, armature windings, coil wrappings, and pole shoe surfaces.

3. Replace the oil seal if the armature looks oily.

4. Replace any part of the brush holder mounting assembly which is bent.

5. Check for excessive play of the armature shaft in the end cover bushing or roller bearing.

6. Bushings can be removed best with a bushing puller (H-D Part No. 97250-58) and an arbor. Be sure that the new bushing seats firmly in the bearing recess in the generator drive end plate.

7. To remove an arbor from the generator case, insert a screwdriver to assist in twisting it out.

8. Roller bearings are removed by pressing and new bearings should be pressed in until the bearing end is flush with the end cover.

9. Replace ball bearings if play is present. Always pack the bearings with a suitable grease.

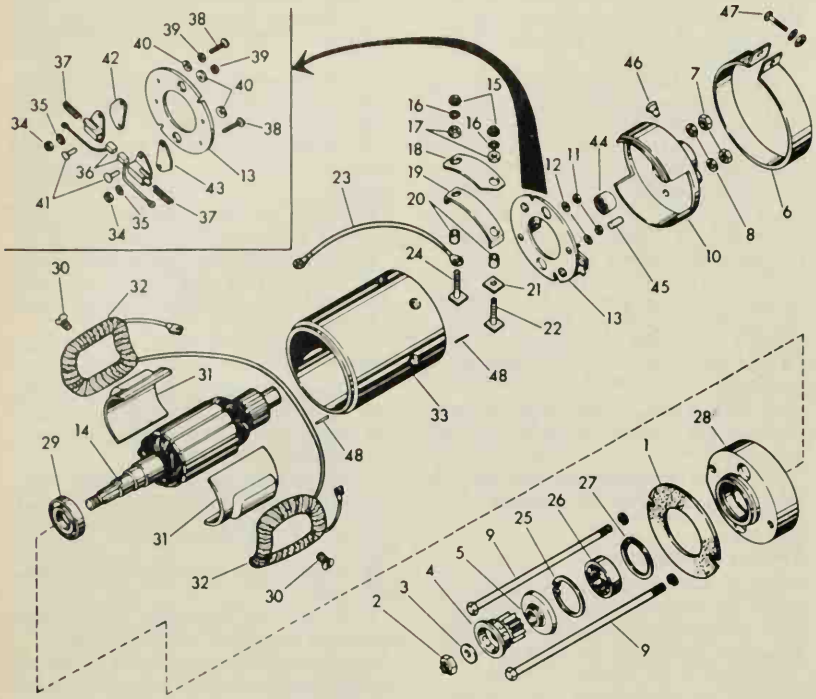
Assembly

1 Assemble all related parts to the brush holder mounting plate.

2. Place the pole shoes in the field coils and insert into the frame. Tighten the pole shoe screws with a large screwdriver and vise grips until the shoes align themselves in the frame.

3. Place the bearing retainer in the inner groove of the drive end plate and press the bearing in until it finds its seat on the retainer. Compress the bearing retainer with needlenose pliers and secure it in the outer groove.

4. Press the oil seal into the drive end plate.



5. Insert the armature drive end shaft and press it in until it is properly seated.

6. Assemble the "A" terminal coil lead, positive brush cable, terminal screw bushing, bolt clip and terminal insulator on the positive terminal screw.

7. Insert the assembled "A" terminal through the terminal frame hole from inside and secure it with the insulating washer, lockwasher, and terminal screw nut.

8. Assemble the "F" terminal and secure it from the inside out.

9. Slip the frame over the armature,

10. Draw the loose end of the positive brush cable out from the commutator end of the frame.

11. Push the brushes back in their holders to clear the commutator and install the assembled brush mounting plate over the commutator so that the pin lines up with the slot and the brush cable passes through the opposite slot.

12. Secure the positive brush cable and lead to the insulated terminal. Secure the negative brush to the grounded terminal.

13. Place the commutator end cover over the end of the shaft so that the frame pin and notch are aligned.

14. Install the internal lockwashers on the frame screws by feeding them through the generator drive end and secure them from the outside.

15. Check to see if the armature is stuck or if the core strikes the pole shoes, by rotating the shaft. The shaft should turn evenly when pressure is applied. If the core strikes the pole shoes, either the shoes or the generator ends are not properly situated.

16. Assemble the drive end oil deflector, drive gear, and washer on the shaft and tighten them until the gear seats against the oil deflector.

17. Install the brush cover strap and install a new mounting gasket, using a suitable sealer.

FAN COOLED GENERATOR

The fan-cooled generator is basically the same as the standard unit, but is physically larger—capable of generating higher current—and is equipped with a heat-dissipating fan.

Tests concerning this type of generator are the same except that its output is 20 or more amps and the field coils have four leads instead of two. Also, when testing the field coils, the ammeter should read for each coil.

Disassembly

1. Remove the fan housing and associated hardware.

2. Remove the armature shaft nut and washers. Use a gear puller (H-D Part No. 95635-46) to separate the fan from the shaft and remove the key (if applicable).

3. Remove the baffle screws, plate, fan spacer, housing spider, and end plate. Use a gear puller to remove the brush and bearing housing. The bearing should come off with the housing, but leave it there if it doesn't.

4. Remove the terminal screws and the brush and spring assemblies will come out of their holders.

5. If the field coils are to be tested, they are now accessible and no further disassembly is necessary.

6. Drive the clutch spring collar pin out of the collar (Duo-Glide).

7. Remove the clutch spring and drive gear from the armature shaft and use a gear puller to separate the clutch from the shaft. Slip the oil deflector from the shaft.

8. Remove the end frame with a bearing, gasket, oil retainer, and bearing shims (if applicable). This can be done best by loosening the frame screws about ¼ in. and tapping on them to unseat the frame end. Note the number and position of shims.

9. Remove the armature from the frame with an arbor press or soft mallet.

10. Remove the drive end ball bearing, spring ring, and felt grease retainer.

11. Remove the brush holders only if tests prove that the positive terminal is shorted, or if they are damaged. This can be done after the negative brush holder screws and terminal screw nuts are removed.

12. If the pole shoes or field coils are to be replaced, they can be removed by loosening the retaining screws and tapping their heads.

13. Remove the air intake shields.

Inspection

Refer to the preceding "Inspection" section for the standard generator. Procedures are the same.

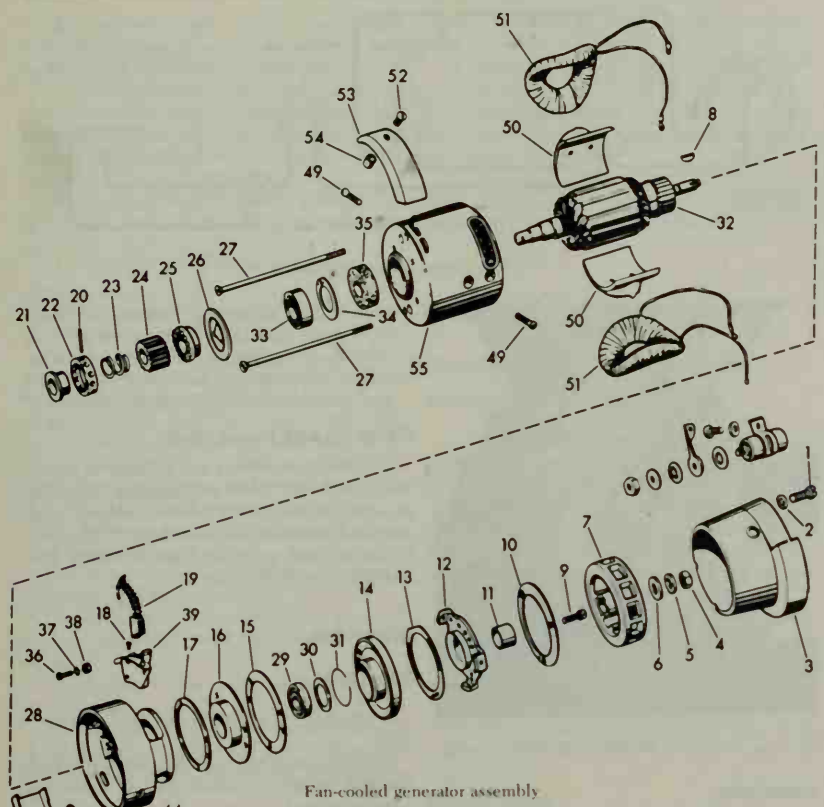
Assembly

Assemble the generator in reverse order of disassembly. Note the following points:

1. Install the field coils, armature, felt retainer, spring ring, and bearing. Use an arbor press to install the bearing.

2. Install the brush holders on the frame end and fit the frame end over the frame. The end may be drawn on by tightening the frame screws.

3. Route coil leads 1, 2, and 3 through the smaller frame opening, and lead 4 through the larger opening.



4. Run lead 1 behind and around the field coil terminal.

5. Twist leads 1 and 3 together and secure them to the field coil terminal with the terminal screw.

6. Install the positive brush. Twist leads 2 and 4 together and secure them to the positive brush terminal.

7. Assemble the negative brush only when lead 3 is positioned correctly behind the frame screw.

8. Assemble the commutator end of the generator in reverse order of disassembly making sure that the same number of shims are used.

Regulators

DELCO-REMY

Needed for testing are a voltmeter (20-volt range), and ammeter (30-amp range), and ¼ and 1½ ohm resistors and a 25W variable resistor.

1. Disconnect the wire to the "BAT" terminal of the regulator and connect the ammeter negative lead to the wire, and the positive lead to the regulator terminal.

2. Connect the voltmeter positive lead to the regulator "GEN" terminal and its negative lead to ground on the engine or frame.

3. Disconnect the regulator "F" terminal. Connect the wire to one side of the variable resistor. Connect the other resistor lead to ground. Set the field control knob to the open position.

4. Start and run the engine to 2,000 rpm and turn the resistor control knob until the ammeter reads 10a.

5. If this value is not obtainable, and the voltmeter reads less than 12v, the generator is at fault.

6. If the ammeter reading is obtained or if the voltmeter reading is more than 15v, the regulator is at fault.

7. While adjustment of the regulator is possible (referring to the appropriate Delco-Remy Service Bulletin), replacement is much easier.

BOSCH

Necessary equipment is as described for the Delco-Remy unit.

1. Disconnect the wire from the regulator "B+" terminal.

2. Connect one lead of a 1½ ohm resistor (at least 100W) to the terminal, and connect the other to the positive terminal of an ammeter. Connect the negative ammeter lead to ground.

3. Connect the positive lead of a voltmeter to the regulator "D+" terminal and the negative lead to ground.

4. Disconnect the wire from the regulator "DF" terminal and connect it to one side of the variable resistor. Connect the other resistor lead to ground. Turn the resistor control knob to the open position.

5. Start and run the engine at 2700 rpm. Turn the resistor control knob to the open position.

5. Start and run the engine at 2,700 rpm. Turn the resistor knob slowly towards the "Direct" position until the ammeter reads 10a, then turn it quickly back to open. If the 10a reading is obtained, the regulator is at fault. If the amperage reading is not obtainable and the voltmeter reads less than 12v, the generator is faulty.

6. The regulator is not repairable, and must be replaced in the event of faulty operation.

Alternator-Equipped Models

An alternator is used on 1970 and later Glide models. The alternator consists of twelve coils surrounding a permanently magnetized rotor fitted to the left end of the crankshaft.

1975 AND EARLIER

Observe the following precautions when working on alternator models:

a. Do not run the engine with the battery disconnected;

b. Do not disconnect or ground regulator or rectifier leads while the engine is running;

c. The battery MUST be disconnected if it is being charged on the motorcycle;

d. Reversing battery connections will destroy other electrical components immediately;

e. Do not connect a battery booster to start the engine with a low or dead battery.

Testing

Before testing, check that the battery is in good condition and fully charged. A low or defective battery will invalidate the test results.

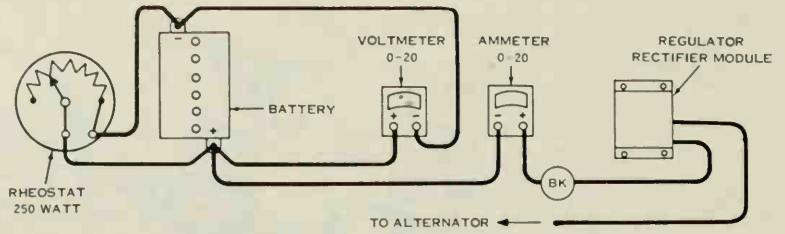
Be sure all electrical connections are clean and tight. The regulator module base must be well grounded to the crankcase: be sure the connection is clean and tight.

1. Connect an ammeter in series with the blue wire at the battery. Connect a 250W load rheostat (carbon pile) and voltmeter across the battery. With the rheostat off and the engine running at 3,600 rpm, the voltmeter should read 13.8–15.0 v, at room temperature (75° F). Note that voltage will vary with temperature: the higher the temperature, the higher the relative voltage reading may be.

2. With the engine running at 2,000 rpm, adjust the rheostat until the voltmeter reads 13.0 v. Ammeter reading should be at least 10.5 a. If it is not, proceded as follows:

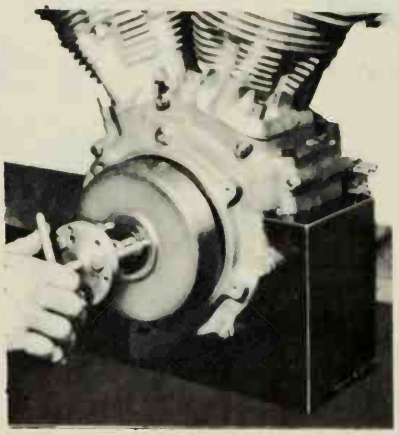
3. Disconnect the module plug from

the stator plug. With an ohmmeter or 12v continuity light, check connections at female connector. The results should be as follows:



PROBE CONNECTIONS	READING			
	+ Polarity		— Polarity	
	Light	Ohmmeter	Light	Ohmmeter
White to module base (GND)	Off	Infinity	On	3 to 15
White to module base (GND)	Off	Infinity	On	3 to 15
Blue to black	On	3 to 15	Off	Infinity
Red to module base (GND)	Off	Infinity	Off	Infinity

4. If results differ, replace the module. If correct results are obtained, check the stator at the male connector as follows:



Probe Connections	Reading	Replace Stator
White to white	0.3 to 1.0 ohms	0 indicates short circuit
White to blue	Both readings the same	
White to blue		
Blue to red	1.5 to 2.0 ohms	
Any pin to module base (GND)	Infinity	Any reading indicates short circuit

Removal and Disassembly

1. Remove the left footrest and chain housing cover. If a compensating sprocket is fitted, remove it.
2. Remove the chain adjuster mounting bolt and starter shaft thrust washer.
3. Remove the clutch adjusting screw locknut. Place a metal washer about 1¾ in. diameter with a ⅜ in. hole over the pushrod and fit the locknut.
4. Remove the spring tension adjusting nuts and pull off the clutch outer disc and spring collar assembly.
5. Remove the clutch sprocket and engine sprocket with chain.
6. Remove the three bolts securing the chain housing at the engine sprocket shaft. Loosen the transmission base mounting nuts. Remove the chain housing to transmission mounting bolts.
7. Remove the clutch hub (Tools 94645-41 and 95960-41A). Remove the shaft key. Remove the inner chain guard stud nuts. Disconnect the solenoid wire.
8. Remove the inner chain guard from the mainshaft (Tool 95960-41A). Disconnect the chain oiler hose at the pump. Disconnect remaining hoses at the rear of the chain housing.
9. Remove the sprocket spacer from the shaft. With tool 95960-52A, pull off the alternator rotor.
10. Remove the stator after removing the four screws and disconnecting wiring.

Alternator output test connections

Removing the alternator rotor

Installation

Installation is in the reverse order of removal. Note the following points:

1. Press the rotor onto the sprocket shaft using the Sprocket Shaft Bearing Tool (H-D Part No. 97225-55) until it bottoms firmly against the seal spacer.
2. Apply thread-locking compound to the transmission shaft bearing recess in the chain housing and to the shaft.
3. After the bearing housing is tapped into place, pack the race with grease.
4. Use aluminum paint on the chain housing and transmission surfaces where the two meet.
5. Replace the chain housing O-ring in the engine crankcase groove.
6. Replace the cover gasket.
7. Secure the transmission base mounting nuts only after the engine and transmission are secured to the chain housing.
8. Use a vacuum gauge (H-D Part No. 96950-68) to check the vacuum in the chain housing. With the vent tee hose closed off, the reading should be 20 in. Hg at 1,500 rpm. A lower reading is indicative of an air leak at the gasket, solenoid, starter shaft, or hoses.

1976 MODELS

1. Refer to the section "1975 and Earlier" for preliminary precautions which also apply to this system.

Testing

1. Refer to "1975 and Earlier" for test procedures. They are similar, except for the following points.

a. When checking voltage output (Step 1), the rheostat should be set for 3.5 a. Voltage should be 13.8–15.0v at room temperature.

b. When checking amperage (Step 2), output should be at least 14 a.

c. Coil resistance should be 0.2–0.4 ohms. Resistance between each pin and ground should be nearly infinite.

Removal and Installation

1. The procedures are similar to those described for "1975 and Earlier" models except that the stator plastic magnet ring must be installed on the stator before installation and must be flush or below the outside rim of the shell.

Magneto

REMOVAL

1. Remove the air cleaner and carburetor.
2. Disconnect the spark plug leads and the kill switch terminal wire at the magneto terminal.
3. Remove the tachometer drive assembly (if applicable) and loosen the control wire set screw.
4. Remove the mounting apparatus and lift the shaft and housing clear of the gearcase.

MAGNETO SPARK CHECK

1. Hold the end of the spark plug lead, with the plug cap removed, about ⅛ in. from the spark plug terminal. When the engine is running a blue spark should appear twice in every 360° rotation of the engine between the end of the lead and the plug terminal. If the spark is constant, the engine should not misfire. Do this on both plugs.
2. To test for spark with the engine off but the ignition on, hold the lead not more than ¼ in. from the plug terminal while kicking the engine over. Perform this on both plugs.
3. An easier test method is to remove the plug, reconnect the wire, and ground the plug tip against the cylinder head. Rotate the engine and watch for a blue spark at the plug tip.
4. If no spark is present, the kill button should be checked for a grounded condition before the magneto is removed for service.

DISASSEMBLY AND ASSEMBLY

1. Remove the end capscrews, end cap, and gasket.
2. Remove the spark plug leads. Remove the plug lead terminal by sliding up the lead protector and prying the terminal off with a screwdriver.
3. Remove the condenser mounting screw, washer, breaker arm terminal screw, condenser, and bracket.

4. Remove the point mounting screws, lockwashers, cam fiber and holder, and stationary contact point.

5. Remove the bearing support screws, safety gap (if applicable), and bearing support. Pry the rotor drive and grease retainer washer free, and remove the rotor cam end bearing.

6. Remove the rotor drive-gear pin by filing one end off and then punching it out.

7. Slip the rotor drive-gear from the shaft.

8. Remove the housing screws and slip the housing off the shaft.

9. Remove the O-ring and retainer washer, and drive out the bushing from within the housing (if applicable).

10. Remove the rotor drive and seal outer washer, rotor drive end seal, rotor drive, and grease retainer washer, then force the rotor drive-end snap-ring from the rotor shaft and remove the rotor.

11. Remove the rotor drive-end snap-ring and bearing.

12. Remove the coil bridge set screws, coil, and coil lead springs.

13. Remove the primary ground switch terminal and terminal switch wire.

14. Remove the vent cover screws, cover washers, cover, and screens.

15. Assemble in the reverse order of disassembly, taking care not to severely jar the rotor since this could cause damage.

GROUND SWITCH LOCK

Disassembly

1. Remove the end cap.

2. Remove the retainer clip between the insulating block and housing. This is best done by depressing the retainer clip with a knife, using the key in the switch as a lever, and pulling the key out to exert pressure while turning slightly to pull the lock out of the housing.

3. Remove the ground lock spring and lock ball from the ground-switch insulating block screw hole.

Assembly

1. With the retainer clip on top of the inside switch housing, insert the ground switch lock into the housing.

2. Depress the body retainer clip and push the ground lock switch into the housing, with a knife, so the clip engages the housing.

3. Loosen the condenser screw so the ground switch insulating block screw can be removed.

4. Replace the block screw and switch wire.

5. Replace the lock ball and lock spring.

6. Replace the switch insulating block wire and screw, and tighten the condenser screw.

7. Assemble the magneto in the reverse order of disassembly.

Installation

1. Set the oil seal ring and gasket (if applicable) in place on the gearcase.

2. Mount the magneto adaptor plate.

3. Install the magneto adaptor bolts from inside and tighten the assembly screws.

4. Manual retard magnetos must have the adaptor plates installed together.

5. Insert the rotor shaft into the gearcase and secure the magneto on the adaptor plate.

6. Manual retard magnetos must have the control arm installed before the mounting bolts can be replaced.

CONTACT BREAKERS

Contact Breaker Assembly Removal

1. Before attempting to remove the contact breaker assembly on early models, thoroughly clean the crankcase area around the unit as well as the contact breaker itself. To make sure that no dirt falls into the crankcase, have a clean oil soaked cloth handy to hold around the crankcase as the shaft is withdrawn.

2. On manual advance units, remove the contact breaker cover and cover retainer, then disconnect the spark control wire from the contact breaker cover.

3. On automatic advance units, remove the screw and lockwasher from the contact breaker cover and then remove the cover.

SPORTSTER

1. On 1965 models, remove the nuts and washer which secure the contact breaker base to the stem and remove the base.

2. Remove the two screws and the washer which secure the shaft and housing to the gearcase cover, and lift the shaft and housing free from the gearcase cover.

3. On 1966 automatic-advance types, remove the stem clamp bolts and clamp to free the entire unit clear from the crankcase.

GLIDE MODELS

1. On 1965 automatic-advance types, remove the nuts and washers, then slip the base from the housing. Now the entire unit is free to be lifted from the gearcase housing.

2. On 1966 automatic-advance types, upon removal of the stem clamp nut and clamp, the entire unit is free to be lifted clear of the gearcase cover.

CASE-MOUNTED CONTACT BREAKER

Glide models (1970 and later) and Sportster (1971 and later) have case-mounted breakers.

1. Remove the contact breaker cover and gasket by removing the cover screws.

2. Remove the wire terminal and wire from the breaker points.

3. Remove the contact breaker cam bolt, breaker plate bolts, lockwashers, and washers or screw retainer (whichever is applicable).

4. Remove the breaker assembly and free the contact assembly from the breaker plate by removing the breaker contact screw. Free the condenser lead and flat spring from the breaker contact terminal post. Remove the condenser screw, lockwasher, and condenser.

5. Remove the breaker cam and advance assembly.

6. Free the flyweight spring hooks from the pivot pin grooves and slip the fly-weights from the pivot pins. Springs need not be removed unless replacement is necessary. Flyweight roll pins are a press fit and need not be removed unless replacement is necessary

Installing Contact Breaker

1965 ELECTRA-GLIDE AUTOMATIC ADVANCE

1. Remove the spark plugs, put the machine in high gear on its center stand, remove the screw plug from the timing inspection hole, and telescope the front push rod.

2. Rotate the engine until the "F" mark on the flywheel is in position.

3. Lubricate the cam end of the shaft and stem assembly, and install the breaker cam on the shaft so that the notches in the cam engage with the flyweights.

4. Place the breaker base on the stem and shaft assembly and temporarily secure it.

5. The stem and base can only mount correctly in one way due to the stud positions. Check by aligning the base timing marks.

6. Install a new breaker rubber seal.

7. Turn the shaft counterclockwise 60 degrees from the position at which the cam mark and fiber align.

8. Temporarily insert the stem into the gearcase with the timing base marks away from the engine.

9. Align the flywheel timing mark in the fully retarded position.

10. Adjust the gear engagement, one tooth at a time, until the fiber and the cam mark align and secure the assembly to the gearcase.

11. Adjust the ignition timing.

1966 AND LATER ELECTRA-GLIDE AND SPORTSTER AUTOMATIC ADVANCE

1. Remove the spark plugs, put the machine in high gear on its center stand, remove the screw plug from the timing inspection hole, and telescope the front push rod.

2. Rotate the engine until the "Advance timing mark" on the flywheel is in position.

3. Install a new rubber seal.

4. Before installing, turn the shaft to approximately align the cam mark with the fiber follower.

5. Insert the breaker into the gearcase with the cable toward the rear of the engine. This will position the points to the outside of the engine to facilitate adjustment.

6. Align the flywheel timing mark in the center of the inspection hole and observe the position of the cam mark and fiber.

7. Lift the assembly and turn the shaft gear, one tooth at a time, until the

8. Adjust the ignition timing.

1970 AND LATER CASE-MOUNTED CONTACT BREAKER

1. Assemble in the reverse order of disassembly.
2. Lubricate the cam with a light application of high temperature grease during assembly, and thereafter at every 5,000 miles.
3. Seat the advance assembly squarely and firmly on the camshaft end.
4. Adjust the point gap.

STARTING SYSTEM

Troubleshooting

If the engine doesn't start after 30 seconds of operating the starter motor, let the starter cool for no less than two minutes before operating it again.

1. If the starter motor doesn't turn at all, the trouble is either a dead battery or, more likely, a disconnected wire. Check the mounting and wiring connections of the starter first, and then check the battery and return circuits. The solenoid switch should be mounted firmly. All connections must be clean and secure for effective operation.
2. Check the battery for charge by noting the brightness of the headlamp or by using a hydrometer. If the battery is charged and the wiring is good, the problem is either the starter, the switches, or the engine itself.
3. If the battery is charged, the problem may be in the switches. This can be checked by bypassing each switch with a jumper.
4. If the engine oil viscosity is too great, or if the bearings or pistons are too tight, the engine may not turn over. If the engine can be kicked over with the normal amount of effort but the starter won't turn it over (assuming the battery is charged), the starter motor is probably faulty.

Starter Motor

REMOVAL AND INSTALLATION

Sportster

1. Disconnect the cable from the starter motor. Unbolt the clamp from the crankcase.
2. Unscrew the starter motor throughbolts from the starter shaft housing.
3. Remove the starter motor.
4. Installation is the reverse of removal.

Glide Models

1. Disconnect the cable from the starter motor. Remove the nuts securing the starter motor housing to the studs on the chain housing.
2. Remove the starter motor end support plate from the transmission.
3. It may be necessary to loosen and elevate the battery box to provide clearance. Remove the starter motor and shaft housing together.
4. Installation is the reverse of removal.

Delco-Remy Starter Motor

DISASSEMBLY

1. Remove the thru-bolts, nuts, and lockwashers. The bolt which lies nearest the field coil has a vinyl insulating sleeve which must be removed carefully.
2. Remove the commutator end frame and drive end frame. If they don't slide off, tap them gently with a soft mallet.
3. Press or tap the armature from the drive end of the frame.
4. Remove the pole shoe screws, terminal nuts, lockwashers, insulating washers, terminal screw, field coils, and pole shoes.
5. If the brushes are grounded or the holders are defective, remove the brush holders by drilling out the rivets. If done carefully, a cold chisel can be used.
6. Remove the brush springs by turning them clockwise after compressing one side with a screwdriver until the springs leave their seats.
7. Remove the insulated brush by cutting off the lead where it joins the field coil wire.

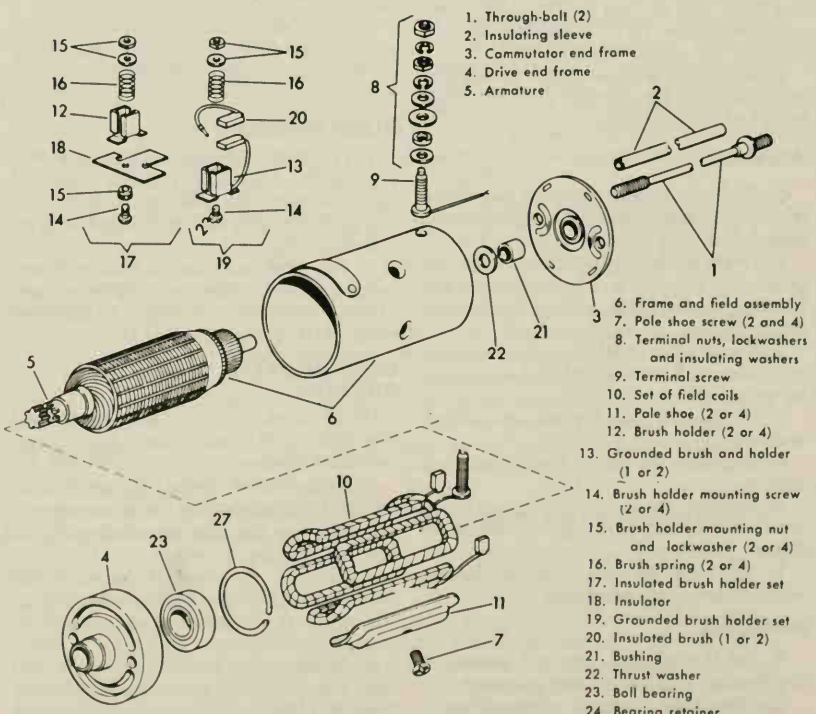
ASSEMBLY

Refer to the following section on Prestolite starter motors. Procedures are the same.

TESTING THE FRAME AND FIELD ASSEMBLY

1. Test for an open circuit with a test lamp connected to the terminal screw and insulated brush. An open circuit will keep the lamp from lighting.
2. Test for a grounded field circuit with a test lamp lead on the terminal or on each insulated field coil brush, and the other lead grounded to the frame. If the lamp lights, the circuit is grounded.
3. Check each insulated brush holder for a grounded condition by using a test lamp. Replace any for which the lamp lights.
4. Replace the field coils if a short is suspected and note whether performance is enhanced.

TESTING THE ARMATURE



1. Connect a test light or voltmeter between the commutator and armature core.
2. If the light comes on (or the meter responds), the armature coil is grounded and the armature should be replaced.

ARMATURE REPAIR

1. Place the armature in a lathe and turn down the commutator if it is worn, out of round, or if the mica insulation protrudes above the segments. This should only be done by an experienced mechanic.
2. Undercut the mica 1/32 in. with an undercutting machine or a hacksaw blade. Be sure that the mica surface is flat and even, and is kept free of dirt and copper dust.
3. Lightly sand the commutator with "00" sandpaper to ensure a smooth surface.
4. Examine the bearing, bushing, and thrust washer for damage and wear (i.e., excessive play), and replace if in doubt.
5. Information concerning armature testing may be obtained through Delco-Remy, but replacement is advised over repair.

BRUSH REPLACEMENT AND REPAIR

1. Complete replacement sets are available for brushes, grounded holders, and insulated holders. Minimum acceptable brush length is ¼ in.

Delco-Remy four-pole starter motor

2. Prepare to replace the insulated brush by cleaning the coil lead end with a file or grinder.

3. Prepare the surface for soldering with rosin flux or use a flux-based solder. Only remove varnish from the leads in the area to be soldered.

4. Solder the coil lead to the back side of the coil, taking care not to use excessive amounts of solder. Solder must never contact the armature. Overheating the brush lead will cause the solder to run onto the wire strands, making the lead inflexible.

5. When replacing the grounded brush, peen the brush holder mounting screws with a hammer so that the nuts won't vibrate loose.

Prestolite Starter Motor

DISASSEMBLY

1. Remove the thru-bolts, washers, lockwashers, and commutator end cover.

2. Insert a tube the diameter of which exceeds that of the commutator. This will keep brushes in place and allow the armature to be replaced without touching the brushes.

3. Remove the armature, drive end cover, and bearing as one assembly. The bearing may have to be pressed out.

TESTING THE FRAME AND FIELD ASSEMBLY

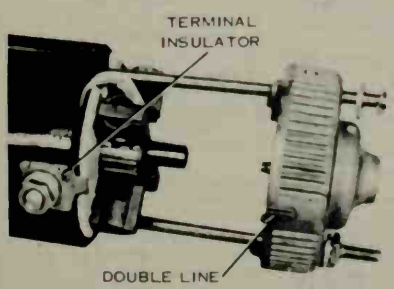
1. Coils can only be tested for an open circuit; any type of coil failure requires replacement of the frame and field assembly.

2. Touch one test lamp lead to the frame and the other to each field coil brush. The lamp should light on each brush; failure to do so indicates an open circuit.

BRUSH REPLACEMENT AND ARMATURE REPAIR

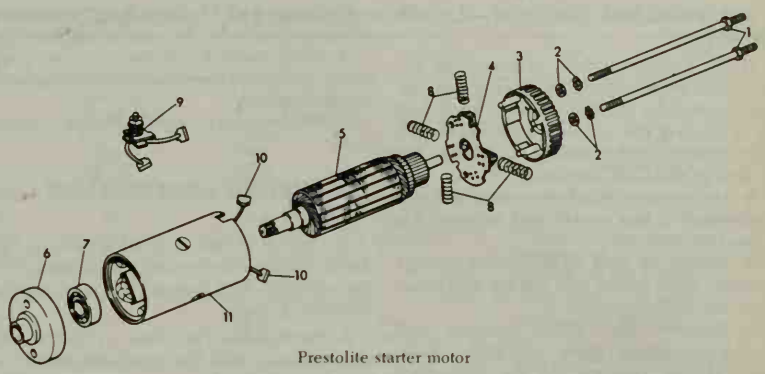
Same as for Delco-Remy starter motor.

ASSEMBLY (ALL MODELS)



1. If the brushes and springs have been released, clamps can be used to hold them in place while reinstalling the armature.

2. Align the end cover mark to the motor terminal.



3. Align the brush holder positioning notch with the motor terminal insulator.

4. Align the commutator end head with the motor terminal.

5. Install the thru-bolts, washers, and lockwashers, and mount entire unit on engine.

Hitachi Starter Motor

DISASSEMBLY

1. Remove the cable terminal nut and washers.

2. Remove the nuts and washers from the through-bolts, and take out the bolts.

3. Remove the rear cover screws. Remove the rear cover by tapping it off with a plastic mallet until a screwdriver can be inserted between the armature housing and cover and the cover pried off. Be sure the cable terminal stays in place near the housing.

4. Lift up the brush springs; remove the positive brushes completely (their leads go to the field coils); lift up the negative brushes and use the springs to trap them in their holders, clear of the commutator.

5. Remove the front cover, the armature, and thrust washer(s).

INSPECTION

1. Minimum acceptable brush length is $^{7}/_{16}$ in.

2. Check field coil insulation. If necessary, field coils are replaced along with the housing.

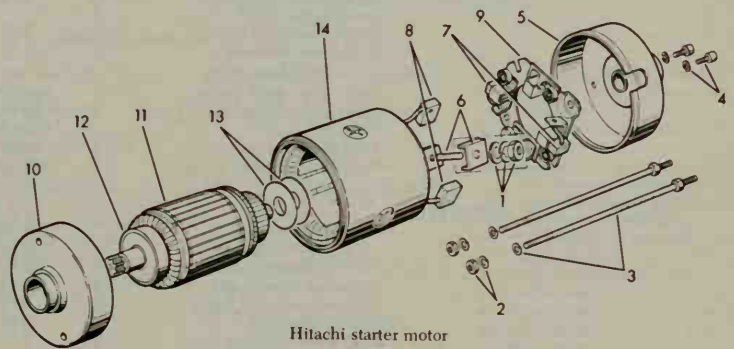
3. Check bearing for play and replace if necessary. The rear cover bushing, if defective, is replaced along with the cover itself.

4. Clean commutator surface with No. 00 sandpaper. Mica must undercut commutator segments by $^{1}/_{32}$ in.

ASSEMBLY

1. Assembly is basically the reverse of disassembly.

2. Align the mark on the housing with the notch on the front cover.



3. Be sure to align the brush holder with the rear cover screw holes.

4. Tighten through-bolts to 20–25 in. lbs.

SWITCHES

Ignition-Light Switch

This switch is centrally located in the instrument cluster on most models and has three positions plus a center-off position. One click to the right turns on the ignition, a second click to the right is for the ignition and running lights. One click to the left, from the center-off position, is for parking lights only, and, in this and the center-off position, the ignition can be locked off. The key can be removed in any position, on most models, once the ignition has been unlocked.

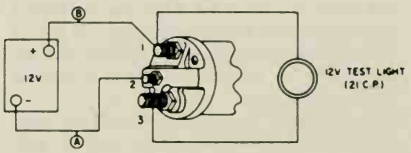
DISASSEMBLING IGNITION—LIGHT SWITCH

1. On Glide models, remove the instrument panel cover by prying out the clip located by the trip mileage knob and by removing the center screw below the speedometer. The switch must be unlocked in the "off" position.
2. Disconnect all of the wires that are connected to the switch and remove the mounting screws.
3. Grasp the end of the roller contact retainer with pliers and lift up and away from the roller contact.
4. Remove the roller contact and switch mounting plate assembly. Take note of the position of the mounting plate.
5. The reinforcing plate, contact bar holder, and rubber contact retainer can be removed from the cover by slipping it sideways until one set of tabs clears the slot in the cover, then lifting and sliding in the opposite direction.
6. Remove the switch base and lock plate from the cover. Note that the narrow end of the elongated hole and the lug on the switch cylinder are toward the lock cover hinge.
7. Remove the switch cylinder and cylinder case from the cover. Only remove the cylinder from its case if the lock is faulty. Some models have the cylinder and case as a single unit.

CLEANING AND INSPECTION

1. Wash all parts in solvent and dry them with compressed air.
2. Inspect all of the parts for excessive wear, particularly the contacting buttons and roller surfaces. Extreme wear may cause a short of the roller retainer against the lock plate.
3. Replace all worn and/or rusted parts.

ASSEMBLING IGNITION-LIGHT SWITCH



1. Apply a light coat of grease to the head of the roller retainer, lock plate, roller contact, and contact buttons on the mounting plate.
2. Reposition the lock cylinder into the housing with the tumblers in any of the four registers.
3. Insert the key, while pressing the cylinder into the housing, and turn it to the right until it stops.
4. Remove the key and complete assembly.
5. Complete assembly by using the reverse order of the disassembly procedures.

Solenoid Switch

The solenoid switches open and close the circuits electromagnetically. The 1967 Sportster and all Glide models have switches which can be repaired. There are three connections involved with the solenoid; these are: the control circuit wire, which runs from the starter button to the small terminal stud; the battery cable, which is connected to the largest stud; the starter motor cable, which runs to the large, shorter stud. Proper installation is a must because reversed cables will cause the solenoid coils to remain in circuit and will drain the battery.

When a faulty switch is suspected, tests should be made of the coil windings and the continuity of the circuit through the main switch when the contacts are closed, in the following manner:

1. Connect the positive terminal of a 12 volt battery to coil terminal 1 and the negative lead to coil terminal 2.
2. This should actuate the solenoid and an audible click should be heard. A heavy spark, or no click, indicates either an open or shorted condition and the switch must be replaced.
3. Connect a jumper wire between terminal 1 and the small solenoid terminal that connects to the starter button lead. If the solenoid is heard to operate, but the circuit to the starter motor is still incomplete, the solenoid contacts are probably burnt or eroded.

CHASSIS

WHEELS

Removal and Installation

FRONT WHEEL

Electra-Glide (Drum Brake)

1. Raise the front wheel off the ground and support the motorcycle in this position.
2. Remove the cotter pin (or clevis pin), axle nut, flat washer, bushings (if applicable), and socket screws. Loosen the slider capnuts (or pinch-bolts) and remove the axle.
3. Lift the wheel clear of the brake drum and remove it.
4. Assemble in the reverse order of disassembly.
5. Thoroughly clean the brake linings and the brake drum.
6. Make sure that the disc slips between the caliper pads on disc brake models.
7. Secure the socket screws with a suitably sized allen wrench.
8. Secure the axle nut evenly, then the slider capnuts (or pinch-bolts), after the socket screws have been tightened, to attain proper alignment. Install a new cotter (or clevis pin).
9. Adjust the brake as described in "Maintenance." Shoes must be centered in drum.

Sportster and Super Glide (Drum Brake)

1. Raise the front wheel off the ground and support the motorcycle in this position.
2. Disconnect the brake cable.
3. Remove the axle nut, lockwasher, brake anchor, shoe centering bolt, and lockwasher, then loosen the axle pinch-bolt
4. Tap the axle loose and remove it.
5. Remove the wheel and brake assembly.
6. Assemble in the reverse order of disassembly.
7. Adjust the brake as described in "Maintenance." Shoes must be centered in drum.

Electra-Glide (Disc Brake)

1. Support the front wheel off the ground.
2. Remove the axle nut cotter pin, axle nut, and washers.
3. Loosen the two fork slider cap nuts and pull out the axle. Remove the wheel.
4. Installation is the reverse of removal. Tighten the axle nut to 50 ft lbs.

FX and Sportster (Early Disc)

1. Raise the front wheel off the ground and support the motorcycle in this position.
2. Remove axle nut and axle nut lock washer. Loosen the slider capnuts. Using a soft hammer, tap the left end of the axle to loosen and start it out. Pull axle out of fork assembly.
3. Remove the front wheel assembly and speedometer drive.
4. Reassemble in the reverse order of disassembly.
5. Align the brake pads during installation so that disc slips in properly.
6. Install speedometer drive. Be sure that drive ear engages hole in wheel hub.
7. Tighten axle nut to 50 ft lbs (maximum) and tighten the two slider capnuts. This ensures correct alignment of fork sliders.

REAR WHEEL

Glide Models (Drum Brake)

1. Raise the rear wheel off the ground and support the motorcycle in this position.
2. Remove the fender support screws and raise the fender flap (if applicable).
3. Remove the rear wheel mounting screws with a suitably sized allen wrench.
4. Remove the axle nut, lockwasher, axle, and axle spacer.

NOTE: *Remove the wheel while actuating the rear brake. Brake Pedal Locking Tool (H-D Part No. 45875-58) may be used but is not necessary.*

5. Assemble in the reverse order of disassembly.
6. Drum and hub clamping surface must be thoroughly cleaned
7. Secure the wheel mounting screws tightly so that the wheel cannot work free.
8. Secure the axle nut.

Sportster (Drum Brake)

1. Raise the rear wheel off the ground and support the motorcycle in this position.
2. Remove the drive chain master link and free the chain from the rear sprocket.
3. Remove the brake rod adjusting nut, axle nut, lockwasher, and centering collar, and then loosen the axle by tapping it on the axle nut side.
4. Remove the axle and axle spacer.
5. Pull the wheel to the rear end of the frame and lift it up and out to remove.
6. Assemble in the reverse order of disassembly.
7. Adjust the brake as described in "Maintenance."

Disc Brake Models (1973 and Later)

1. Raise rear end of motorcycle off the ground and support in this position.
2. Disconnect rear chain. Remove brake anchor nut and cotter pin. Loosen castle nut.
3. Remove axle nut, lockwasher, axle, and spacer which fit between swing arm and sprocket side of wheel hub. Axle centering spacer fits into rear axle slot in swing arm. Remove wheel assembly.
4. Assemble in the reverse order of disassembly.
5. Tighten axle nut to 50 ft lbs (maximum). Adjust rear chain as described in "Maintenance."

SIDECAR WHEEL

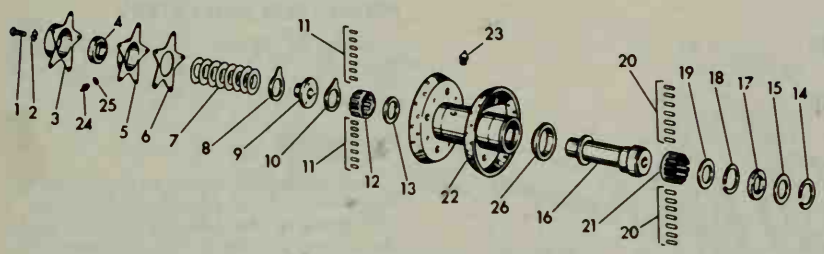
1. Raise the wheel off the ground and support the motorcycle in this position.
2. Loosen the fender front bracket and step lug, and the fender inner brace clip bracket nut.
3. Remove the axle nut, lockwasher, and brace.
4. Tilt the fender forward, taking care to leave slack in the taillight wire.
5. Remove the extension nut, axle nut, washer, and wheel and drum assembly.
6. The wheel can be detached from the drum, if desired, by removing the wheel mounting screws with a suitably sized allen wrench.
7. Assemble in the reverse order of disassembly.
8. Take care to secure the socket screws tightly so that the wheel cannot work free.

FX and Sportster (Late Disc)

1. Support the front wheel off the ground.
2. Remove the brake caliper mounting bolt, washers, and nut.
3. Remove the axle nut and washers. Loosen the slider cap nuts. Remove the axle.
4. Remove the front wheel and speedometer drive.
5. Installation is the reverse of removal. Be sure the speedometer drive ear engages the hole in the hub when installing.
6. Tighten the axle nut to 50 ft lbs., then the slider cap nuts.

WHEEL HUBS

Electric-Glide



FRONT AND REAR (1966 AND EARLIER)

Disassembly

1. Remove the wheels as described in "Wheel Removal and Installation."
2. Remove the thrust bearing cover screws, lockwashers, outer cover, cork grease retainer, bearing housing, housing gasket, bearing adjusting shims, outer thrust washer, bearing sleeve, and inner thrust washer.
3. Remove the bearing assembly and separate for reassembly.
4. Remove the roller retainer thrust washer.
5. Invert the hub and remove the outer roller retainer-spring lockring, retaining washer, hub inner sleeve. cork grease retainer, inner spring lockring, and roller bearing washer.
6. Remove the rollers, retainer, and thrust washer, and separate them for reassembly.

Inspection

1. Clean all parts other than the cork grease retainers, if they are to be reused, in a suitable solvent and blow them dry.
2. Inspect all parts for wear and replace if necessary.
3. Eliminate excessive bearing side-

play by adding 0.002 in. adjusting shims until 0.005–0.007 in. clearance is obtained between the thrust bearing sleeve and the thrust bearing outer cover. This measurement must be taken without the cork retainer present.

NOTE: *Bearing assemblies must be replaced as sets.*

4. Fit bearings to eliminate radial play by installing oversize bearing rollers until a clearance of 0.001–0.005 in. is obtained. Rollers are available in 0.0002 in. gradations from 0.001 in. undersize to 0.001 oversize.

5. Replace the snap-rings and cork retainers.

Assembly

1. Assemble in the reverse order of disassembly.

2. Install a washer under the thrust bearing housing grease fitting.

3. Lightly grease the rollers, races, and thrust washers, and inject 1 oz of grease into the hub when it is assembled. Do not overlubricate the hub, since excess grease may get in the brakes.

4. Check bearings for slight play and free-motion.

FRONT AND REAR (1967–1972)

Disassembly

1. Remove the wheels as described in "Wheel Removal and Installation."

2. Remove the wheel mounting socket screws with a suitably sized allen wrench.

3. Remove the brake drum (or brake disc flange) from the hub.

4. Remove the bearing spacer and press the drum bearing, or bearings, free from the hub side with a suitably sized drift.

5. Remove the retainer screws and retainer (late 1970 and later).

6. Remove the left-hand threaded bearing locknut with special tool (H-D Part No. 94630-67) or a suitable substitute, and remove the seal and spacer.

7. Press the hub bearing free with a suitable drift from the drum side.

Inspection

1. Check bearing for wear, rough motion, and excessive looseness of the inner and outer races and replace as necessary.

2. Inspect all of the parts for wear or damage, and replace as necessary.

3. Replace the seal if it is worn, cracked, or damaged, taking special note of the condition of the lip.

Assembly

1. Assemble in the reverse order of disassembly.

2. Pack both sides of the bearings and fill the remaining area in the hub and on the inside bearing of the drum with grease.

3. The drum and hub clamping faces must be completely clean so the wheel cannot work free.

FRONT AND REAR (1973 AND LATER)

Disassembly and Assembly

1. Remove wheel as described in "Wheel Removal and Installation."

2. Remove two lockrings. Remove washers, spacers, oil seal and bearing cones.

3. Remove bearing cups with a bearing puller. Remove spacer from hub.

4. Clean all parts in solvent. Inspect for worn or damaged parts, replace as necessary.

5. Reassemble in reverse order of disassembly.

6. Apply a liberal amount of bearing grease to all bearing cones before assembly.

7. Press oil seal into hub. Lubricate lip of oil seal and install spacer. Bearing endplay should be 0.005 in. to 0.014 in. with an axial load of 100 lbs. applied to bearing cones. If end-play is incorrect, substitute a slightly longer or shorter spacer as necessary.

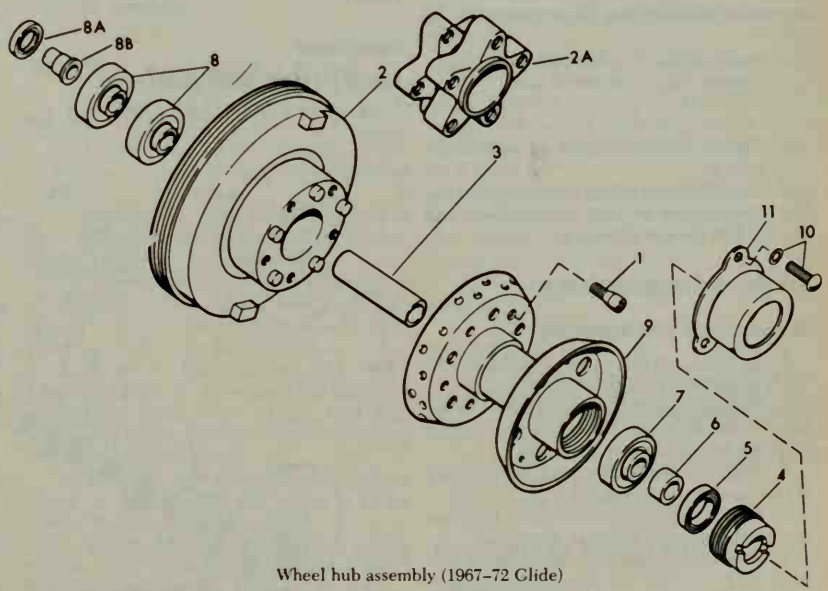
Super Glide

FRONT (1972 AND EARLIER)

Disassembly

1. Remove the wheel as described in the wheels section "Removal and Installation."

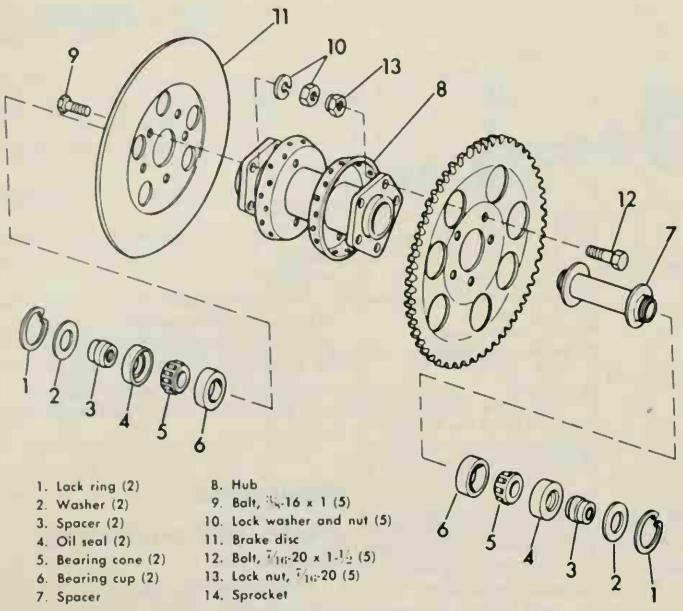
2. Pry the grease retainer free with a pointed instrument.



3. Remove the retaining ring with snap-ring pliers.

4. Gently tap the grease retainer side ball bearing into its seat in the hub. This will cause the spacer to push the other bearing out slightly. Slide the spacer back to the seated bearing.

5. Insert an appropriate sized drift through the seated bearing and drift the opposite bearing out.



Assembly

1. Press the retaining ring side bearing (shielded side out) against its seat in the hub.

2. Secure the retaining ring with snap-ring pliers.

3. Insert the bearing spacer, press the bearing against its seat in the hub, and secure the grease retainer.

FRONT (1973 AND LATER)

Disassembly and Assembly

1. Remove wheel as directed in "Wheel Removal and Installation."

2. Remove oil seals, spacer, and bearing cones. Remove bearing cups with a bearing puller. Remove spacer.

3. Remove brake disc and spacer only if they are to be replaced.

4. Clean and inspect all parts. Replace damaged or worn parts as necessary.

5. Reassemble in reverse order of disassembly.

6. Apply a liberal amount of bearing grease to all bearing cones before assembly.

7. Press oil seals into hub flush with outer surface. Lubricate lip of oil seal and install spacer. If brake disc and spacer were removed, inspect mating surfaces for flatness and reinstall. Tighten retaining bolts to 35 ft lbs.

8. Install wheel. Inspect bearing end-play, it should be between 0.005 to 0.013 in. If end-play is incorrect, substitute a slightly longer or shorter spacer as necessary.

Sportster

FRONT (1972 AND EARLIER)

Same as Super Glide (1972 and Earlier)."

FRONT (1973 AND LATER)

Same as "Super Glide (1973 and Later)."

REAR

Disassembly

1. Remove the wheel as described in the "Removal and Installation" section.

2. Remove the bearing locknut with the special tool (H-D Part No. 94630-67) or a suitable substitute. It will be necessary to break the stakings.

3. Drift the bearing oil seal and the outer spacer free from the opposite side of the hub with a suitable drift.

4. Drift the ball bearing and washer free in the above manner.

5. Remove the bearing spacer.

6. Drift the ball bearing, spacer (or spacer washer), and grease retainer as in the above manner.

Assembly

1. Press the bearing oil seal into the locknut and the outer spacer into the oil seal.

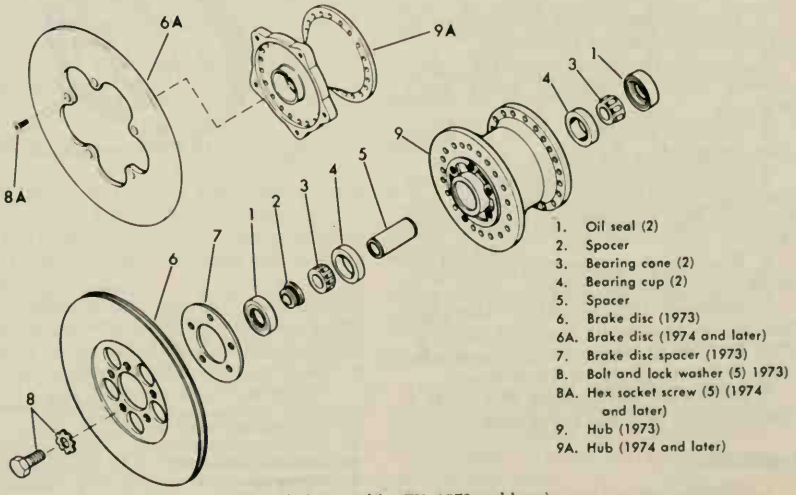
2. Secure the bearing washer, bearing, and assembled locknut to the hub. Stake the locknut in two new places.

3. Insert the bearing spacer in the hub.

4. Press the ball bearing (or unshielded bearing) until it is seated against the bearing spacer.

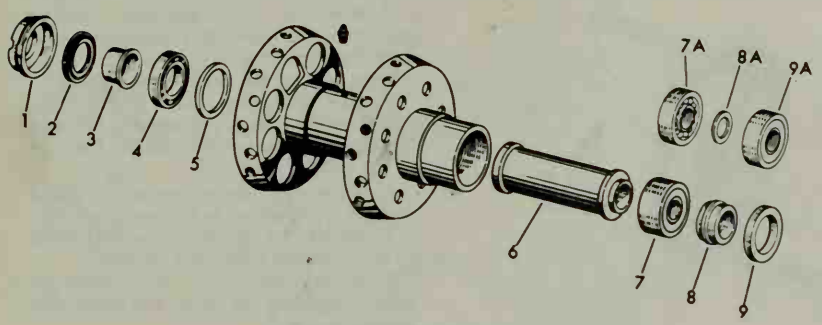
5. Insert the bearing spacer (or bearing spacer washer) and the grease retainer (or shielded ball bearing).

REAR WHEEL SPROCKET



Drum Brake Models

GLIDE MODELS



1. Remove the wheel as described in the "Replacement and Installation" section for the wheels.

2. Remove the brake drum from the wheel as described in the wheel hub section.

3. Free the sprocket from the drum by chiseling off the heads of all rivets and

dowel pins from the brake shell side and then by punching them out.

4. If the rivet holes are not worn or elongated and if the drum is still in good condition the rivet holes may be reused. If not, procede as follows:

a. Using a new sprocket as a template (guide), drill a new rivet hole from the brake shell side between the original dowel and the rivet holes. Use a No. 10 drill bit (0.1935 in. diameter) for the 3/16 in. rivets.

b. Drill another hole opposite the first one and secure both with rivets but do not head them.

c. Drill the remaining holes and remove the sprocket.

d. Smooth the drum surface around the rivet holes.

6. Using the sprocket as a template, drill new 3/16 in. dowel holes and smooth off any burrs which may have resulted. The dowel pins must be a press fit.

7. Place the drum on the center support flange of Riveting Jig (H-D Part No. 95600-33B) and carefully align the sprocket on the drum. An appropriate riveting device may be substituted. If substitute rivets are used, make sure that they will provide a strong enough bond.

8. Insert the dowel pins, then the rivets, from the brake shell side in the following manner:

a. Using a hollow driver, drive the sprocket and hub flange together by seating the dowel pins and rivets.

b. Work in opposite pairs to ensure an even seat between the sprocket and hub.

c. Flare the dowel pin and rivet ends with a punch until the heads extend 3/32 in. above the sprocket surface. Use a concave-end punch for the dowel pins and the smaller rivets, and a flat-end punch for the larger diameter rivets.

SPORTSTER

1. See "Glide Models," Steps 1–3.

2. If the original rivet holes are not worn or elliptical, they may be reused. If in poor condition, drill a new set midway between the original dowel and rivet holes.

Use the new sprocket as a template for locating holes.

3. Drill a 9/64 in. hole from the brake shell side.

4. Insert, but do not head, a rivet. Drill another hole directly opposite to the first, inserting a rivet as before.

5. Drill the remaining rivet holes.

6. Remove rivets and sprocket. Deburr the rivet holes.

7. Using the sprocket as a template, drill four new dowel pin holes (3/16 in. dia.). The dowel pins must be a press fit.

8. Position sprocket and drum on riveting jig. Insert and seat the dowel pins first. Then the rivets. Insert the dowel pins and rivets from the brake shell side.

9. Use a hollow driver and seat the dowel pins and rivets driving the sprocket and hub flange together at the same time.

10. Use a concave punch to flare the dowel pin ends. The rivet heads should extend 3/64 in. above the sprocket face.

11. Repeat the procedure for the opposite dowel pins and rivets.

DRIVE CHAIN

REMOVAL AND INSTALLATION

1. Loosen the axle housing frame clamps.

2. Loosen the axle adjusting screw locknuts and shift the axle forward about ½ in.

3. Jack up the right wheel and spin it until either side of the master link is visible through the chainguard slot.

4. Loosely connect the chain links on either side of the master link with mechanic's wire to prevent the chain from running off the sprockets.

5. Remove the master link with Chain Tool (from tool kit—H-D Part No. 95020-38), Shop Tool (H-D Part No. 95021-29) or pry the spring clip from the link with a screwdriver.

6. Attach a new chain to the present chain, or an old chain if chain is to be cleaned, with the master link.

7. Rotate the wheel forward while feeding one chain off the sprockets and the other one on.

8. Attach the loose end of the replacement to the chainguard with a piece of mechanic's wire.

9. Remove the replaced chain and connect the ends of the replacing chain. If a new chain is being mounted, secure it with a new master link, or at least use a new spring clip.

10. Secure the spring clip with Press Tool (H-D Part No. 95020-66) or pry on with a screwdriver.

11. If a second chain is not available, remove the chainguard and feed the chain off from the sprockets by rotating the rear wheel. Replace the chain by putting one end over the rear sprocket. With the transmission in First gear, crank the engine until the chain goes over mainshaft sprocket and secure it with the master link.

12. Adjust the chain as described in "Drive Chain Adjustment."

Determining Chain Wear

1. Lay the chain out on a flat surface.

2. Push the links together, a couple at a time, until all slack has been removed. Measure the overall length.

3. Pull on both ends until the chain is extended to its greatest possible length. Measure the chain again. If the overall length is greater by more than one inch, the chain is excessively worn and must be replaced.

4. This procedure can be used to measure the length of continuous-type primary chains also. Lay the chain on its side to do this and replace if the difference is greater than ⅜ in.

DRUM BRAKES

Front Brake Cable Removal and Installation

1. Remove the wheel and the outer dust cover on Glide models.

2. Remove the clevis clamp nut and clamp.

3. Free the cable from the clevis and pull it free from the upper end of the cable housing (coil).

4. Slide a new cable in from the top of the cover, applying a light coat of grease as it goes in.

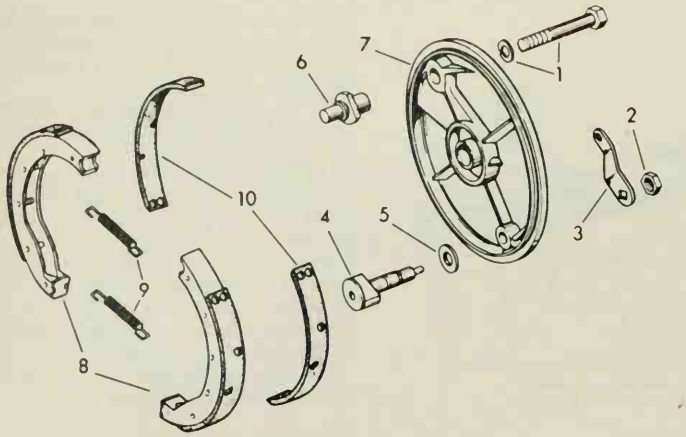
5. When installing the side slot cable ferrule in the brake lever, position the slot toward the inside, or down, on the earlier type, with the end slot.

6. Turn the adjusting sleeve clockwise to its stop.

7. Pull the cable from the lower end to remove all slack.

8. With the actuating lever in its lowest position, loop the cable around the clevis and secure it with a clevis clamp and clamp nut.

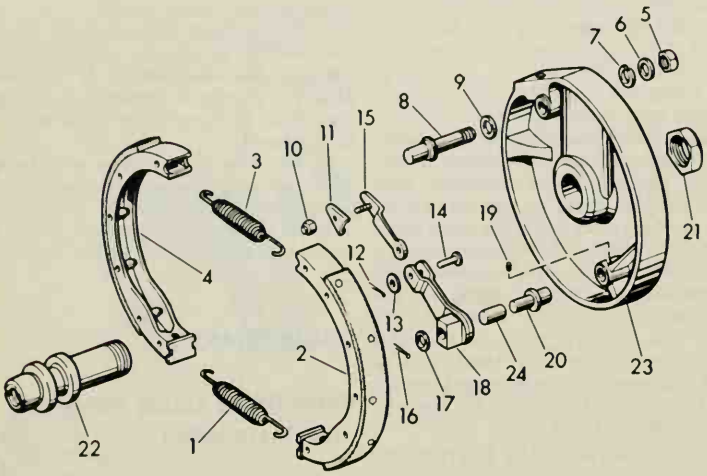
9. Replace the wheel and dust cover if applicable.



10. Adjust the brake cable.

Front Brake (Drum Brakes)

DISASSEMBLY



Sportster and Super Glide

1. Remove the wheel, with the brake drum, from the fork.

24. Cam lever bushing

2. Remove the operating shaft nut and lever.

3. Remove, as a unit, the brake shoes, springs, operating shaft, washer, and pivot stud, by tapping with a soft mallet on the operating shaft.

4. Remove the shoes and springs from the pivot stud and operating shaft.

Glide Models

1. Remove the wheel, with the brake drum, from the fork.

2. Remove the dust cover.

3. Remove the shoes and springs by lifting them out and away from the side-cover.

4. Remove the cotter pin, washer, cam lever, lever bushing, set screw, and cam lever stud.

INSPECTION

1. Examine the brake shoes, lining, drum, cam pivot, and the cam for excessive wear, glazing, and embedded particles.

2. Exposed rivets on linings will gouge the drum and must be replaced. Oil-soaked, hard, cracked, or glazed linings must be replaced. Slightly worn linings can be dressed with medium grade sandpaper.

3. Replace the linings with rivets or replace them with ready-lined shoes. Always set the rivets from one end to the other to ensure a smooth, tight fit. Bevel the end of each brake lining.

4. Lightly lubricate the pivot stud (one squirt from a standard grease gun on Sportster grease fittings).

5. Rough up the drum braking surface with emery paper.

ASSEMBLY

1. Assemble in the reverse order of disassembly.

2. Assemble the brake shoes on the operating camshaft and pivot the stud with the top return spring in place in its groove nearest the brake side plate.

3. Assemble the shoes to the side plate, taking care to register the flat side of the pivot stud correctly in the flat side of the plate.

4. Secure the lower spring in place using a screwdriver as a lever or pliers.

5. Secure the operating nut and lever to the camshaft (Sportster models).

6. Mount the wheel and brake assemblies, adjust the cable, and center the shoes.

Rear Brake

DISASSEMBLY

Sportster

1. Remove the wheel from the motorcycle.

2. Free the brake rod from the operating lever by removing the brake rod adjusting nut.

3. Remove the shaft nut and its lockwasher, operating lever, pivot stud nut and its lockwasher, and the locating block.

4. Tap with a soft mallet on operating shaft, and shoes, springs, pivot stud, operating shaft, and washer will all fall away from brake side-plate.

5. The shoes will now come free from the operating shaft and pivot stud.

Glide Models

1. Remove the wheel from the motorcycle.

2. Remove the return spring, anchor spring, and shoes from the side cover.

3. The hold-down leaf springs may now be removed.

4. After removing the cylinder screws and lockwashers, the cylinder will come off from the side-cover.

5. Pry the cylinder boots free and remove the pistons, cups, and springs.

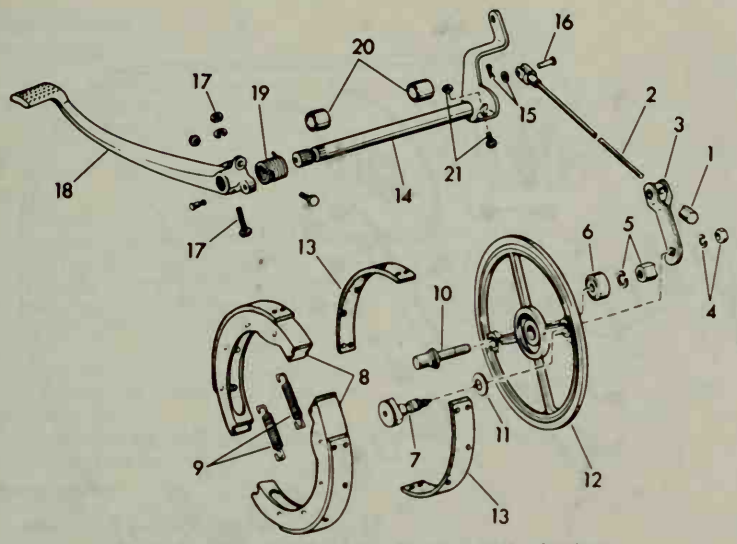
INSPECTION

1. Consult "Front Brake Inspection" for the Sportster and all other models with mechanical rear brakes.

2. Follow the same steps for hydraulic rear brakes but inspect the cylinder and side-cover for signs of leakage.

3. Do not operate the brake pedal with the shoes and springs removed from the back plate.

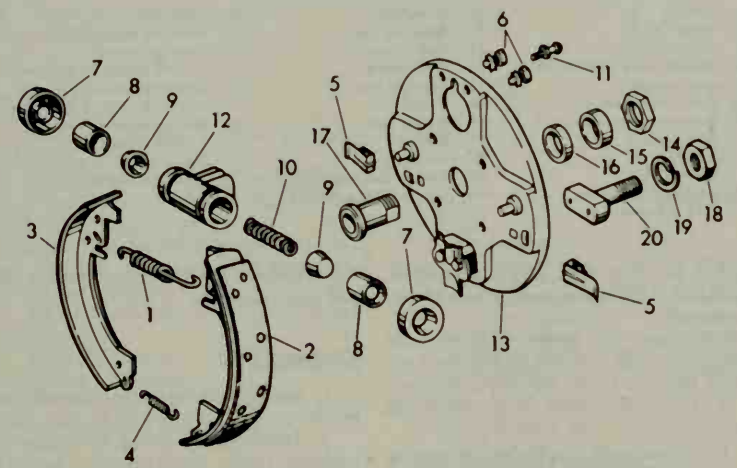
4. Remove all burrs from the cylinder and piston.



5. If the cylinder is faulty, install a repair kit. Dip the parts in brake fluid and use all of the parts provided. Never use gasoline on any hydraulic parts.

ASSEMBLY

Sportster



1. Assemble in the reverse order of disassembly.

2. Using one spring, mount the shoes on the operating shaft and pivot stud, taking care to seat the spring in its groove on the back plate.

4. Mount the locating block, pivot stud nut and lockwasher, operating lever, and the shaft nut and lockwasher on the shaft.

5. Secure the shoes with a second spring. Use a screwdriver as a lever, or pliers to install it.

6. Place the brake rod through the lever ferrule and secure it with an adjusting nut.

7. Assemble the brake and wheel on the motorcycle.

8. Adjust the adjusting rod and center the shoes.

Glide Models

1. Assemble in the reverse order of disassembly.

2. Lightly grease the hold-down leaf springs, and the area on the side plate where the shoes seat during operation.

3. Connect the shoes with the lower return spring, place the assembly on the back plate, and secure it with the upper spring, using a screwdriver as a lever or else with pliers.

4. Place the short hook in the elongated hole on the front shoe (when applicable).

5. On 1965 and later Glide models, the shoes are of different widths and the narrow shoe must be on the rear of the back plate.

6. Assemble the wheel on the motorcycle.

7. Adjust the linkage and center the shoes.

Rear Brake Cross-Shaft Mechanical Brake Models

DISASSEMBLY

1. Disconnect but do not remove the rear chain.

2. Remove the rear cylinder exhaust pipe and muffler.

3. Remove the brake rod, clevis pin, cotter pin, washer, and clevis pin from the lever arm.

4. Back off the pinch-bolt until the foot pedal lever and return spring can be slipped from the shaft.

5. Remove the shaft from the right-side of the machine.

INSPECTION

1. Inspect the shaft and the lever pedal splines, and replace them if they are damaged or worn. Excessive wear will cause the lever to slip on the shaft reducing braking accuracy.

2. Assemble the clevis pin in the rod clevis and check for wear. Replace the pin if it is worn; always replace the cotter pin.

3. Check to see if excessive clearance has developed between the bushings and shaft; replace the bushings if necessary.

4. Bushings can be drifted out from the frame by threading in a ¾–16 in. tap from the outside of each bushing.

5. Press in new bushings, install the shaft, and check to see that the shaft rotates freely.

6. Ream the bushing to the correct size of high spots developed during drifting.

ASSEMBLY

1. Replace bushings if they have been removed.

2. Insert the shaft in the frame tube.

3. Assemble the shaft arm, if it has been removed, and secure it to the brake rod clevis with the pin, washer, and cotter pin.

4. Mount and adjust the chain on the rear sprocket, and assemble the tail pipe and muffler.

5. Set the cross-shaft adjusting screw so that, when it is stopped against the frame, the cross-shaft arm is slightly behind the center of the rear fork pivot bolt. The arm must never be closer than 1½ in. to the inner recess of the transmission sprocket cover.

6. Assemble the brake pedal on the shaft so it lies slightly beneath the foot rest. Adjust the cross-shaft adjusting screw until the pedal is correctly positioned. Always adjust it so the arm moves away from the transmission cover.

7. Secure the cross-shaft bolt locknut.

8. Check the brake pedal adjustment.

DISC BRAKES

Two types of caliper are in use, here referred to as "early" and "late." The early-type caliper was used from 1972 and continues in use on FL/FLH (f&r) and FX (rear).

The early type is easily recognizable since the caliper halves are secured by four through-bolts and it has a symmetrical shape unlike that of the late caliper.

The late-type caliper is used on the front of FX and Sportster models, 1974 and later.

Bleeding

1. The brake must be bled anytime a line or cylinder is opened to remove all air.

2. Place a length of plastic tubing of appropriate size over the bleeder nipple and run the tube into a container with about one inch of brake fluid already in it so bubbles will be visible and so no air can get back in the system. Be sure there is no room for leakage around the nipple because brake fluid removes paint.

On front brakes, turn the wheel all the way to the right to get the bleeder valve nearly vertical.

3. Open the bleeder nipple by rotating it counterclockwise about ½ turn.

4. Keep the master cylinder full of fluid at all times to keep air out of the system.

5. Pump the foot pedal or hand lever slowly until no air bubbles come out of the plastic tube.

6. Fill the master cylinder to its original level.

7. Close the bleeder nipple first and then remove the plastic tube.

8. If bubbles keep coming, replace the master cylinder check valve.

9. Do not reuse brake fluid since it is hydrascopic (attracts moisture) and will become moisture-ridden from sitting in the draining container. This will cause spongy brake action.

Caliper (Early)

DISASSEMBLY

WARNING: *Hydraulic brake fluid will damage plastic, paint, and chrome surfaces.*

1. Free the hydraulic line from the hose clamp.

2. Remove the caliper bolts, washers, and outer caliper half.

3. Remove the mounting pin and inner caliper half.

4. Remove the brake pads and pad mounting pins.

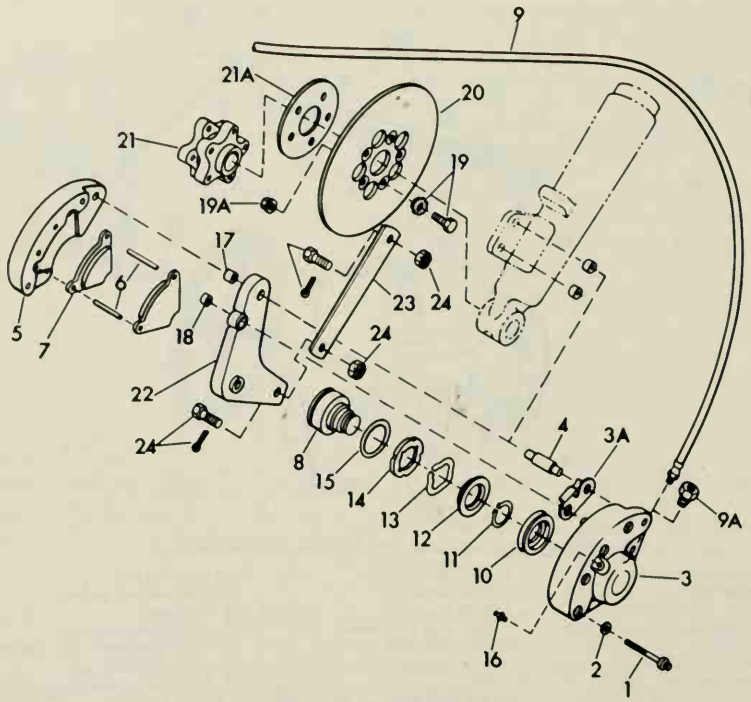
5. Inspect the brake pad friction material for excessive wear, damage, or a loose fit, and replace as a set if friction material is less than 1/16 in. thick.

6. Inspect the friction material backing plates for damage or a warped condition and replace them if they are not completely flat.

7. Check the piston retraction with a dial indicator or spin the wheel and check it for drag. The piston should retract 0.020–0.025 in. when the hand lever is released.

8. Replace the piston if fluid leaks through the seal or if the piston does not retract. Replace in the following manner:

a. Pump the hand lever until the piston moves to the end of its travel.



b. Disconnect the hydraulic line or drain the fluid into a clean glass container if the fluid is to be reused.

c. Slide the piston boot away from its groove in the piston and pull the piston free.

d. Remove the retaining ring with snap-ring pliers and slide out the backing plate, wave spring, adjusting ring, and O-ring.

9. Remove the bleeder valve.

10. Clean all of the metal parts in clean brake fluid.

24. Bolt, castle nut, & cotter pin (1973 & later)

INSPECTION

1. Replace any worn or damaged parts.

2. Replace the outer caliper half if the cylinder bore is scored or damaged.

3. Inspect the brake disc for scoring or warping and replace it if necessary. If the disc is less than 3/16 in. thick, it must be replaced as described in "Brake Disc Removal and Installation."

4. Replace the bushings in the forks slider if they are worn or damaged.

5. Replace the O-ring, adjusting ring, and retaining ring.

ASSEMBLY

1. Assemble in reverse order of disassembly.

2. Immerse the piston, retaining ring, backing plate, wave spring, adjusting ring, piston boot, and O-ring in hydraulic fluid, and assemble in bore.

3. Assemble the piston boot in the caliper bore.

4. Press the piston into the assembled bore until it firmly seats, taking care to avoid scoring the bore.

5. Assemble the bleeder valve on the caliper.

6. Assemble the brake pads and calipers to the fork.

7. Apply a graphite compound to the caliper bolts and torque them to 35 ft lbs.

8. Assemble the hydraulic line, hose clamp, screw, and lockwasher.

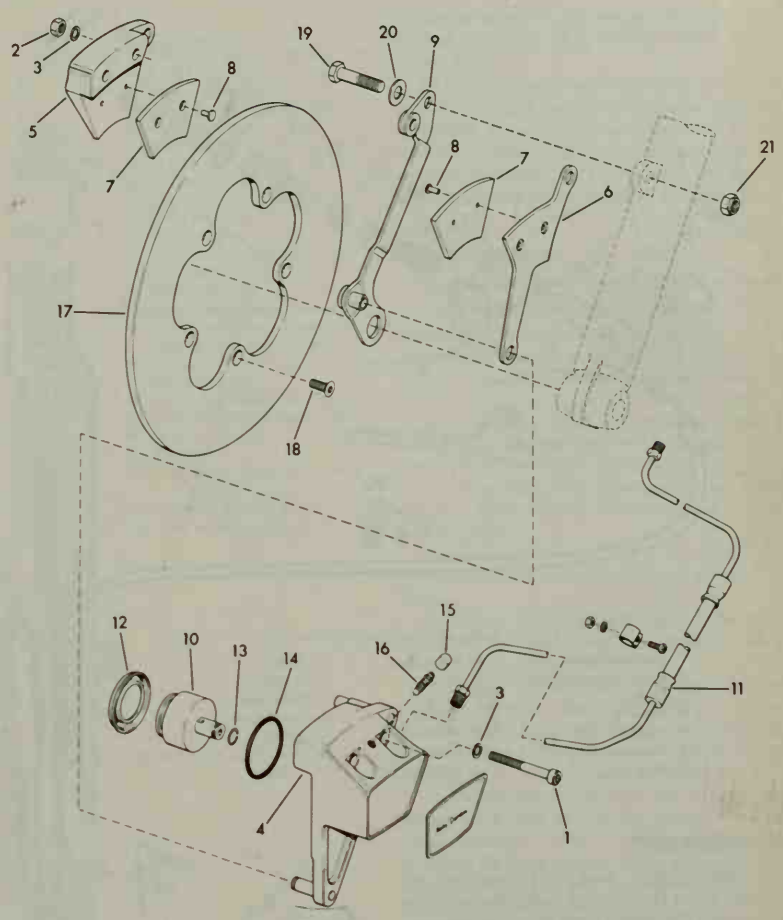
9. With the bike standing straight up, fill the reservoir with hydraulic brake fluid to the gasket level.

10. Coat the fittings with a hydraulic sealant if leaks are present (Locktite® is recommended by the factory).

11. Bleed the system as described in "Bleeding Hydraulic System" until any spongy feeling disappears.

Caliper (Late)

DISASSEMBLY



1. Wheel removal is not necessary. Remove the socket head screws which join the caliper halves and separate the halves.
2. Remove the pressure plate with brake pad.
3. Do not remove the piston from the caliper unless the seal leaks or the piston does not operate properly. Remove it, if necessary, by disconnecting and pluging the brake line, removing the rubber boot, and prying out the piston with two screwdrivers.
4. If the friction ring is damaged, remove it from the piston and replace it with a new one.
5. Remove the o-ring from the caliper. Remove the bleeder valve.

INSPECTION

1. Check the brake pads for wear. Replace them, as a set, if either is worn to the indicator groove at the bottom of the pad. Pads are replaced by drilling out the rivets with a 9/64 in. drill.
2. Check that the pressure plate is flat. If warped, replace it.
3. Check that the caliper bore is free of scoring. If damaged, replace the caliper half.
4. Clean piston and caliper half in clean brake fluid.

ASSEMBLY

1. Assembly is the reverse of disassembly.
2. Lubricate the caliper bore, piston, and o-ring with new brake fluid before inserting piston in bore.
3. Insert the piston squarely into the bore. Rotate it while tapping it into place with a plastic mallet.
4. Be sure both lips of the boot engage their grooves.
5. Push the piston all the way into the bore before assembly.
6. Be sure that all fittings are clean before assembling caliper halves.

Brake Disc (Early Type)

REMOVAL AND INSTALLATION

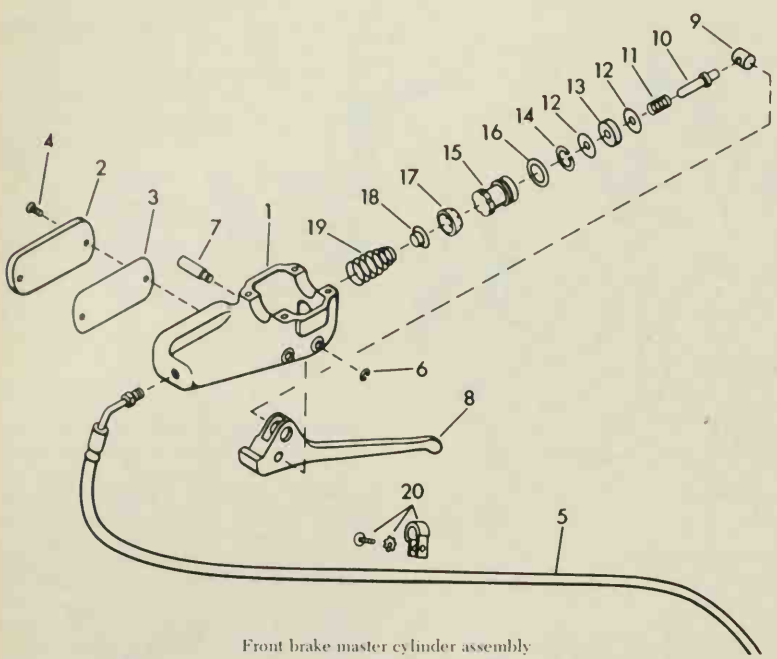
1. Remove the wheel as described in the "Removal and Installation" section.
2. Remove the disc securing bolts and lockwashers.
3. Replace the disc if it is worn to 0.188 in., or less, or if it is warped more than 1/32 in.
4. Replace the brake disc flange if it is damaged.
5. Reassemble using new lockwashers and torque to 35 ft lbs.
6. Assemble the wheel on motorcycle.

Brake Disc (Late Type)

Procedures are the same as described for the early type disc, except that the disc is secured by five screws instead of bolts. On installation, tighten the screws to 10 ft lbs.

Front Master Cylinder

DISASSEMBLY AND INSPECTION



1. Remove the cover securing screws, cover, and gasket.
2. Disconnect the hydraulic line at the caliper and drain it into a clean glass container if the fluid is to be reused.
3. Disconnect the stoplight wires and remove the handlebar switch assembly.
4. Remove the pivot pin, retaining ring, and pin.
5. Remove the lever, pin, plunger, spring, washers, dust wiper, and retaining ring.
6. Pull the piston, O-ring, piston cup, spring cup, and spring until they are free of the master cylinder.
7. Replace the piston cup and O-ring if they are worn, soft, or swollen.
8. Replace the cylinder walls if they are scratched or grooved.
9. Replace the gasket if it is leaky.
10. Blow the master cylinder vent hole clear.

ASSEMBLY

1. Assemble in the reverse order of disassembly.
2. Use all components of the repair kit if such a kit is to be used.
3. Immerse all internal parts in hydraulic fluid before assembly.
4. Lightly grease the pivot pin and plunger pin before reassembly.
5. Check to see that the relief port in the master cylinder is open when the lever is released.
6. Fill the reservoir to the gasket level with brake fluid.
7. Bleed the system as described in "Bleeding Hydraulic Brake System."
8. Install the gasket with the flat side down and secure the cover.

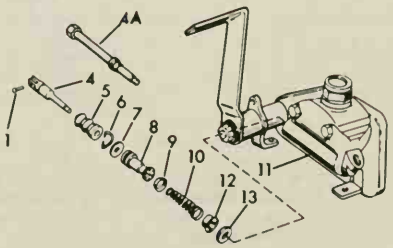
DISASSEMBLY



1. The piston assembly can be removed from the master cylinder without removing the body from the motorcycle.
2. Remove the rear brake rod clevis pin.
3. Pull out the plunger. Remove the boot, stop wire, stop washer, piston assembly, cup, spring, valve and valve seat (the valve and valve seat are used on 1972 and earlier models only).

INSPECTION

1. Check the rubber parts for damage, cracks, a swollen condition, etc.
2. Check the cylinder walls for scoring.

ASSEMBLY

1. Reverse the disassembly procedure. Lubricate all parts with new brake fluid before assembly.

FRONT FORK

Fork Slider and Tube Removal

ELECTRA-GLIDE

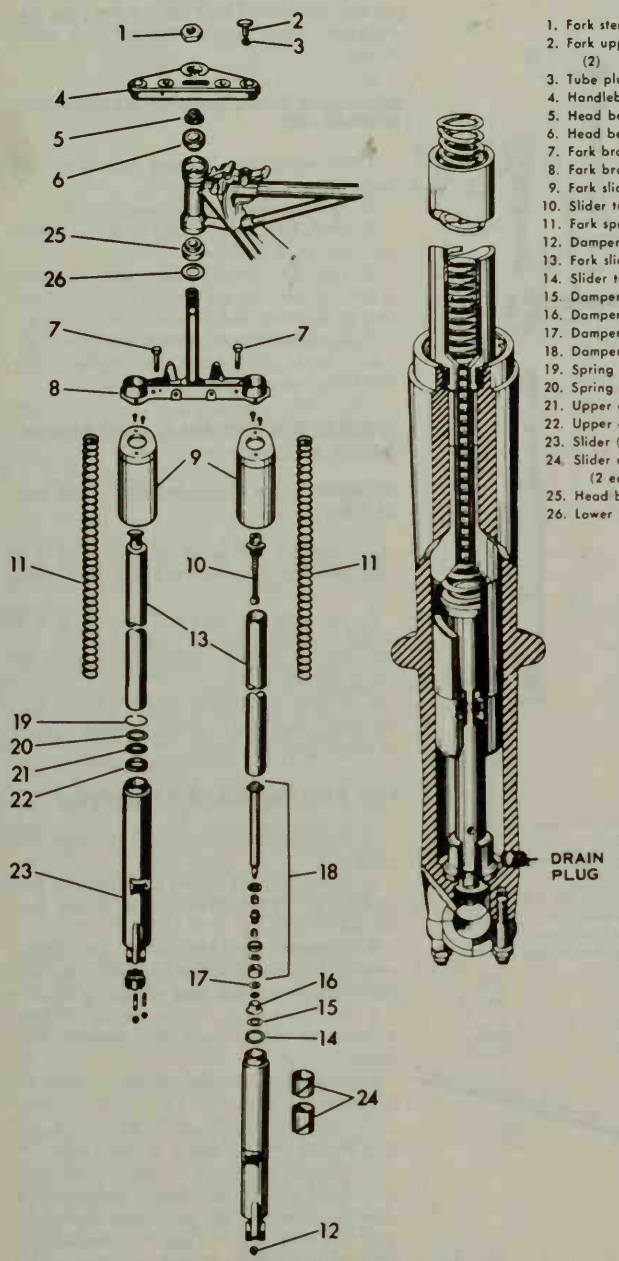
1. Remove the front wheel as described in the wheels' "Removal and Installation" section.
2. Remove the brake cable clip from the front fender.
3. Remove the axle sleeve nut, pivot stud nut, and brake side-cover and shoe assembly along with the axle sleeve, from the forks.
4. Remove the front fender.
5. Loosen but do not remove the front fork bracket clamping studs.
6. Remove the upper bracket bolts, oil seals, and fork slider and slider tube assemblies from the bottom of the slider covers.

Preliminary Disassembly

1. Remove the headlight cowlings and headlamp.
2. Disconnect all headlight and handle-bar wires at the terminal.
3. Disconnect the throttle and spark cables at the carburetor and the contact breaker.
4. Remove the handlebars.

Disassembly

NON-ADJUSTABLE



1. Remove the fork stem nut, nut lock (if applicable), upper bracket bolts, oil seal, upper bracket cover (if applicable), and handlebar and fork bracket.
2. Using Lock Nut Wrench (H-D Part No. 96219-50) or a suitable substitute, remove the head bearing nut, lift the upper bearing free, and pull the fork free from the bottom of the steering head.
3. Loosen, but do not remove, the fork bracket clamping studs and slip the fork bracket and slider cover assembly free of the fork tubes.
4. Remove the slider tube plugs, drain the oil, and remove the fork springs.
5. Remove the damper valve stud locknut and free the slider tube from the slider.
6. Remove the slider tube snap-ring with snap-ring pliers. Remove the damper tube lower bushing, damper tube bushing gasket, and damper valve stud gasket. Discard and replace all parts other than the tube assembly.

ADJUSTABLE

1. Remove the steering damper adjusting screw, spring cover, spider spring, upper pressure disc, friction washer, anchor plate, friction washer, and lower pressure disc by prying all parts loose when necessary.
2. Remove the fork stem nut, upper bracket bolts and washers, bracket cover and bracket.
3. Using Lock Nut Wrench (H-D Part No. 96219-50) or a suitable substitute, remove the head bearing nut, lift the upper head bearing free, and pull the fork free from the bottom of the steering head.
4. Remove the slider tube plugs.
5. Loosen but do not remove the bracket clamping studs.
6. Continue as described for "Non-Adjustable Glide Models."

Inspection

1. Clean all of the parts in a suitable solvent and blow them dry.
2. Inspect the slider tubes and slider for scratches, grooves, wear, and damage, and replace if necessary. Remove minor faults with a fine oil stone or emery paper.
3. Inspect the valve tube assembly components for pitting, rust, wear, and damage, and replace if necessary.
4. Inspect the slider tube plugs for loose cups or damaged springs and replace if necessary. Oil slots in the cups must be arranged on alternate sides.
5. Inspect the steering head bearings and races for pitting, rough motion, wear,

or damage, and replace in sets whenever necessary.

6. Bearing races can be drifted free with a suitable drift after the head cups are removed. Replace by pressing new races into the head cup and then pressing both into the head frame.

7. Remove both fork slider bushings, if worn, pitted, or damaged, by installing Fork Slider Bushing Puller (H-D Part No. 96255-50) or a suitable substitute. Oil the tool's threads and washer to ease removal. The bushing may be split with a chisel to remove it if care is taken not to damage the slider.

8. Install the new fork slider bushings with Fork Slider Bushing Driver and Guide (H-D Part No. 96285-50) or a suitable drift, or else use a piece of pipe with the slide secured in a copper or wood-jawed vise. If the proper bushing driver is not available, mark the tube where the bushings were originally as an aid in replacing them correctly. Lubricate the bushing and the tube to aid installation. The lower bushing should seat at a position where the second groove of the driver is aligned with the top of the guide. The upper bushing should be 1/16 in. below the oil seal counterbore.

9. Ream the bushing with Fork Slider Bushing Reamer and Pilots (H-D Part No. 96300-50) or a suitable substitute. Using the long pilot as a guide in the lower bushing, ream the upper bushing by slowly placing the reamer in position while rotating it clockwise. Always continued to rotate the reamer while withdrawing it.

10. Ream the lower bushing with the small pilot as a guide in the same manner as for the upper bushing. Take care not to mar the upper bushing while passing the reamer through it. Pilots can be made from suitably sized lengths of pipe.

Assembly

NON-ADJUSTABLE

1. Install a new upper oil seal and felt washer in a thoroughly cleaned slider. The oil seal may be seated gently in its counterbore with a mallet and Drive (H-D Part No. 96250-50) or a suitable substitute.

2. Install a new spring ring washer and a new spring ring with its gap over the slider top water drain hole.

3. Assemble the damper valve, new upper gasket, lower bushing, and a new lower gasket.

4. Secure a length of 1 in. steel rod vertically in a vise with 13½ in. above the jaws.

5. Place the inverted slider tube over the steel rod and drop the damper valve assembly in upside down.

6. Secure the slider snap-ring in the slider tube notch and check the clearance between the ring and the lower bushing. Insert shims if they are necessary to bring clearance to a maximum of 0.004 in.

7. Slide the slider over the lubricated slider tube and secure the damper valve stud locknut. Check slider motion for binding or drag. Loosen the locknut and rotate the slider 180 degrees before securing it to eliminate binding.

8. Install the assembled fork bracket and slider covers over the slider tubes so 5/16 in. of tube extends above the top of the bracket and tighten the bracket clamping studs.

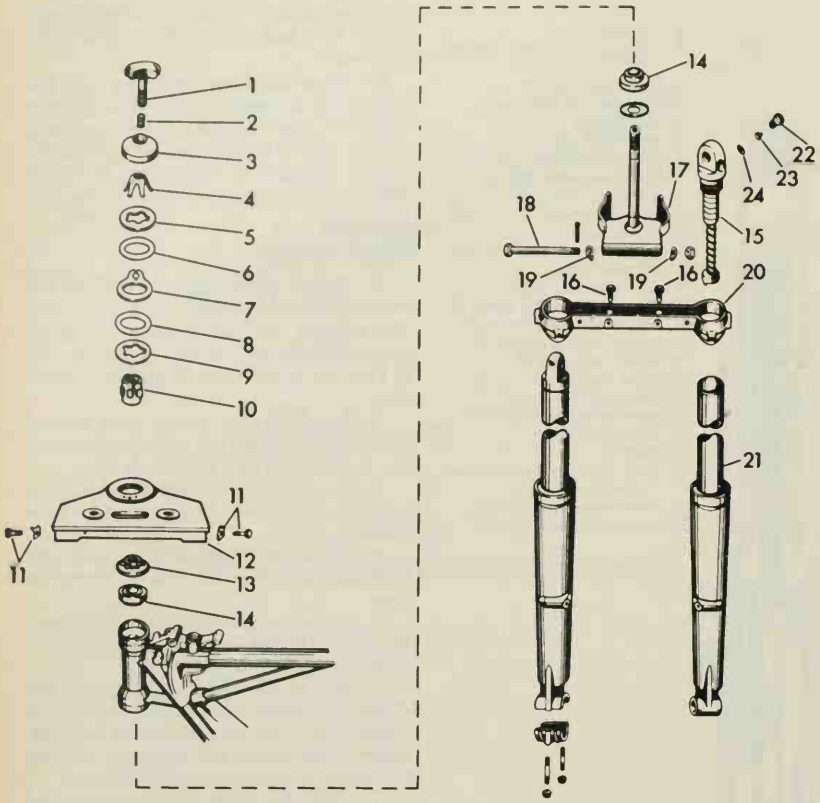
9. Fill each tube with Harley-Davidson Fork Oil (oil may be experimented with freely as long as specified quantities are conformed to) or hydraulic fluid, then install the fork springs and secure the slider tube plugs.

10. Secure the lower head bearing guard and a well-packed head bearing on the stem. Install the stem into the steering head.

11. Install a well-packed upper head bearing and secure the head bearing nut until there is slight bearing draw when the head is turned. Back off the nut until the motion is smooth.

12. Install and secure the fork bracket, bracket cover, and slider tube plugs.

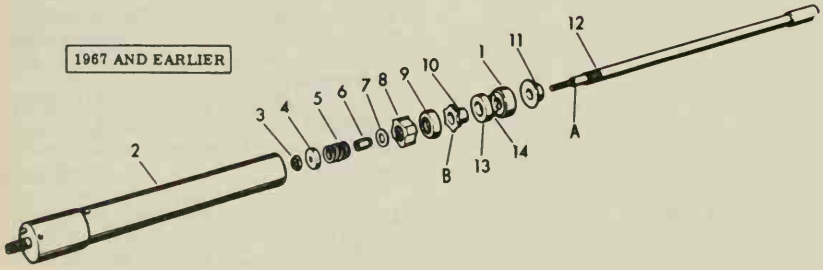
13. Loosen the bracket clamping studs and rotate the slider tubes until the tube plug flat sides are to the sides of the forks.



14. Secure the fork stem nut, bracket clamping studs, tube plug oil seals, upper bracket bolts, and handlebar.

15. Complete assembly in the reverse order of disassembly.

ADJUSTABLE



1. Consult "Non-Adjustable Front Fork Assembly."

2. Place the slider tubes in the fork bracket with tubes 5 1/16 in. above the top

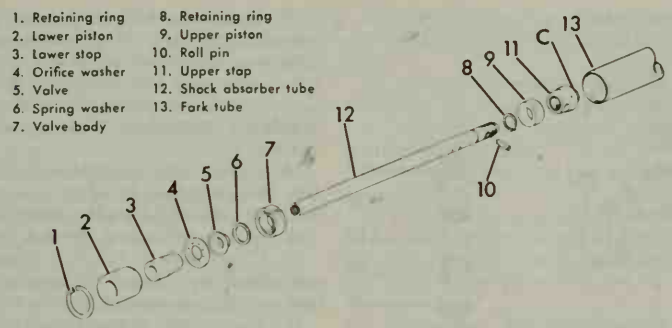
ADJUSTING ADJUSTABLE FRONT FORK FOR SIDECAR USE

1. Remove the bracket bolt nut and lockwashers.
2. Loosen the upper bracket bolts.
3. Pull the fork tubes forward until movement is detected.
4. Replace the bracket bolt washers with the pin seated in the bracket boss slot and secure the bracket bolt and nut.
5. To resume solo riding, push the fork tubes back and adjust the washer pins until they point backward.

SPORTSTER (TO 1974) AND SUPER GLIDE MODELS

Breather Valve Replacement (1972 and Earlier)



1. Remove the headlight housing if it interferes with removing the fork tube cap.
2. Remove the cap and secure it in a wood or copper-jawed vise.
3. Remove the breather valve by breaking the stakings.
4. Apply a suitable sealer when reassembling and stake in the breather valve in three new positions.

Fork Boot Replacement (Sportster)

1. Pull the boot free from the upper retainer.
2. Free the fork slider assembly as described in "Fork Slider and Tubes Removal."
3. Remove the fork vent and plain screws and loosen, but do not remove, the retainer, gasket, and retaining disc.
4. Pry the lower retainer lip to remove it from the slider and then remove the boot.
5. Assemble in the reverse order of disassembly.
6. Replace the fork slider bushings first if this is to be done at this time.
7. Secure the upper retainers by sliding them up to the slider counterbore then by inserting the pilot end of the Oil Seal Driver (H-D Part No. 96310-55) through the retainer and into the upper slider bushings. Gently tap the retainer until it is seated. A suitably sized piece of pipe can be used as a drift if the factory tool is not available.

Fork Disassembly

1. Remove the front wheel and brake assembly as described in the "Removal and Installation" for the wheels.
2. Remove the front fender, headlight cowling, and fork tube caps.
3. Loosen, but do not remove, the fork pinch-bolts and free the fork boot from the upper retainer.
4. Slide the fork leg assemblies free from the bottom.
5. Remove the piston rod (or spring) retainer with Wrench (H-D Part No. 94694-52) (on 1972 and earlier models) or a suitable substitute. Models earlier than

1973 and later FX, Sportster 1973–1974 front shock absorber

1968 require compressing the fork spring, securing the top of the shock absorber with vise grips, and then removing the piston rod retainer.

6. Remove the fork spring and drain plug, and allow the hydraulic fluid or fork oil to drain into a suitable container. Keep hydraulic fluid away from painted surfaces since it can cause corrosive damage.

7. Invert the assembly and remove the tube end bolt and washer by securing the slot in the top of the shock absorber tube with a screwdriver and then turning the end bolt. The shocks will come free on 1967 and earlier models. On 1973 and later models use Socket (H-D Part No. 94556-73) or suitable substitute, with extension on the upper end of shock absorber tube cap to keep it from turning.

8. Free the slider front fork tube and shock absorber assembly.

9. Remove the piston stop bushing with Wrench (H-D Part No. 94691-52) or a suitable substitute and remove from shock absorber tube. Remove the piston rod nut to dismantle the piston rod assembly.

10. Remove the shock absorber retaining ring with snap-ring pliers and slide the lower valve body, washer, upper body, spring (1971 and later), tube, piston, retaining ring, and piston on 1968 and later models. On 1973 and later models, disassemble the shock absorber as follows: Remove retaining ring from fork tube with snap-ring pliers and remove lower piston, lower stop, orifice washer, valve, spring washer, valve body and upper retaining ring. Disassemble upper stop by removing roll pin from shock absorber tube.

11. Remove the headlight assembly and disconnect the speedometer cable at the speedometer head.

12. Remove the stem sleeve end nut and loosen, but do not remove, the upper bracket pinch-bolt.

13. Remove the handlebar and upper fork bracket assembly and lay it aside. It is not necessary to disconnect the cables or wires as long as they do not bend sharply.

14. Remove the upper bracket spacer, stem sleeve, stem and bracket assembly, upper and lower bearing cones and bearings (and separate for reassembly), and head cups (if necessary). Head cups are easily removed by drifting from the opposite end with a suitable drift.

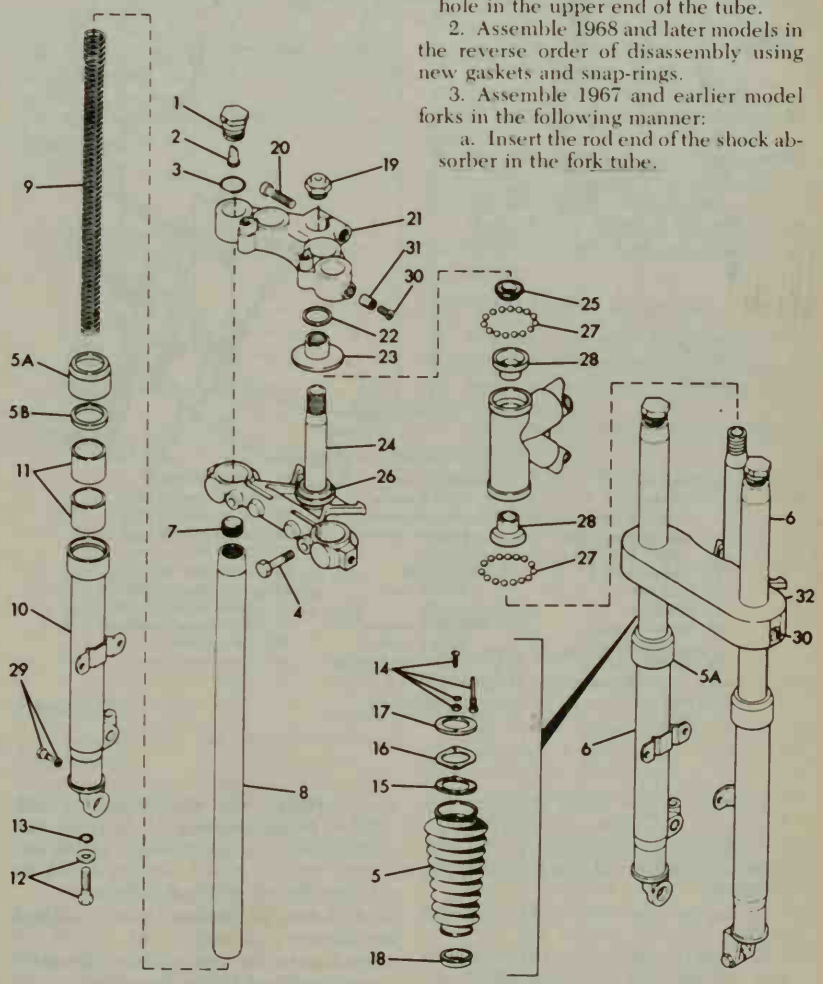
INSPECTION

1. Consult the previous section.

ASSEMBLY

1. Assemble 1967 and earlier models in the following manner:

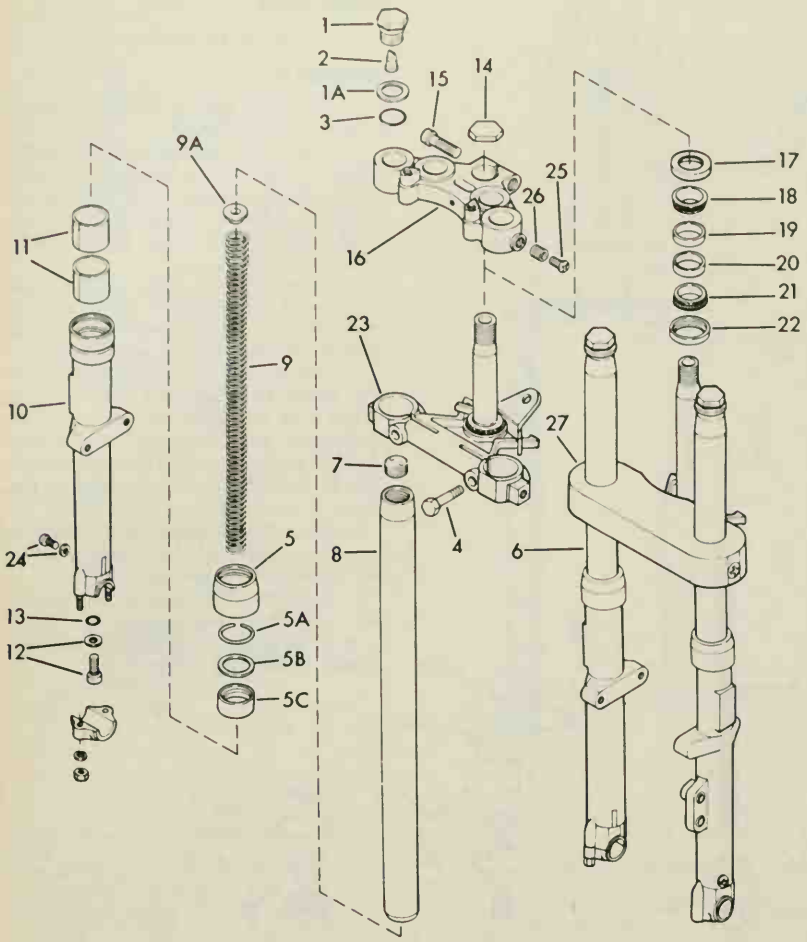
a. Assemble the piston rod guide, piston collar, spring, bushing, and stop nut on the piston rod, with the stop nut face (b) 0.550 in. from the collar (a). Stake around the center of the nut in four new places.



b. Assemble the piston valve, piston, recoil valve washer, piston spacer, valve spring, valve spring retainer, and piston rod nut onto the piston rod.

c. Secure the piston stop bushing in the shock absorber tube with Wrench (H-D Part No. 94691-52) or a suitable substitute, until the top of the bushing is flush with the end of the tube. Stake the bushing by punching through the hole in the upper end of the tube.

2. Assemble 1968 and later models in the reverse order of disassembly using new gaskets and snap-rings.



3. Assemble 1967 and earlier model forks in the following manner:

a. Insert the rod end of the shock absorber in the fork tube.

6. Install the fork stem and bracket assembly and secure it with a stem sleeve until bearing motion is smooth and free and all excessive play has been taken up.

7. Install the upper bracket spacer, handlebar assembly, and upper fork bracket.

8. Install both assembled fork slides into the mounting brackets and secure the tube caps and then the pinch-bolts.

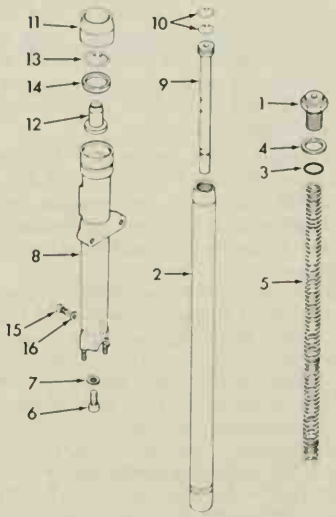
9. Count and secure the fork bolts.

10. Check fork motion for smoothness and adjust the sleeve if necessary. All side-ways shake should be removed.

11. Secure the upper bracket pinch-bolt and nut, and stem the sleeve end.

SPORTSTER (1975 AND LATER)

DISASSEMBLY



1. Remove the front wheel, brake caliper, fender, and headlight bracket.

2. Remove the two cover screws and slide the cover up out of the way to expose the lower bracket.

3. Loosen the lower bracket pinch bolts. Loosen the upper bracket screws.

4. Remove the instruments. Unscrew the tube caps. Pull out the fork legs and drain off the oil.

5. Remove the o-ring from the tube cap, if damaged.

b. Place a new shock absorber gasket on the end screw and dowel pin.

c. Assemble the slider on the fork tube so the tube end screw registers in the slider.

d. Secure the tube end nut and washer.

e. Pour in the correct quantity of fork oil over the top of the shock absorber rod and into the tube.

f. Insert the fork spring.

g. Screw a 5/16 x 24 thread rod (i.e., brake rod) into the end of the shock absorber rod, compress the spring, and grip the flat portions of the rod with vise grips. Remove the threaded rod.

h. Secure the piston rod retainer and remove the grips.

i. Stake the retainer threads through the hole at the top of the absorber rod.

j. Secure the retainer in the fork tube using Wrench (H-D Part No. 94694-52), or a suitable substitute, until the top of the retainer is 9/16 in. below the top of the fork tube.

4. Assemble 1968 and later models in the following manner:

a. Insert the fork tube and shock absorber assembly into the slider.

b. Hold the slotted top of the shock absorber rod with a screwdriver and secure a new O-ring and the tube end bolt and washer.

c. Insert a spring retainer 3/4 in. below the surface of the fork tube top using Wrench (H-D Part No. 94694-52) or a suitable substitute.

5. Secure the steering head cups, ball bearings, and bearing cones. Bearing cones must be heavily greased.

6. Remove the allen bolt from the bottom of the fork slider.

7. Pull the fork slider from the fork tube. Take the shock absorber tube out of the fork tube. Remove the wear rings from the shock absorber, if necessary.

8. Remove the fork boot. Remove the damper tube sleeve from the slider, pulling it carefully past the seal.

9. Remove the slider seal, if necessary, by first removing the lock ring and

prying the seal out. Use new seals if the old ones are removed. The slider may be heated gently to facilitate seal removal.

10. To remove the fork stem and bracket assembly, disconnect the wiring from the panel. Remove the handlebar clamp cover.

11. Remove the headlight and bracket.

12. Remove the fork stem sleeve end nut and loosen the pinch bolt. Remove upper bracket and handlebars from motorcycle.

13. Remove the washer and fork stem sleeve. Free the fork stem and bracket, carefully lowering it from the machine.

INSPECTION

1. New slider seals must be used if the old ones were removed.

2. Check the condition of all o-rings and replace as necessary.

3. Check wear ring condition and replace if damaged or worn.

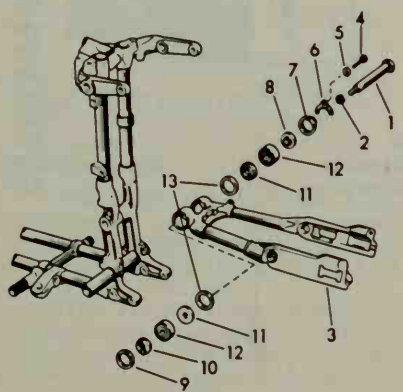
4. Check that the fork springs are of equal length and not excessively compressed.

5. Check that the oil passage in the lower end of the fork tube is clear.

6. Check condition of steering stem balls and replace balls and races if the balls are rusted or pitted, or the races are indented or worn.

There are 14 balls in each race.

ASSEMBLY



1. Lubricate the bearings and races. Tighten the stem sleeve until movement is smooth and free, but not so free that there is any play.

2. The remainder of the procedure is the reverse of disassembly.

SWING ARM

Disassembly

1. Remove the rear wheel as described in the "Removal and Installation" section for the wheels.

2. Remove the rear brake assembly and linkage as described in the brake section.

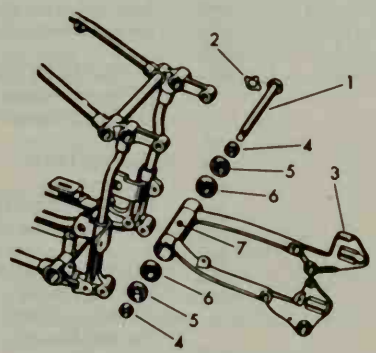
3. Remove the rear shock absorbers as described in "Rear Shock Absorbers."

4. Remove the exhaust pipe and muffler (if necessary).

5. Remove the pivot bolt and rear fork assembly.

6. Remove the bearing screw, washer, lockwasher, right locknut, and outer spacer. Use a punch to remove the left bearing locknut and pivot bolt nut on Sportster models.

7. Press the bearing inner spacer, bearing, and bearing shield from each side of the fork on Sportster models.



8. Press the bearing spacer, seal, and bearing from each side of the fork (Glide models).

Inspection

1. Clean all parts in a suitable solvent and blow them dry.

2. Inspect all parts for wear, pitting, rough bearing motion, or damage, and replace as necessary.

3. Measure the swing arm for correct dimensions.

Glide models swing arm assembly

1. Pivot bolt
2. Pivot bolt lock washer
3. Rear fork
4. Pivot bearing spacer (2)
5. Bearing seal
6. Bearing
7. Grease fitting

Assembly

1. Assemble in the reverse order of disassembly.

2. Grease the bearings thoroughly. This must be done every 10,000 miles on Sportsters or it must be greased through the fitting every 2,000 miles on Glide models.

3. Press the bearing shield into the fork from the outside until it is flush with the inside. Insert the bearing with the wide side of the race facing out. Assemble and secure the right bearing locknut and then back it off one full turn. Assemble the pivot bolt nut, then secure the left locknut and stake it in three new places (Sportster models).

4. Apply grease to the bearing seals in the groove between the sealing lips and secure the seals and spacers (Glide models).

5. Preload the bearings in the following manner:

a. Assemble the pivot bolt.

b. Weigh the extreme rear end of the fork in a horizontal position, with a spring scale, and note the reading.

c. Tighten the pivot bolt (Sportster) or the right locknut (Glide models) until bearing drag is increased by one or two pounds above the original reading.

6. Complete reassembly in the reverse order of disassembly.

REAR SHOCK ABSORBERS

Disassembly

1966 AND EARLIER MODELS

1. Remove the cover clamp, top cover mounting stud nuts, stud cover, washer, and rubber bushing.

2. Remove the shock from the mounting studs.

3. Compress the spring until the lower mounting eye can be rotated 90° then remove the shock from the tool (if used).

4. Remove the cam support.

5. Strike the lower mounting eye sharply to free the bumper from the cover flange.

6. Remove the cover and disassemble the lower cam, rotating cam, cam sleeve, dirt seal, and spacer washers.

7. Remove the bumper by extending the absorber piston shaft and the springing bumper.

1967 AND LATER MODELS

1. Remove the mounting stud nuts, upper stud cover, and cup washers.

2. Remove the shock absorber from the mounting studs.

3. Press the stud rubber bushings from the mounting eyes.

4. Remove the retaining ring.

5. Compress the spring until the split key can be removed.

6. Remove the compression tool (if used) and disassemble the remaining items.

Assembly

1966 AND EARLIER MODELS

1. Lightly grease the cam sleeve and cam surface of the adjusting cam.

2. Secure the roller pin in the lower cam and place it on the cam support with the pin and pin slot aligned.

3. Extend the piston rod and assemble the bumper.

4. Assemble the spring in the cover, then the shock in the spring, and strike the upper mounting eye to secure the bumper in the cover flange.

5. Slip the spacer and seal washers into the cover and complete assembly in the reverse order of disassembly.

6. Compress the spring and rotate the lower mounting eye 90° to secure it in the cam support notch.

1967 AND LATER MODELS

1. Lightly grease the cam surfaces.

2. Assemble in the reverse order of disassembly taking care to align the cam faces.

3. Compress the springs and insert the keys and retaining ring (if applicable).

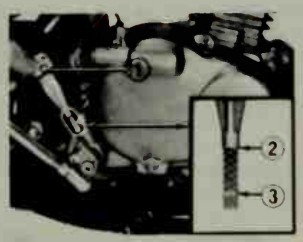
MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*



OIL CHANGES AND LUBRICATION

Checking Oil

On all models the oil level is checked by means of the dipstick incorporated into the filler cap. The filler cap is located in the right crankcase cover. To check the oil:

1. Start the engine and allow it to warm up for a few minutes.
2. Hold the motorcycle upright on level ground, remove the dipstick and wipe it clean.
3. Reinsert the dipstick, allowing the dipstick cap to rest on the top of the threads of its hole. The oil level should be between the maximum and minimum marks on the dipstick.

If the level is below the minimum mark on the dipstick, add enough oil through the hole to bring the level up to the maximum mark.

Engine oil level must be maintained between the upper (2) and lower (3) dipstick level marks

Changing Oil

1. Change the engine oil every 1,500 miles, or on machines without a speedometer, every 30 operating days or every 3 months. Use high detergent motor oil service rated "SE" only.

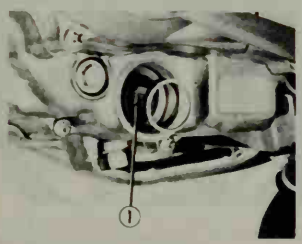
NOTE: *The oil change interval is based on normal operating conditions. If the motorcycle is used under severe conditions (i.e., racing, high-speed operation, stop-and-go riding, dusty conditions, operation in cold weather, etc.), changes should be made more frequently. This is also true if the machine is used infrequently especially during winter months.*

2. Run the engine until it is at normal operating temperature. Oil must always be changed when the engine is warm.
3. Remove the dipstick, and place a pan beneath the engine to catch the oil. Remove the drain plug and allow the oil to drain for several minutes. Kick the engine over a few times with the kickstarter to remove any oil remaining in the delivery system.
4. Replace the drain plug and tighten it securely.
5. Remove and clean the filter, if applicable, as outlined below.
6. Fill the sump with the correct amount and grade of oil. Refer to the charts at the end of this section. Run the engine for a minute or so, then shut it off and let it sit for one minute and check the oil level; add oil as necessary until the level is correct.

NOTE: *The use of oil additives is not recommended, as they may cause clutch slippage.*

Oil Filter

Two types of oil filter are used: a filter screen and a centrifugal filter. The centrifugal oil filter is located on the right-side of the crankshaft on the XR75 and 100/125 cc machines, or in the clutch on other models.



50–90 cc models have the filter screen in the crankcase under the right crankcase cover, while on the 100/125 cc bikes, the filter screen is beneath a cap on the left-side of the crankcase sump.

On 100/125 cc models, the filter screen is easily accessible, and should therefore be cleaned at every oil change. The screen on other models and the centrifugal filter on all models is reached after removing the right crankcase cover, and service should be performed at every 6,000 miles or 1 year intervals.

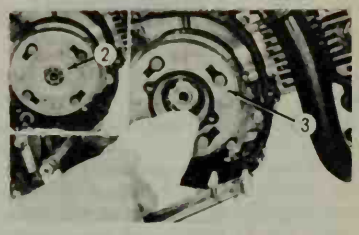
OIL FILTER SCREEN

100/125 cc Models

1. Drain the oil as previously described.

Oil filter screen location (100/125)

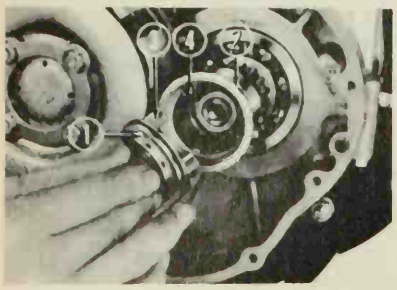
2. Remove the oil filter screen cap. Take out the spring and the filter screen.
3. Wash the screen in solvent; remove any trapped particles; blow dry.
4. Check the screen for punctures or a crushed condition; replace it if necessary. Install the screen, spring, and cap. Tighten firmly.



50–90 cc Models

Service the filter screen at the same time as the centrifugal oil filter. This involves removing the right crankcase cover. See below.

CENTRIFUGAL OIL FILTER



All Models

1. Drain the oil as previously described.
2. Remove the skid plate, if fitted.
3. Remove the kick-starter lever and footpeg(s). Disconnect the tach and clutch cables if these are connected to the cover.
4. Loosen the rear brake adjusting nut so that the brake pedal can be depressed enough to allow the crankcase cover to clear.
5. Place a pan beneath the right crankcase cover. Loosen the cover screws with an impact driver and remove them. Tap the cover gently with a plastic mallet if necessary to free it, and remove the cover.
6. On 100/125 cc models, and the XR75, remove the centrifugal oil filter rotor cover.
7. On 50–90 cc models, remove the clutch housing cover.
8. Clean any metal particles out of the filter with a clean rag. Install the filter cover.

Models which have the clutch on the crankshaft have the centrifugal oil filter located in the clutch center beneath the housing cover (2)

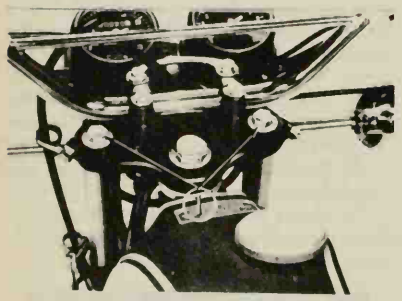
9. On 50–90 cc models, remove the filter screen and clean it in solvent. Check it for punctures and replace it if damaged.

Be sure to line up the tabs (3) on the filter cap with the slots (4) in the rotor (2) (100/125)

10. Before installing the crankcase cover, check the condition of the gasket, and replace it if nicked or damaged.

Front Forks

1. Fork oil should be changed every 6,000 miles or every 12 months.



2. ATF is recommended for all forks, although any quality oil designed for motorcycle forks is acceptable.

Motor oils of varying viscosities (10W-40, 20W, 30W) can also be used.

Various type of oils may not be compatible, however. If you are going to change the *type* of fork oil, it is best to flush the fork legs with a solvent before adding the new type oil. Do not use gasoline, as this may damage rubber parts.

3. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Pump the slider up and down several times until all the old oil is expelled. Then turn the forks all the way to the right to completely drain the right fork leg, or to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit and tighten the drain plug.

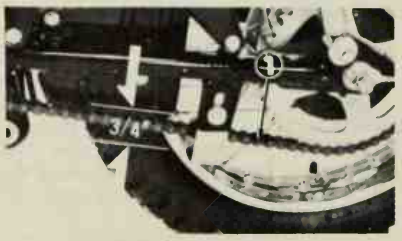
4. Repeat the procedure with the other fork leg.

Fork filler caps

5. Support the front wheel off the ground. Remove the fork filler cap from each fork leg. The handlebar clamps may have to be removed and the handlebars pulled back to allow access to the fork caps. Loosening the upper triple clamp pinch-bolts (if fitted) may make removal easier. On TL125K2 and later models, remove the rubber cap, press down on the plug with a phillips screwdriver, remove the snap-ring and take out the plug.

6. Add the correct quantity of oil to each fork leg. Capacities for each model are given in the "Maintenance Data" chart at the end of this section.

Chassis Lubrication



1. The swing arm pivot on some models is fitted with a grease nipple. This item should be lubricated with a good grade of chassis grease every 3,000 miles. Grease should be applied until some of it shows at either end of the swing arm.

2. Wheel and steering head bearings are lubricated with bearing grease. This should be done every 6,000 miles. Refer to the "Chassis" section for procedures.

SERVICE CHECKS AND ADJUSTMENTS

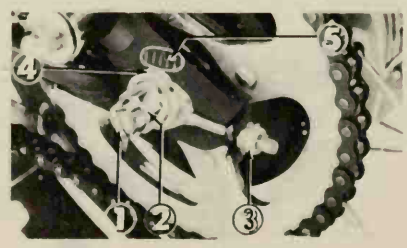
Drive Chain

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.

Chain free-play is measured in the middle of the lower chain run and is the total up-and-down movement of the chain

2. Before checking or adjusting the chain slack, the following conditions should be met:

a. A support should be placed under the engine if necessary, so that the rear wheel is off the ground;



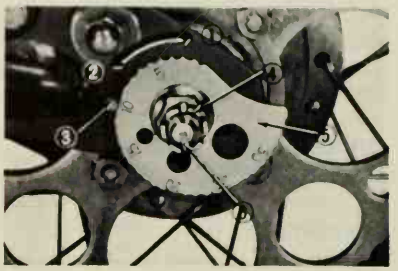
b. The transmission should be placed in Neutral;

c. The chain should be clean and well lubricated;

d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably sprockets which should be replaced as soon as possible.

3. To adjust the chain, first back off the rear brake adjuster nut.

4. Remove the axle nut cotter pin and loosen the axle nut several turns.

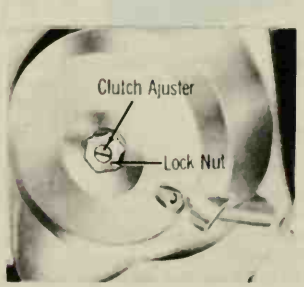


Chain adjustment: (1) cotter pin; (2) axle nut; (3) adjuster nuts; (4) adjuster alignment mark; (5) swing arm alignment marks

5. Turn each of the adjuster nuts by equal amounts until the chain tension is approximately correct.

6. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side.

7. On the TL125, the chain is adjusted by means of eccentric plates. After loosening the axle nut, turn each plate the correct number of serrations until chain tension is correct.



Chain adjuster, TL125: (1 and 2) direction of adjuster plate movement; (3) stud; (4) axle nut; (5) eccentric adjusting plates; (6) cotter pin

If the plates are difficult to move, either pull the wheel back by hand to move the plates off the stud, or tap the side of the tire with your hand while moving the eccentric adjusting plates.

8. Tighten the axle nut and check the chain tension. Then check that the chain has proper tension with the weight of a rider on the machine. Correct if necessary. Tighten the axle nut to the proper torque. Fit a new cotter pin.

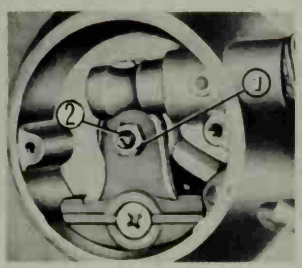
Centrifugal Clutch

1. Models such as the Z50, ST/CT90, CT70, C70M, and several others utilize a centrifugal clutch. No adjustment is necessary if: a) the motorcycle goes smoothly into First gear without a jolt or stalling; b) the motorcycle begins to move as the throttle is opened and moving performance is satisfactory, and c) the clutch does not slip when the kick-starter is operated.

Centrifugal clutch adjuster

2. If adjustment is necessary, loosen the clutch adjusting screw locknut located on the right crankcase cover. Turn the adjusting screw about one turn clockwise (right). Then slowly turn the adjusting screw counterclockwise until resistance is felt. Stop, and turn the screw clockwise about ⅛–¼ turn, and tighten the locknut. Check clutch operation.

Manual Clutch



1. There are two adjusters on the clutch cable. Cable free-play should be maintained at 10–20 mm (0.4–0.8 in.) of hand lever movement measured at the end of the lever.

Use the adjuster at the hand lever for routine adjustments; the one at the engine end can be used for major adjustments.

2. After adjusting the cable to the proper specification, clutch operation should be correct. Gears should be easily engaged (without excessive noise), Neutral should be found easily, and the bike should not have a tendency to creep when in gear with the clutch disengaged. If any of these symptoms are noted, or if clutch slippage is evident, adjust the clutch as follows:

SL70, CT70H, CL70, S65

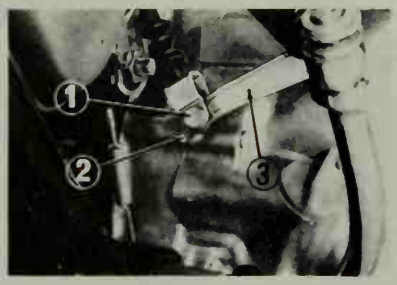
1. Remove the clutch adjuster cover plate on the right crankcase cover. Run down the cable adjuster at the handlebar to give a good deal of cable free-play.

Manual clutch adjusting screw (2) and locknut (1) (70 cc)

2. Loosen the adjusting screw locknut, and turn the screw clockwise until resistance is felt. Then back it off ⅛–¼ turn to the left. Tighten the locknut; adjust the cable free-play as previously outlined. Check clutch operation.

S90, CL90/L, SL90, TL125, 100/125 (76)

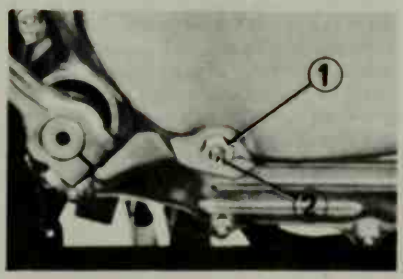
Clutch adjustment is made by adjusting the cable. Use the handlebar or lower end cable adjuster to keep free-play to 10–20 mm (0.4–0.8 in.)



100/125 MODELS, (1975 AND EARLIER), XR75

1. The clutch is adjusted by means of an adjusting screw on the right crankcase cover.

2. If adjustment is necessary, run down the cable adjuster on the handlebar until there is excess play in the cable. Loosen the adjusting screw locknut.



3. On later models, the clutch lever at the engine and the crankcase are fitted with marks. Turn the adjusting screw in or out so that the crankcase mark is aligned with the centerline of the clutch lever, as illustrated. Then tighten the adjusting screw locknut, and set the cable to to the proper free-play.

4. On earlier models, turn the adjusting screw counterclockwise until resistance is felt; stop, and turn the adjusting

On late model 100–125 cc (to 1975), use the adjuster to align the centerline of the clutch lever (1) with the crankcase mark (2)

screw ⅛–¼ turn clockwise, and tighten the locknut. Set the cable free-play to the proper specification.

Clutch adjuster location (100–125 cc) (1975 and earlier)

5. Check clutch operation with the forks turned fully to one side or the other. Be sure that the cable is not kinked or sharply bent anywhere along its route.

Throttle Cable

The throttle cable should be adjusted *after* the idle speed. This procedure is given in the "Tune-Up" section.

The throttle cable should have enough free-play to allow 10–15° of twist-grip rotation before the throttle slide begins to lift.

1. The throttle cable can be adjusted with either the adjuster near the twist-grip, or the adjuster located on the top of the carburetor, beneath the rubber boot. Most have adjusters in both these locations. It is preferable to turn each adjuster out a little way, rather than have one turned out to near its limit.

Front Brake (Drum)

1. Use the adjuster nut at the lower end of the cable or the cable adjuster on the brake plate (depending on model) to allow the handlebar lever to move 20–30 mm (0.8–1.2 in.) before the linings contact the drum. This movement is measured at the tip of the lever.

2. Maintain the adjustment as the linings wear by using the cable adjuster at the handlebar lever.

Front Brake (Disc)

1. The handlebar lever should have 20–30 mm (0.8–1.2 in.) of free-play before the pads contact the disc.

2. The brake cable is self-adjusting; if service is necessary refer to the "Chassis" section.

Rear Brake

1. Use the adjusting nut on the end of the brake rod so that the brake pedal has about 25 mm (1 in.) of travel before the shoes contact the drum.

2. On models which have an auxiliary rear brake lever on the left handlebar, use the brake cable adjuster at the lower end of the cable so that the hand lever will move 20–30 mm (0.8–1.2 in.) before the linings contact the drum.

Note that the two brake adjustments (pedal and lever) are accomplished independently, but adjusting one necessitates adjusting the other.

Brake Wear

1. On disc brakes, the pads are equipped with red wear limit marks; they must be replaced as a set when worn to the red line.

2. Some late models are equipped with brake wear indicator marks on the brake lever and plate. If the marks line up when the brake is fully applied, inspect or replace the brake shoes.

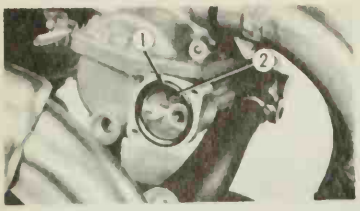
3. When the brake is fully applied, the angle formed by the brake plate lever and the cable or rod should not be greater than 90°. If it is, and brake adjustment is correct, it is probable that the linings are worn to the point of replacement.

Brake Light Switch

The switch should be checked for operation after the brakes are adjusted. The rear brake light switch is adjustable and is mounted in a slotted bracket and secured by locknuts. Moving the switch up on the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Generally, the brake light should come on just as the linings contact the drum.

Steering Stem Bearings

The steering stem bearings should be checked periodically and adjusted if necessary. Refer to the "Chassis" section.

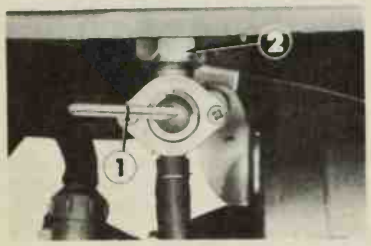


Grasp the fork sliders (with the front wheel supported off the ground) and pull them straight out. No play should be felt. If play is evident or if the bearings bind or make noise when the forks are turned, adjustment and lubrication are needed.

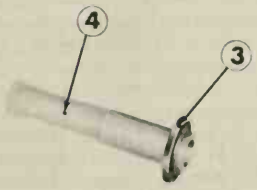
FUEL SYSTEM

1. Fuel system maintenance involves cleaning the petcock and filter, cleaning or replacing the air cleaner, and cleaning the carburetor.

2. The carburetor should be removed, disassembled, and cleaned every 3,000 miles. The procedures are outlined in the "Fuel Systems" section.



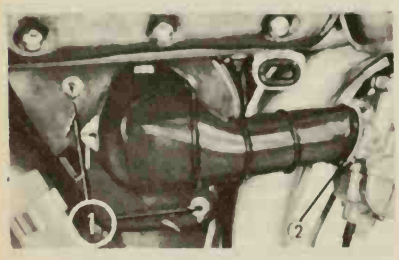
3. The petcock should be serviced every 3,000 miles. On models with a sediment bowl or a carburetor-mounted petcock, shut off the fuel, unscrew the sediment bowl or cover plate and take out the O-ring and filter screen. Clean the parts in solvent and inspect the screen for



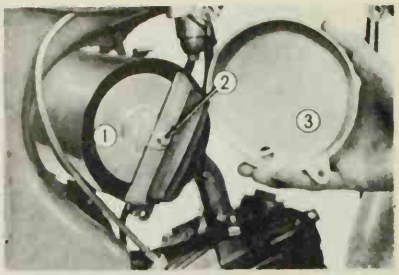
On some models, the O-ring and screen (1 and 2) are located in the carburetor itself

holes or other defects; replace it with a new one if damaged in any way. Inspect the O-ring for any cuts or cracks and replace it if necessary. After installing the parts, turn on the fuel and check for leaks.

Some models require that the petcock be removed to clean the filter screen. In this case, drain the gas tank, disconnect the fuel lines, and unscrew and remove the petcock. Clean the filter. Check the condition of the rubber petcock washer. After installation, check for leaks.



Petcock (1), securing nut (2), the O-ring and filter screen (3 and 4) are located on the petcock intake pipe

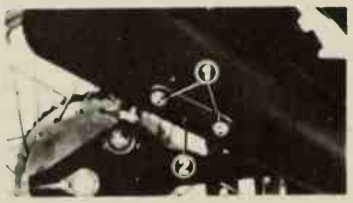


Air Cleaner Service

1. Newer models are equipped with a foam-type filter element. After removing the element, wash it in solvent (such as kerosene) and wring dry. Then soak the element in SAE 10W–30 oil and wring off the excess. Reinstall.

Filter maintenance should be carried out at least every 1,500 miles, or 30 operating days, but more often if the machine is operated in dusty areas.

Air cleaner securing nuts (1), and spring clamp (2) (100-125 cc)



Air cleaner element (1), securing bolt (2), and cover plate (3) (90 cc)

2. Older models have a paper element. The filter element is serviced by brushing off the outside with a stiff brush to loosen any accumulated dirt. Then apply compressed air through the inside of the filter to remove the deposits.

Note that this method is only partially effective. It is recommended that the element be replaced after two or three such cleaning operations. Replacing the paper element with the newer foam-type if possible is recommended.

DECARBONIZATION

1. Models equipped with spark arrestors should have this item serviced every 1,500 miles or every 30 operating days. Excessive carbon buildup in the spark arrestor will cause sluggish performance and possible engine overheating.

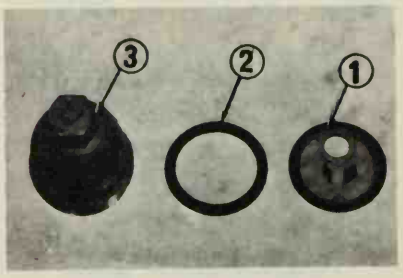
Spark arrestor cover plate (2) and securing screws (1) (XR75 shown)

2. Models may be equipped with a simple spark arrestor cover plate, or a removable baffle at the end of the muffler, or both, depending on the type of exhaust system fitted (see the illustrations).

3. Spark arrestor maintenance should be done when the engine is cold.

Spark arrestor (2) and securing bolt (1) (ST90 shown)

4. On models with only a spark arrestor cover plate, remove the cover screws and the cover. Start the engine, allow it to warm up, and rev it about 20 times to clean out the arrestor port. Check the condition of the cover plate gasket, and fit a new one if damaged.

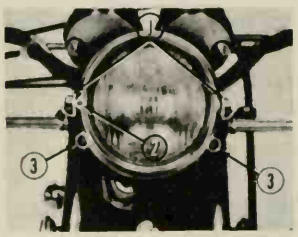


5. On models with a removable baffle, remove the securing bolt at the end of the exhaust pipe. Grasp the spark arrestor with large pliers and pull it out.

Heat the spark arrestor with a propane torch until it is quite hot. Grasping the arrestor with large pliers, tap it against a wooden block to knock off carbon particles. When it cools, remove the rest of the deposits with a stiff wire brush and solvent.

Before replacing the arrestor, start the engine and rev it several times to remove any carbon built up in the muffler.

6. On models with both a cover plate and a removable arrestor, perform both Steps (4 and 5).



NOTE: *These procedures must be carried out out-doors in an area away from combustible materials.*

Petcock components: (1) filter screen; (2) O-ring; (3) sediment bowl

HEADLIGHT ADJUSTMENT

Set the machine about 25 feet away from and perpendicular to a wall, preferably of a color which reflects light well.

Headlight mounting bolts (1), lateral adjusting screw (2), and rim mounting screws (3)

The machine should be off the stand, and with a rider putting his weight on the machine as in operation. Start the engine and switch on the high beam. The headlight high beam should be parallel to the ground, and should hit the wall directly in front of the machine.

Vertical adjustment is made by loosening the two headlight mounting bolts slightly and pivoting the headlight up or down.

Lateral adjustment is made by means of the screw on the right-side of the headlight. Turning the screw clockwise will move the beam to the left and vice versa.

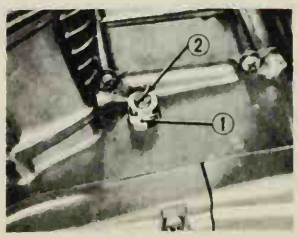
TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in "General Information."*



CAM CHAIN ADJUSTMENT

NOTE: *Early models under 100 cc had an automatically tensioned cam chain. No adjustment is necessary. For other models, refer to the appropriate heading below.*

100/125 cc Engines

1975 AND EARLIER

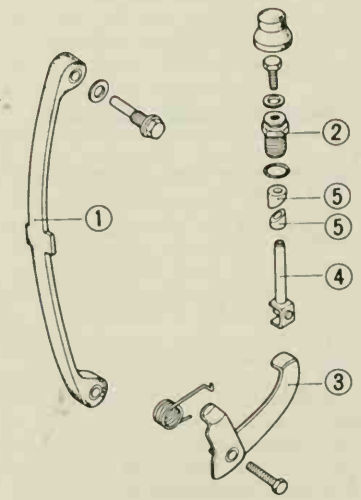
1. The cam chain adjuster and locknut are located on the top of the crankcase behind and to the left of the cylinder, beneath a rubber cap.
2. With the engine idling, note the indication of chain noise. Chattering will indicate that the chain is too loose; whining means that it is too tight.
3. With the engine idling, loosen the adjuster locknut. Turn the adjuster clockwise about half a turn so that it is loose; then turn it counterclockwise to take up slack in a loose chain.
4. Turn the adjuster until resistance is felt. The chain should be operating quietly at this point. It should not be necessary to turn the adjuster very much to achieve adjustment.
5. Tighten the adjuster locknut.
6. If the adjuster was turned too far, the chain will be too tight and will begin to whine. In this case, repeat the adjustment procedure until quiet operation is obtained.

Cam chain adjuster (2) and locknut (1) (100–125, to 1975)

1976 MODELS

1. The cam chain adjuster is located behind and to the left of the cylinder, beneath a rubber cap.
2. With the engine idling, loosen the large adjusting bolt, then retighten. Tension will be set automatically.

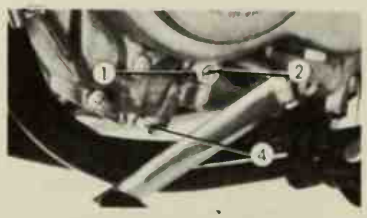
NOTE: *A 6 x 10 mm bolt is fitted to the top of the adjusting bolt. Do not loosen this bolt.*



50–90 cc Engines (Except XR75)

Some early models such as the Z50-K2 have an automatic tensioner; no adjustment is necessary. For other models, proceed as follows:

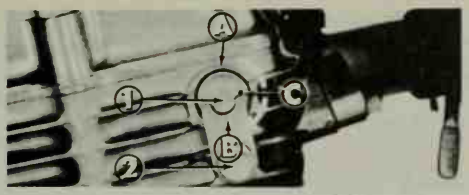
1. Cam chain adjustment is made with the engine idling. The adjustments can be made in two ways: either with the adjusting screw or with the tensioner bolt.



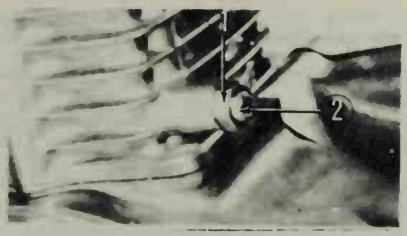
The adjusting screw locks the spring-loaded tensioner rod in place, and loosening it will allow tension to be automatically taken up.

The tensioner bolt allows the tensioner rod to be moved, compressing the tensioner itself.

Cam chain adjuster (100–125, 76)



1. Cam chain tensioner
2. Adjusting bolt
3. Tensioner arm
4. Set bar
5. Collars



Locknut (1), adjusting screw (2), and tensioner cover bolt (4) (50-70 cc)

The adjusting screw is located at the bottom of the left crankcase cover. The tensioner bolt is just below the adjusting screw, beneath a cover bolt.

2. With the engine idling, loosen the adjusting screw locknut and back the screw off (counterclockwise) about ½ turn. Tighten the adjusting screw. If chain operation is now quiet, tighten the adjusting screw locknut, since the adjustment is now complete. If chain operation is still noisy, proceed as follows:
3. Remove the tensioner cover bolt. Loosen the adjusting screw locknut and back off the adjusting screw about ½ turn.
4. Turn the tensioner bolt in or out slowly until proper chain operation is obtained. If the chain chatters, it is too loose and the tensioner bolt should be turned clockwise; if the chain whines, it is too

Cam chain adjuster plate bolt (2), chain adjuster (1); median position (C) (XR75)

Cam chain tensioner (2) and locknut (1) (XR75)

tight, and the tensioner bolt should be turned counterclockwise.

5. When chain operation is quiet, replace the cover bolt, tighten the adjusting screw and the adjusting screw locknut. Adjustment is now complete.

XR75

1. Adjust the cam chain if operation is noisy. The adjuster is located at the top left-side of the cylinder head.

2. Adjust the cam chain with the engine idling. Loosen the chain adjuster plate bolt. If the chain chatters, turn the adjuster clockwise to take up excess slack. If the chain whines, turn the adjuster counterclockwise to increase slack.

NOTE: *Do not attempt to turn the adjuster more than 90° from the median position.*

3. When chain operation is quiet, tighten the plate bolt.

4. If turning the adjuster fully to position "B" in the illustration fails to quiet a loose chain, proceed as follows:

5. Shut off the engine. Remove the magneto cover, spark plug, and head cover. Turn the engine over (counterclockwise) until the intake valve goes down and comes up. Continue turning the engine over until the "T" mark on the rotor is aligned with the index mark on the crankcase cover. The piston is now at top dead center on the compression stroke.

6. The cam chain tensioner is located at the bottom rear of the cylinder.

Loosen the adjuster plate bolt, and turn the adjuster so that the punch mark lines up with position "C" as shown in the illustration. This is the middle of the adjustment range.

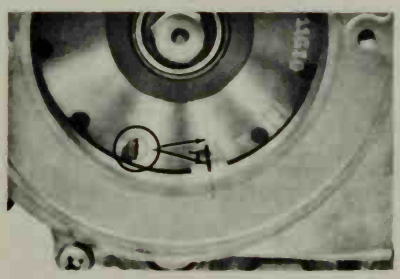
7. Holding the piston at TDC, loosen the tensioner locknut. Back the tensioner off about ½ turn, then tighten it. Secure the locknut.

8. Start the engine and make any adjustment to the cam chain necessary using the adjuster on the head as before.

VALVE ADJUSTMENT

All Models

NOTE: *Valves must be adjusted when the engine is cold.*

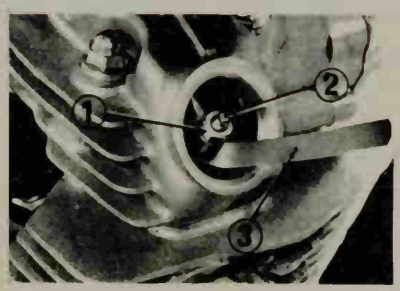


1. Remove the alternator or magneto rotor cover or inspection cap.

2. 100/125 and XR75: Remove the gas tank.

3. Remove the intake and exhaust valve caps, or the head cover on the XR75.

4. Remove the spark plug.



5. Turn the engine over slowly in the normal direction of rotation (the rotor will turn counterclockwise) while observing the intake valve. When the valve goes down and begins to come up, continue turning the engine over until the "T" mark on the rotor lines up with the timing index mark on the crankcase cover.

Piston top dead center occurs when the "T" mark on the rotor aligns with the index mark on the crankcase cover (1) (100-125 cc shown)

6. The piston should now be at top dead center on the compression stroke with both valves closed. Check for clearance at the valves. Each should have a slight amount of free-play. If they do not, the piston is at TDC on the exhaust stroke. Turn the rotor 360° and check again.

7. Valve clearance for all models is 0.002 in. (0.05 mm) for both intake and exhaust valves.

Adjusting the valve clearance: loosen the adjuster locknut (1) and turn the adjuster (2) until the feeler gauge (3) is a slip fit between the adjuster and the valve

8. If adjustment is necessary, loosen the adjuster locknut and turn the adjuster to effect proper adjustment. Tighten the locknut.

NOTE: *The adjustment may change when the locknut is tightened. Hold the adjuster steady while securing the nut. Recheck the clearance afterward.*

9. Repeat the procedure at the other valve.

CONTACT BREAKER POINTS

Location

1. On battery ignition 90, 100, and 125 cc machines and the magneto-ignition TL125, the points are located in a case on the left-side of the cylinder head, and are operated off the camshaft. The timing advance mechanism is fitted behind the breaker point plate.

2. On 50–70 cc machines, the points are fitted to the stator plate beneath the magneto rotor. The timing advance mechanism is fitted to the rotor, on those models which have one.

Replacement

1. If replacement of the points is necessary, this is easily accomplished on all 90–125 cc bikes by disconnecting the primary wire, removing the two point securing screws and taking off the points. Install the new points after thoroughly cleaning off the contact surfaces with a non-oily solvent, and adjust the gap.

2. On 50–70 cc machines, remove the left crankcase cover. Use the special puller to remove the magneto rotor after removing the rotor nut. Disconnect the primary wire, remove the points securing screw. Install the new point set and reset the gap. Check the ignition timing.

CAUTION: *Ensure that all insulating washers are correctly installed. Check that there is no continuity between the primary wire and the engine when the points are open, and that there is continuity when they are closed.*

3. Apply a bit of grease to the breaker cam lubricating wick. Take care not to apply too much to avoid fouling the points.

Gapping

Gapping is necessary to compensate for wear of the contact surfaces due to electrical arcing and for wear of the breaker point fiber heel. As the heel wears the points will open later relative to the rotation of the crankshaft, retarding the timing.

Points should be filed (if necessary) and cleaned before gapping.

NOTE: *On 50–70 cc machines the ignition timing is adjusted by changing the point gap. Therefore these operations must be carried out at the same time.*

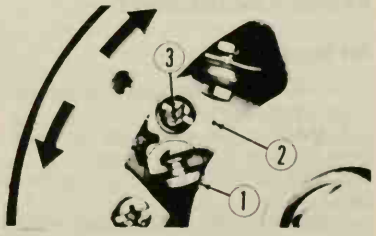
90–125 CC

1. Remove the points cover.
2. Turn the engine over slowly until the points are open to their maximum gap.
3. With the proper feeler gauge, check the gap. The proper specification for all models is 0.012–0.016 in. (0.3–0.4 mm).

To adjust the point gap, loosen the two screws (1), and lever the points with a screwdriver at (2) (90-125 cc)

4. If adjustment is necessary, loosen the two screws which secure the points to the base plate, and use a thin screwdriver at the pry slot provided to bring the gap to the proper specification.



NOTE: *Loosen the screws just enough to allow the points to be moved. If too loose, the points will snap shut instead of holding the adjustment.*

5. Tighten the screws and recheck the gap. It may change slightly when the screws are tightened.
6. If it is not possible to gap the points correctly, the fiber heel is evidently worn, and the point set should be replaced.

50–70CC

1. On these models, adjusting the point gap is the only method of adjusting the ignition timing, so the timing should be checked whenever the points are gapped.
2. Remove the rotor cover.
3. Turn the engine over, observing the points through the cutout in the rotor until they are opened to their maximum gap.
4. With the proper feeler gauge blade, check the gap. Proper gap for all models is 0.012–0.016 in. (0.3–0.4 mm).
5. If adjustment is necessary, loosen the point securing screw, and use a thin screwdriver at the pry slot provided to bring the gap to within the proper specification.

NOTE: *Loosen the securing screw just enough to allow the gap to be adjusted.*

The point securing screw (3) is loosened slightly to change the point gap on most 50-70 cc models

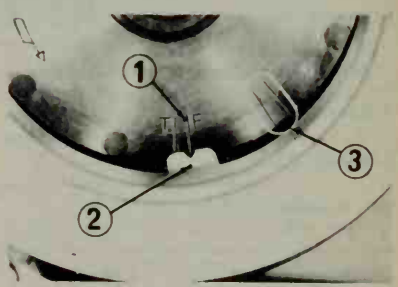
IGNITION TIMING

Dynamic Timing

ALL MODELS

1. Remove the magneto or alternator rotor cover so that the timing marks are visible.



2. Hook up the timing light according to the manufacturer's instructions. Most lights use the vehicle's own battery as a power source.

3. Start the engine, aiming the light on the rotor. Note the following:

a. At idle, the "F" mark on the rotor should line up with the timing indicator on the crankcase cover;

b. As the revolutions increase, the "F" mark should be seen to move in a direction opposite that of crankshaft rotation (except on Z50 and CT70 models which do not have timing advance mechanisms);

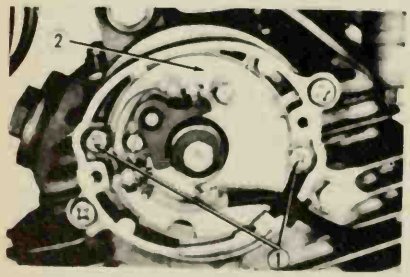
c. Finally, at full advance (about 3,000 rpm and above on most models), the twin rotor marks must line up with the timing indicator mark on the crankcase cover.

The "F" mark (1) is the firing point with the timing not advanced. The two slash marks (3) indicate the full advance firing point. (2) is the stationary timing mark

4. The full advance reading is the most important. If the rotor and crankcase marks do not align, proceed as follows:

5. 90–125 cc models: remove the points cover. Loosen the two screws which secure the breaker base plate just enough to allow the plate to be turned. Using a thin screwdriver applied at the pry point provided, rotate the plate in the direction necessary so that the timing marks align.

Rotating the plate clockwise advances the timing; rotating it counterclockwise retards the timing.



Tighten the breaker plate screws and recheck the timing.

6. 50–70 cc models: Timing is adjusted by changing the point gap. Set the point

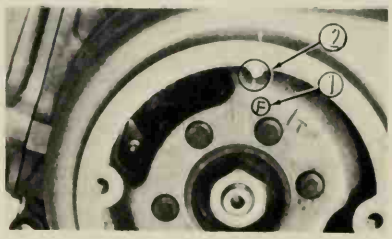
To adjust the ignition timing, loosen the two screws (1), and rotate the base plate (2) (90-125 cc)

gap to the proper value (0.012–0.016 in./0.3–0.4 mm) as previously outlined. If the strobe light indicates that the timing is not incorrect, increase or decrease the point gap until it is.

NOTE: *Increasing the point gap advances the timing; decreasing it retards the timing. The point gap must still remain within the limits given. If it is not possible to correct the timing while retaining the proper gap, the points must be replaced.*

Static Timing



90–125 CC MODELS

1. Remove the alternator rotor cover and the points cover. Remove the spark plug and intake valve cover.
2. Hook the tester up. Remember that if a light is used on the magneto ignition TL125, the black/white points wire must be disconnected.
3. Turn the engine over so that the engine is just beginning its compression stroke. (The intake valve will go down and come up). Turn the rotor slowly in the normal direction of rotation (counterclockwise). At the instant in which the "F" mark on the rotor aligns with the mark on the crankcase cover, the points should begin to open as indicated by the reaction of the test light or the meter.
4. If the points open before the marks align, the timing is too advanced. If they open after the "F" mark passes the stationary mark, the timing is too retarded.
5. If the timing is not correct, loosen the two phillips screws which secure the breaker base plate to the engine. Loosen them just enough to allow the plate to be rotated.
6. Turn the plate using a thin screwdriver applied to the pry slot provided so that the points open just as the "F" mark lines up with the stationary mark. If the timing was too advanced, turn the plate counterclockwise. If too retarded, rotate the plate clockwise.
7. Tighten the breaker plate screws and recheck the timing. Sometimes this will cause the plate to move slightly and throw the timing off.

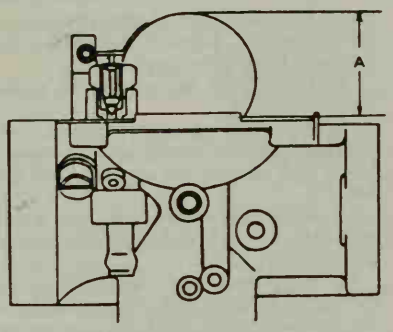
50–70CC MODELS

The timing on these models is accomplished by changing the point gap.

1. Remove the spark plug and the magneto rotor cover.
2. Clean and gap the points to the proper specification as outlined under "Gapping."
3. Hook up the ohmmeter to ground and to the black wire coming from the points.

The points should just begin to open when the "F" mark on the rotor aligns with the stationary timing mark (50-70 cc)

4. Turn the rotor slowly in the normal direction of rotation (counterclockwise). When the "F" mark on the rotor and the stationary timing mark on the crankcase align, the meter should indicate that the points have just begun to open.
5. If the points open after the "F" mark passes the stationary mark, the timing is too retarded; if they open before the "F" mark aligns, the timing is too advanced.
6. As noted above, ignition timing is corrected by changing the point gap. If the timing was retarded, increase the point gap. If it was advanced, decrease the point gap.



NOTE: *It should be possible to set the timing perfectly while maintaining the point gap within the specification given (0.012–0.016 in. 0.3–0.4 mm). If the timing marks will not align when the point gap is within this specification, the points must be replaced. Wear of the fiber heel is one cause of this condition.*

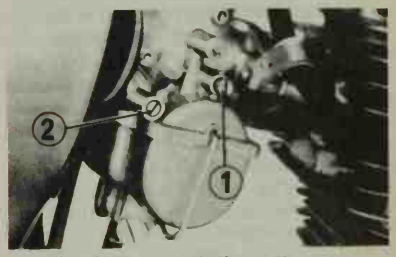
CARBURETOR

Adjusting Float Level

Generally, float level will not need adjustment unless the carburetor has been disassembled, fuel delivery problems have been noted, or considerable mileage has been covered.

1. Remove the carburetor from the motorcycle as outlined in the "Fuel Systems" section.
2. Remove the float bowl. Remove the float bowl gasket.
3. Float level is defined as the measured distance from the float bowl mating surface on the carburetor body (gasket removed) to the top of the floats, when the tang of the float arm is just touching the end of the float needle. A special gauge is available to check the float level although a vernier caliper can also be used.
4. With the carburetor upside down, gradually lower the floats until the tang of the float arm just touches the end of the float needle. The tang should not depress the needle, but just contact it. Measure

Float level is the distance "A" from the float bowl gasket surface (gasket removed) to the top of the floats



the distance from the carburetor body to the top of the floats. Compare the reading with the proper float level for your machine as given in the "Tune-Up Specifications" chart at the end of this section.

5. If adjustment is necessary, bend the float arm tang *only* to raise or lower the float level.
6. Float level will not be correct if the needle is worn, or if there is foreign matter on the needle seat. Refer to "Carburetor" for more information.

Idle Speed and Mixture

NOTE: *These items must be adjusted when the engine is at operating temperature.*

1. Ensure that the throttle cable adjustment is approximately correct so that the cable has enough slack to allow the throttle slide to be fully closed.
2. Screw the pilot air screw in (carefully) until it bottoms lightly, then turn it out the number of turns shown in the "Tune-Up Specifications" chart at the end of this section.
3. Start the engine. When operating temperature is reached, adjust the throttle stop screw so that the engine idles as slowly as possible. Then turn the pilot air screw in or out until the engine runs smoothly. It should not be necessary to vary the air screw more than one half turn in either direction from the given setting.

Throttle stop (1) and pilot air (2) screws

4. Adjust the throttle stop screw so that the engine idles at the desired rpm.

NOTE: *If proper idling cannot be obtained using this method, it may be that the fuel system is clogged with dirt (check petcock, filter, carburetor), the plug is bad or too cold, the valves are improperly adjusted, or there is an air leak somewhere in the system.*

5. After adjusting the idle speed and mixture, adjust the throttle cable as outlined in the "Maintenance" section.

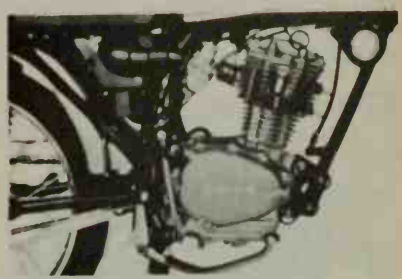
ENGINE AND TRANSMISSION

Removal and installation procedures are given below. Specifications are in the charts at the end of this section. For service procedures of common engine components such as cylinder head, pistons, clutch, etc., refer to the "Engine Rebuilding" section in "General Information."

ENGINE REMOVAL AND INSTALLATION

The following notes apply to all models:

1. Drain the oil before removing the engine.
2. Degreasing and thoroughly cleaning the engine before removal is highly recommended. Be especially attentive to the cylinder base and the underside of the crankcase, and around mating surfaces.
3. On models which have the fuel petcock incorporated into the carburetor, use a C-clamp to pinch off the fuel line before removing the carburetor from the cylinder head.
4. When disconnecting the final drive chain, use pliers to remove the masterlink spring clip. Do not pry the clip off with a screwdriver or it will be distorted and then must be replaced.



After disconnecting the chain, install the masterlink on one end of the chain to prevent loss.

NOTE: *On models with a full coverage chaincase, wire the ends of the chain together and attach them to a point on the frame so that the chain doesn't fall into the chaincase.*

5. Upon installation, install the spring clip with the closed end facing the direction of chain rotation.

100/125 cc Models

1. Remove the exhaust pipe and muffler. Remove the seat and the gas tank.
2. Remove the rider footpegs (except TL125) by removing the step bar bolted to the lower frame members.
3. Run down the clutch cable adjuster(s) and disconnect the cable from the lever on the engine.
4. Unbolt the carburetor from the engine, and hang it well out of the way to avoid possible damage.
5. Remove the left and right frame sidecovers. Disconnect the alternator leads at the plastic connector. Remove the spark plug cap. Loosen the spark plug. Disconnect the ignition primary wire at the connector near the ignition coil.
6. Disconnect the tach cable at the engine (if fitted).
7. Remove the gearshift lever pinchbolt and carefully pull the shift lever off the splined shaft. Back off the rear brake adjuster.
8. Remove the left rear crankcase cover. Disconnect the chain.
9. Back off the rear brake adjuster nut to allow a good bit of movement in the brake pedal.
10. Remove the front engine mounting nuts and bolts and remove the mounting plates. Remove the top and rear mounting bolts; remove the engine from the frame.

Engine mounting bolt locations

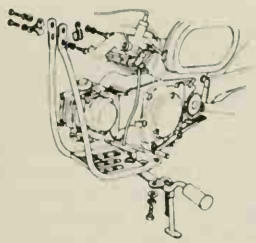
11. Installation is the reverse of the removal procedure. After the engine is fitted into the frame, use a screwdriver

through the top mounting bracket to support the engine until the other mounting bolts are fitted.

12. Exhaust system nuts and bolts must be tightened gradually.

ST90

1. Remove the right shock absorber, and remove the muffler along with the rear brackets.



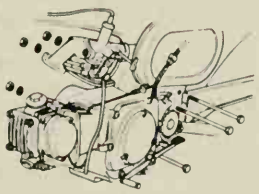
2. Disconnect the spark plug lead and loosen the plug.

3. Unbolt the carburetor from the cylinder head.

4. Remove the rear portion of the left crankcase cover, and disconnect the drive chain.

5. Disconnect the electrical wiring at the plastic connectors. Disengage the carburetor drain tube from the engine clamp.

6. Have an assistant support the motorcycle. The front downtubes (subframe) must be removed and the sidestand along with it.



Sub-frame and footpeg assembly (ST90)

7. Remove the footpeg step bar.

8. Remove the sub-frame.

9. Remove the nuts on the rear engine mounting bolts. Support the engine so that it will not fall, and pull out the rear mounting bolts.

Engine mounting bolts (ST90)

10. Remove the engine from the frame.

11. Before installing the engine, bolt the step bar to it. The remainder of installation is the reverse of removal.

CT90, C90

1. Remove the front fender (CT90) (early models).

2. Remove the frame tube cover (CT90). Remove the fairing (C90).

3. Remove the footpeg step bar.

4. Remove the rear portion of the left crankcase cover and disconnect the drive chain (C90). On the CT90, disconnect the chain and disengage it from the countershaft sprocket.

5. Remove the muffler.

6. Unbolt the carburetor manifold from the cylinder head.

7. Disconnect the electrical wiring at the connectors. Remove the spark plug lead and loosen the spark plug.

8. Disconnect the rear brake pedal return spring.

9. Remove the front downtubes, then remove the top and rear engine mounting bolts, and remove the engine from the frame.

10. Raise the engine into the frame and have an assistant route the wiring into position.

12. Insert the lower rear mounting bolt through the frame lug and engine from the left-side, then pivot the engine up and install the remaining bolts.

13. The remainder of installation is the reverse of the removal procedure.

SL90

1. Remove the exhaust system.

2. Remove the rear portion of the left crankcase cover, and disconnect the drive chain.

3. Run down the clutch cable adjusters, and disconnect the cable from the engine lever.

4. Remove the spark plug lead and loosen the spark plug.

5. Disconnect the carburetor manifold from the cylinder head.

6. Remove the gearshift and kickstarter lever pinch-bolts, and carefully pull these levers off their shafts.

7. Remove the left sidecover and disconnect the electrical wires at the connectors.

8. Remove the four bolts for the top rear engine mounting plates.

9. Remove the bottom engine mounting bolts and remove the engine from the frame.

10. Installation is the reverse of the removal procedure.

S90, CL90/L, CD90

1. Remove the rider footpeg step bar.

2. Remove the exhaust system.

3. Remove the rear portion of the left crankcase cover and disconnect the drive chain.

4. Run down the cable adjusters and disconnect the clutch cable from the lever at the engine.

5. Disconnect the spark plug lead and loosen the spark plug.

6. Unbolt the carburetor manifold from the cylinder head.

7. Remove the battery cover and disconnect the battery leads. Disconnect the alternator leads at the connector.

8. Unhook the brake pedal spring.

9. Remove the top and rear engine mounting bolts and remove the engine from the frame.

10. Installation is basically the reverse of the removal procedure. Note the following points:

a. Block up the engine under the frame;

b. Route the wiring harness up to the battery box and suspend the engine from the frame by inserting a screwdriver into a frame and engine mounting point;

c. Insert the engine mounting bolts from the left-side, then secure and torque the mounting nuts;

d. Connect the brake pedal return spring to the lower mounting bolt;

e. Connect all the wiring harness leads;

f. Connect the battery leads to the battery terminals, push the wires up into the top of the battery box, install the battery, taking care not to pinch any of the wires, and route the battery overflow tube down through the bottom of the battery box;

g. Connect the clutch cable to the release lever;

h. Install the intake manifold to the cylinder head, taking care to correctly position the O-ring between the manifold and the cylinder head;

i. Attach the high-tension lead to the spark plug. The lead should be secured by the clip under the right-side intake manifold mounting bolt;

j. Install the muffler assembly.

XR75

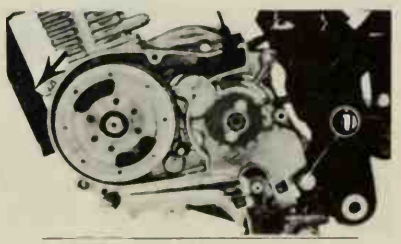
1. Remove the muffler.

2. Unbolt the carburetor manifold from the cylinder head.

3. Loosen the adjusters on the clutch cable and disconnect the cable from the lever on the engine.

4. Remove the spark plug cap and loosen the spark plug.

5. Remove the left-side crankcase cover. Disconnect the drive chain.



6. Disconnect the magneto wire at the connector.

7. Loosen all of the mounting bolt nuts.

8. Remove the front mounting bolts and mounting plates. While supporting the engine with one hand, remove the upper rear mounting bolt.

9. Let the engine swing forward; then remove the lower rear bolt.

10. Installation is the reverse of removal.

Lower rear engine mounting bolt (XR75)

SL70

1. Remove the seat by loosening the shock absorber capnuts and pulling it off. Disconnect the fuel line at the petcock and fold back the rubber mounting at the rear of the gas tank. Pull the gas tank back and off the machine.

2. Remove the frame sidecovers. Disconnect and remove the battery. Remove the tool box. Remove the chain guard. Remove the gearshift lever and the kickstarter lever.

3. Remove the engine left-side cover. Use an impact driver to loosen the phillips screws to avoid damage.

4. Disconnect the drive chain.

5. Remove the exhaust system after

unbolting the muffler from the frame and the exhaust pipe from the cylinder head.

6. Loosen the carburetor air cleaner hose clamp screw, remove the air cleaner case mounting bolts, and remove the case.

7. Unscrew the carburetor cap and pull out the slide assembly. Tape the slide out of the way to avoid damage. Remove the manifold bolts at the cylinder and take away the manifold and carburetor as a unit. Plug the cylinder intake port with a clean piece of rag to keep foreign matter out.

8. Disconnect the electrical wiring at the plastic coupler. Remove the spark plug cap. Loosen the plug.

9. Disconnect the clutch cable at the engine.

10. Remove the two engine mounting plate bolts on the right engine mounting plate. Remove the long engine mounting bolts (two). The lower bolt is removed by loosening it from the left-side. Remove the right-side engine mounting plate.

11. Protect the frame tubes with a covering of some sort. Remove the engine by moving it forward in the frame, then swing the back of the engine out to the right and take the engine out of the frame.

12. Installation is the reverse of the above. Tighten engine mounting bolts to 15–22 ft lbs.

13. When installing the muffler, check the gasket for damage and replace it if necessary. Tighten the muffler bolt and the cylinder mounting nuts gradually.

CL70

1. Remove the gearshift lever pinch-bolt, and carefully pull the lever off the splined shaft.

2. Remove the footpeg step bar.

3. Remove the rear portion of the left crankcase cover and disconnect the drive chain.

4. Remove the exhaust system.

5. Unbolt the carburetor intake manifold from the cylinder head.

6. Run down the clutch cable adjusters and disconnect the cable from the engine lever.

7. Disconnect the spark plug lead and loosen the plug.

8. Remove the battery cover and disconnect the wiring at the connector.

9. Disconnect the rear brake pedal return spring from the pedal.

10. Remove the engine mounting bolts and nuts and remove the engine from the frame.

11. Installation is the reverse of removal.

CT70/H

1. Remove the engine bash plate (two bolts).

2. Remove the exhaust system which is secured at the cylinder head and two places on the frame.

3. Remove the spark plug.

4. Unscrew the carburetor cap, pull out the slide assembly, and arrange it so that it is out of the way and won't be damaged when the engine is removed.

5. Remove the four bolts which secure the crankcase protector downtubes to the frame near the steering head.

6. Remove the chain guard. Remove the left crankcase cover. Disconnect the drive chain.

7. Remove the two bolts beneath the engine which secure the skid plate portion of the crankcase protector, and remove it.

8. Remove the step bar (two bolts).

9. Disconnect the rear brake pedal return spring at its top mount.

10. Remove the carburetor intake manifold from the cylinder head.

11. Remove the two engine mounting bolts, and remove the engine.

12. Installation is the reverse of removal.

C65/M, C70/M, S65

1. Remove the air cleaner assembly (except S65).

2. Remove the fairing (if applicable).

3. Remove the exhaust system.

4. Remove the footpeg step bar.

5. Remove the tool box.

6. Unbolt the carburetor (C models) or the manifold (S65) from the cylinder head.

7. Run down the clutch cable adjuster and disconnect the cable from the engine lever.

8. Remove the pinch-bolts and take off the gearshift and kick-starter levers.

9. Remove the left-side crankcase cover. Disconnect the drive chain.

10. Remove the spark plug. Detach the spark plug lead from the clip on the right sidecover. Disconnect the starter motor lead and the electrical wiring.

11. Disconnect the rear brake pedal return spring and stoplight switch spring.

12. Support the engine while removing the rear mounting bolts; remove the engine from the frame.

13. Installation is the reverse of removal.

Z50

1. Remove the exhaust system.

2. Unscrew the carburetor cap, and pull out the throttle slide assembly. Secure it out of the way to avoid damage.

3. Remove the lead and loosen the spark plug.

4. Disconnect the magneto wiring at the plastic connector.

5. Disconnect the fuel line from the carburetor.

6. Remove the left crankcase cover. Disconnect the drive chain.

7. Remove the two engine mounting bolts while supporting the engine; remove the engine from the frame.

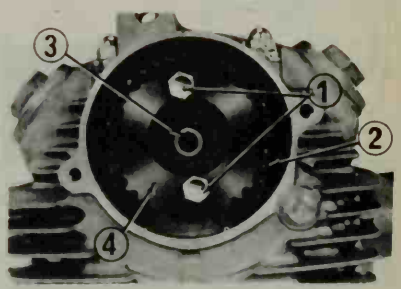
8. Installation is the reverse of removal.

TOP END

The following section deals with the removal and installation of the cylinder head, cylinder, piston, and related components. Inspection and service procedures for these and other common engine components are outlined in the "Engine Rebuilding" section in "General Information." Specifications for individual models are given in the charts at the end of this section.

100/125 cc Models (1975 and Earlier)

REMOVAL



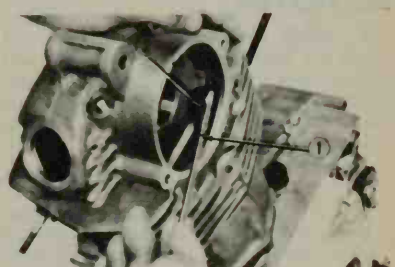
1. Removal of the top end necessitates removing the engine from the frame. Refer to the "Engine Removal and Installation" procedures.

2. Remove the breaker point cover. Scribe a line across the breaker plate to the engine to preserve ignition timing. Remove the two breaker plate screws and remove the plate. Remove the valve adjusting hole caps and loosen the adjusters.

3. Remove the bolt which secures the breaker cam. Pull the breaker cam and spark advance assembly off the camshaft.

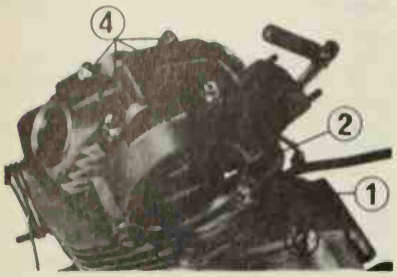
4. Remove the two screws which hold the breaker point housing to the engine. Use an impact driver to loosen these screws. Remove the housing.

5. Loosen the cam chain adjuster screw locknut (on the crankcase) and unscrew the tensioner screw a few turns. Place a clean rag beneath the cam sprocket, and carefully remove the sprocket bolts. Remove the sprocket.



Sprocket bolts (1), cam chain (2), camshaft (3), and sprocket (4)

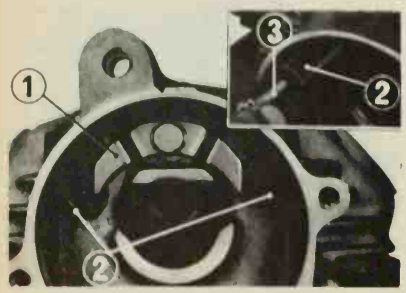
Loop a piece of wire around the cam chain and secure it to any fixed point to prevent the chain from falling into the crankcase.



6. Pull out the camshaft. Note that the camshaft will have to be turned to allow the intake and exhaust lobes to clear the opening through which the cam is removed. Perform this operation carefully. Hold the chain out of the way as the cam is removed.

7. Remove the cam chain tensioner mounting bolt in the head and detach the tensioner from its seat in the head.

Prying the tensioner (2) out of its seat with a screwdriver (1)



8. Remove the cylinder head bolt beneath the breaker point housing. Remove the four capnuts on top of the cylinder head. Remove the cylinder head.

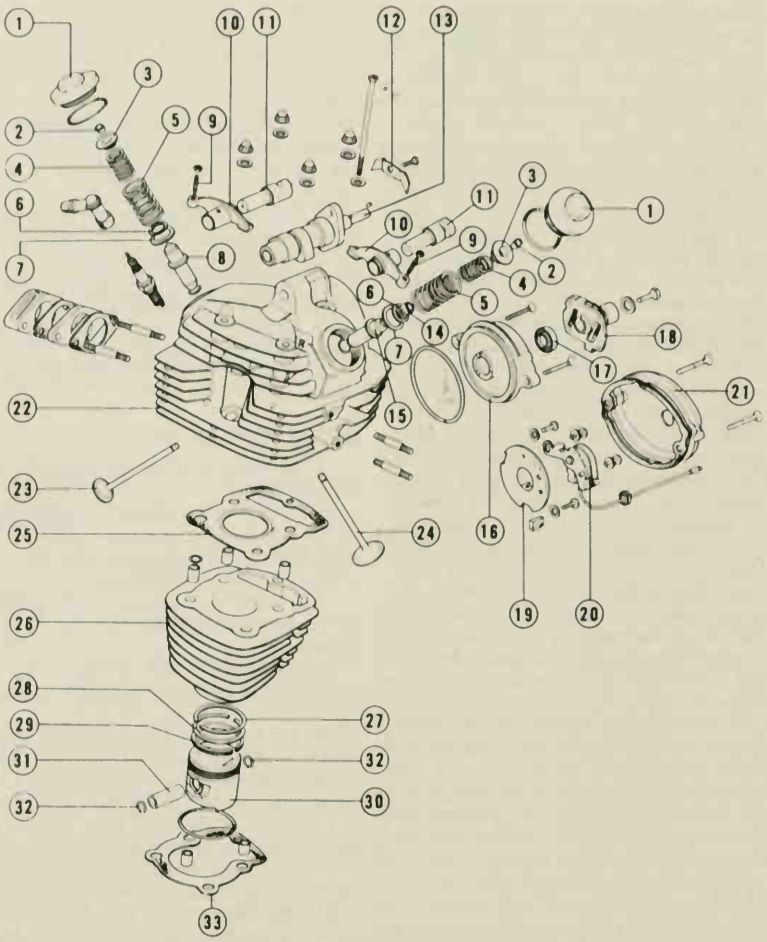
Cam chain tensioner mounting bolt (1), tensioner (2), cylinder head (3), and cylinder head capnuts (4)

9. Remove the cam chain guide from the cylinder. Lift the cylinder up on its studs until there is enough room to stuff a clean rag between the cylinder and the crankcase. This will catch any foreign matter or pieces of broken ring which might fall into the cases when the cylinder is removed.

10. After removing the cylinder, remove the piston wrist pin circlips with needlenose pliers. Push out the wrist pin with a suitable drift.

Remove the bolt which secures the rocker arm shaft retaining plate (1) and pull out the shafts (2) with a puller bolt (3) 6 mm thread diameter

11. To remove the rocker arms from the cylinder head, first remove the rocker arm shaft retaining plate. Thread a 6 mm bolt into the rocker arm shafts and pull them out of the head (the cylinder head bolt is 6 mm and can be used for this operation). Mark each rocker arm and shaft for position and keep the pairs together so that each rocker arm can be installed on its proper shaft.

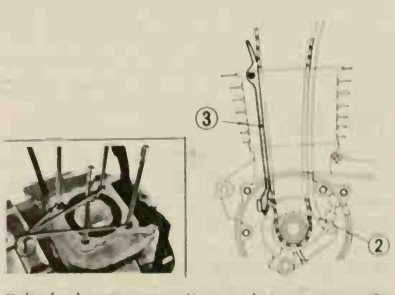


INSTALLATION

1. Install one wrist pin circlip and place the piston on the connecting rod noting that the "IN" stamped on the crown must be located on the intake port side or that the arrow points toward the exhaust port.

Install the wrist pin and the other circlip.

NOTE: *Always use new circlips; install them so that the end-gaps do not align with the cutouts on the piston.*



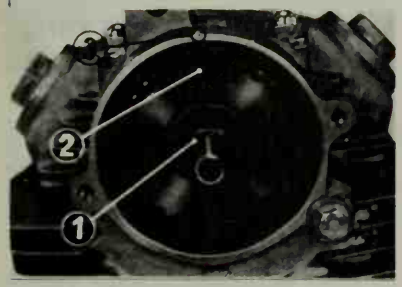
Arrange the ring end-gaps so that they are 120° apart, but none should be perpendicular to or parallel with the wrist pin. Lubricate the piston and rings with motor oil.

Top end assembly (100–125 cc, 1975 and earlier)

1. Valve adjusting cap	12. Rocker arm shaft retainer plate	23. Exhaust valve
2. Valve spring keeper	13. Camshaft	24. Intake valve
3. Valve spring retainer	14. Valve seal	25. Cylinder head gasket
4. Inner valve spring	15. Valve guide	26. Cylinder
5. Outer valve spring	16. Contact breaker housing	27. Top compression ring
6. Inner spring seat	17. Oil seal	28. Bottom compression ring
7. Outer spring seat	18. Spark advance mechanism	29. Oil ring
8. Valve guide	19. Breaker plate	30. Piston
9. Adjusting screw	20. Breaker points	31. Wrist pin
10. Rocker arm	21. Breaker cover	32. Wrist pin circlip
11. Rocker arm shaft	22. Cylinder head	33. Cylinder base gasket

2. Fit the cylinder base gasket. Make sure that all O-rings and locating pins are installed and lower the cylinder over the piston, compressing the rings with your fingers as the piston enters the bore. Pull the cam chain up through the cylinder. Install the cam chain guide.

Cylinder locating pins (1), cam chain tensioner (2), and chain guide (3)



3. Assemble the rocker arms in the head if removed. Fit a head gasket, and install the head. Pull the cam chain through and tie it aside. Fit the cam chain tensioner into its seat and install the tensioner mounting bolts.

4. Tighten the cylinder head capnuts and bolt in a cross pattern and in gradual increments until the proper torque of 13–14.5 ft lbs is reached.

5. Lubricate and install the camshaft. Arrange the cam so that the locating pin for the spark advance mechanism points upward.

6. Remove the alternator rotor cover and turn the crankshaft so that the "T" mark on the rotor is aligned with the mark on the stator. The piston is now at top dead center. Install the cam sprocket on the camshaft, looping the cam chain over it, so that the "0" mark on the sprocket is aligned with the mark on the top of the cylinder head. Be sure that the rotor "T" mark is still aligned. Fit the

camshaft sprocket bolts and tighten them to 6–9 ft lbs. These bolts should be secured with thread locking compound. The valve timing is now adjusted.

The "O" mark on the cam sprocket (2) must align with the mark (3) on the head with the piston positioned at TDC

7. The remainder of the procedure is the reverse of disassembly. Be sure to engage the slot in the timing advance mechanism with the pin in the camshaft. Adjust the cam chain, check ignition timing, etc., before starting the engine. Check cylinder head torque after the engine has been run and cooled off.

100/125 cc Models (1976)

1. The cylinder head on 1976 models has been modified to a two-piece type instead of the original single-piece casting. The head is now fitting with a cover secured by four allen bolts.

This change has been made to the following units: CB100E-1300001, CB125S-1300001 and subsequent.

2. Removal, disassembly, and installation of the top end components is performed in the same manner as for the 1975 and earlier engines. It is not necessary to remove the cylinder head cover in order to remove the camshaft or rocker arms. Its removal, however, may facilitate removal of valves and inspection of cam bearings.

3. Refer to 100/125 cc (1975 and Earlier) for procedures.

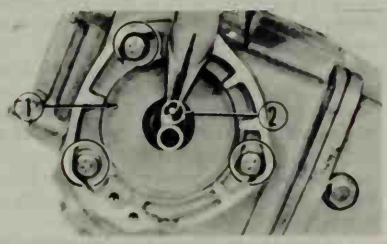
Specifications for the 125cc engine (1976) have been changed. Be sure to refer to the correct chart at the end of this section.

4. When assembling, be sure the oil seal rubber near the right-side cam bearing is in place. Use gasket sealer on the cylinder head cover mating surface.

90 cc Models

REMOVAL

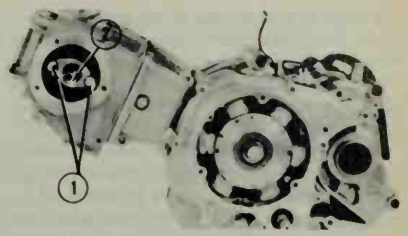
1. The cylinder head, cylinder, and piston may be removed with the engine still in the frame.



2. Remove the exhaust system and the carburetor manifold from the cylinder head.

3. Remove the valve adjustment caps; remove the breaker point cover.

4. Disconnect the point wire. Mark the position of the breaker plate relative to the point housing to facilitate ignition timing upon assembly. Remove the breaker plate screws and pull off the plate.



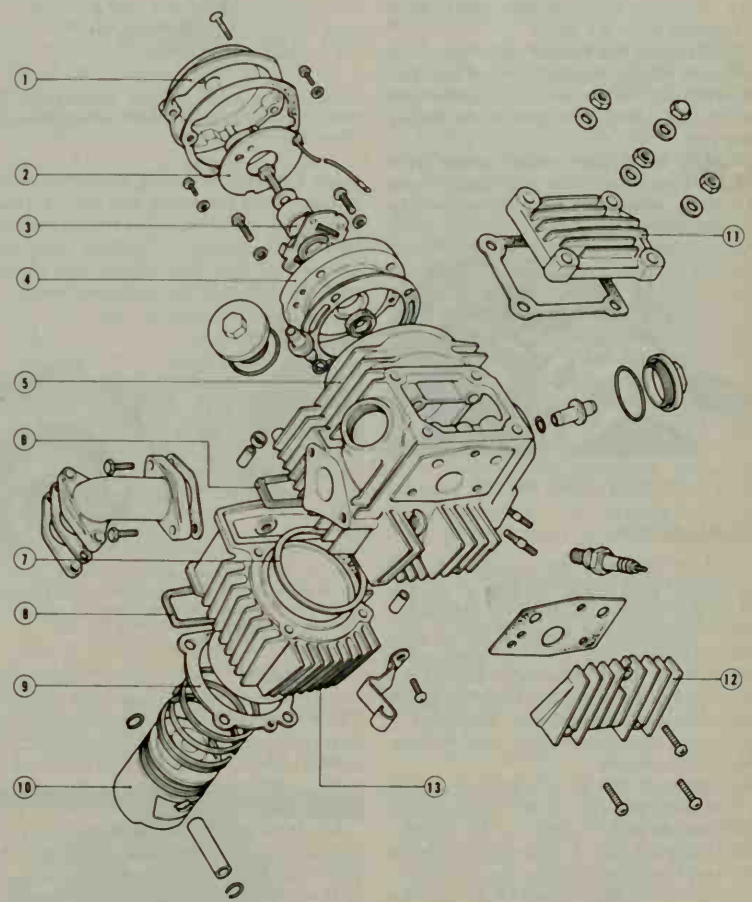
5. Remove the bolt from the end of the camshaft. Pull off the timing advance mechanism.

6. Remove the dowel pin from the camshaft. Remove the three phillips screws which secure the point housing to the head and remove the housing and its gasket.

Remove the camshaft dowel pin (2); then remove the three screws and the point housing

7. Rotate the engine so that the "0" mark on the cam sprocket aligns with the notch on the cylinder head. The sprocket bolts will be in line with the centerline of the cylinder.

Position the piston at TDC on the compression stroke before removing the head by aligning the sprocket "O" mark with the top of the head. The sprocket bolts (1) will align with the cylinder centerline as illustrated.



The piston is now at top dead center on the compression stroke.

8. Remove the two cam sprocket bolts.

CAUTION: *The cylinder head nuts must remain tightened when removing the sprocket bolts.*

9. Remove the camshaft. Take out the sprocket.

10. Loosen each of the four cylinder

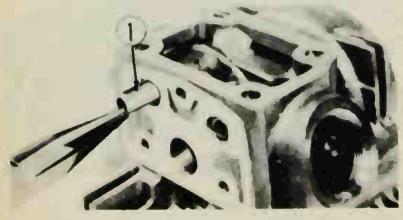
head nuts ¼ turn at a time in an "X" pattern until they are loose; then remove them. Lift off the cylinder head. Remove the gasket.

11. Remove the cam chain guide roller pin from the left-side of the cylinder.

12. Slowly pull off the cylinder, taking care that the piston does not strike the engine when the cylinder is removed.

13. After removing the cylinder, remove the piston wrist pin circlips with a needlenose pliers. Push out the wrist pin with a suitable drift.



Remove the cam chain roller pin (2) and the roller (1)

14. Remove the cylinder head cover and gasket from the head.

15. Remove the finned cover from the right-side of the head. Take off the gasket. Pull out the rocker arm shafts with needlenose pliers, and remove the rocker arms.

NOTE: *Keep the rocker arms with their respective shafts and install them in their original locations when the engine is assembled.*

Removing a rocker arm shaft

INSTALLATION

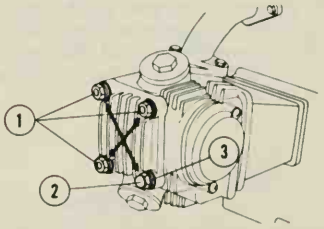
1. Use new wrist pin circlips. Install one circlip and place the piston on the rod so that the arrow mark on the piston crown is facing the front of the engine (exhaust side) or the "IN" stamped on the crown is on the intake side. Install the other circlip. Be sure that both are properly seated in their grooves. The gaps in the circlips should not align with the cutouts on the piston.

2. Arrange the piston ring end-gaps so that they are 120° apart, but none of them are at right angles to or parallel with the wrist pin. Lubricate the piston skirt and the rings with motor oil.

3. Clean off the cylinder base and the crankcase mating surface. Fit a new base gasket and a cam chain chamber gasket.

4. After ensuring that any cylinder guide pins or O-rings are in place, install the cylinder. As the cylinder is moved down on the studs, pull the cam chain through. Compress the piston rings carefully as the piston enters the bore. Place the piston at top dead center.

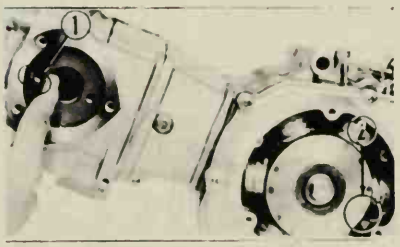
5. Install the cam chain guide roller and pin.



6. Assemble the cylinder head, refitting the rocker arms and shafts, the right-side cover and the top cover. Use new cover gaskets. Rocker arm shafts should be lubricated before installation.

7. Fit a new head gasket and upper cam chain chamber gasket. Fit the cam sprocket to the chain.

8. Install the head, drawing the cam sprocket up through the head as it is installed. Loop a length of wire through the sprocket and wire it to the head to keep it in place while torquing the head nuts.



9. Install and tighten the head nuts, noting that the lower left-hand nut is a capnut fitted with a copper washer.

Tighten the nuts in gradual increments in an "X" pattern until a final torque of 13–16 ft lbs is reached.

Torque the head nuts gradually and in an "X" pattern; be sure that the capnut (2) and copper washer (3) are in the right place

10. Check the timing marks on the alternator rotor ensuring that the "T" mark is aligned with the index mark (piston at top dead center). Position the cam sprocket so that the "0" mark is aligned with the notch in the cylinder head.

Line up the alternator rotor "T" mark with the crankcase mark (2), then position the cam sprocket so that the "O" mark is at the very top of the head (1) and aligned with the notch

11. Loosen the valve adjustment screws several turns. Install the camshaft. The dowel pin hole in the camshaft must face the notch in the cylinder head. Use thread locking compound on the sprocket bolts, tightening them to the proper torque.

12. Install a new oil seal into the point housing. Grease the lips of the seal before installing the housing.

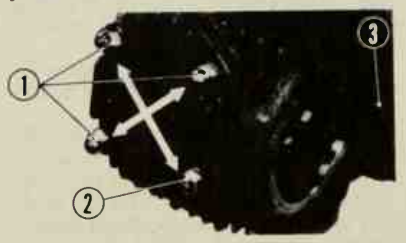
The use of a seal guide on the end of the camshaft is recommended to avoid damaging the lips of the seal when the housing is installed. (Tool No. 07043-1280100).

13. Install the housing, using a new gasket behind it. Install the dowel pin on the camshaft. Fit the spark advance mechanism, cam bolt, etc. The remainder of installation is the reverse of removal. Adjust the cam chain, valves, and ignition timing, and recheck these after a few miles of operation.

50–70 cc Models (Except XR75)

REMOVAL

1. The engine need not be removed from the frame to remove the cylinder head and cylinder. Remove the exhaust system and the carburetor and manifold from the cylinder.



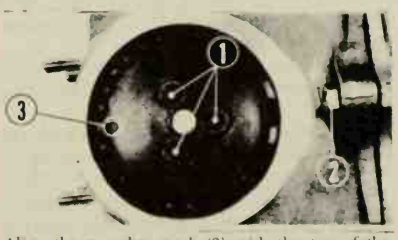
2. Remove the magneto or alternator rotor cover. Remove the spark plug and the valve adjuster caps. Turn the engine over until the intake valve goes down and comes up, and turn it a bit farther so that the "T" mark on the rotor aligns with the stationary index mark.

The piston is now at top dead center on the compression stroke (both valves closed).

3. Loosen each cylinder head cover nut ¼ of a turn at a time until they are loose, then remove them. Note that one or two of the nuts are different and must be installed in the location from which they were removed.

On most models, there is one hex nut and three capnuts; an oil sealing washer is fitted beneath the hex nut.

4. Tap the head cover lightly with a plastic mallet to free it if stuck.



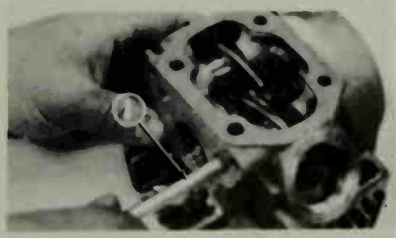
Remove the three capnuts (1), and the hex nut (2), to remove the cylinder head cover. Remove the head bolt (3) before attempting to remove the head (50-70 cc)

5. Remove the bolt from the right-side of the cylinder head. This will enable the left-side cover to be removed.

6. Remove the two screws on the right-side cylinder head cover and remove the cover.

7. Check that the piston is at TDC (the "0" mark on the cam sprocket will be toward the top of the head).

8. Remove the three sprocket mounting bolts, and push in on the camshaft to disengage it from the sprocket. Remove the sprocket after disengaging it from the cam chain.



Align the sprocket mark (3) with the top of the head before removing the sprocket bolts (1)

NOTE: *It may be necessary to hold the camshaft in position while removing*

the sprocket bolts and this can be done if the engine is in the frame by engaging the transmission except for centrifugal clutch models. If the engine is not in the frame, secure the magneto rotor or the countershaft sprocket.

9. Remove the cylinder head mounting bolt on the left-side of the head. Remove the head, tapping around the mounting surface with a plastic mallet if it is stuck.

10. When the head is removed, remove the two locating pins at the head mating surface and ensure that they are in place when the head is refitted. To

Removing the rocker arm shaft with a 6 mm puller bolt

remove the rocker arms, thread a 6 mm bolt into the right-side of the rocker arm shafts and pull them out. Keep each rocker arm shaft with its own rocker arm for proper installation. Push the camshaft out of the head.

NOTE: *The cylinder head or cylinder mounting bolt can be used to remove the rocker arm shafts.*

11. Unscrew and remove the cam chain guide roller pin from the left-side of the cylinder and remove the guide roller.

Removing the cam chain guide roller pin (1)

12. Remove the cylinder mounting bolt on the left-side and pull off the cylinder. Do not allow the piston to strike the studs as it comes out of the cylinder. Check the location of the two hollow dowel pins on the cylinder studs. Remove these and make sure that they are installed when assembling the top end.

13. To remove the piston, remove the wrist pin circlips with needlenose pliers and push out the wrist pin.

NOTE: *Use steady pressure while removing the wrist pin. Support the piston with your other hand. Do not strike or attempt to force out the pin.*

INSTALLATION

1. Install one wrist pin circlip and place the piston on the connecting rod. The triangular mark on the piston crown must be positioned on the *cam chain* side. Insert the wrist pin and the other circlip. Use new circlips and be sure that they are properly seated. Arrange the circlip end-gaps so that they do not align with the cutouts on the piston. Arrange the piston rings so that the end-gaps are 120° apart, but are not perpendicular to or parallel with the wrist pin. Lubricate the wrist pin, rings, and piston skirt with motor oil.

2. Be sure that the O-ring is in place in the crankcase oil passage and the hollow dowel pins are installed on the cam chain side studs. Fit a new cylinder base gasket. Install the cylinder, compressing the rings with your fingers as the piston enters the bore. Feed the cam chain through the cylinder as it is seated. Install and tighten the cylinder mounting bolt.

3. Install the cam chain guide roller and the roller pin.

4. Install the two hollow pins on the studs: one on the top right stud, the other on the left bottom. Fit the O-rings to the oil passage and to the stud oil passage; fit the head gasket.

5. Install the head, complete with rocker arms and cam, threading the cam chain with its sprocket through, and securing them with a length of wire or a screwdriver.

6. Turn the magneto rotor so that the "T" mark on the rotor is aligned with the index mark on the crankcase. Set the cam sprocket "0" mark at the top of the head. Install and tighten the sprocket bolts to 4–7 ft lbs. Thread locking compound should be used on these bolts. Lubricate the top end components.

7. The remainder of the procedure is the reverse of disassembly. Note that the cylinder head cover hex nut (on most models) and its copper washer are installed on the lower left stud. Install the head mounting bolt. Tighten the head cover nuts in a cross pattern and in increments of 2–3 ft lbs until the proper torque of 6.5–8.7 ft lbs is reached. Adjust the cam chain and tappet clearance before starting the engine.

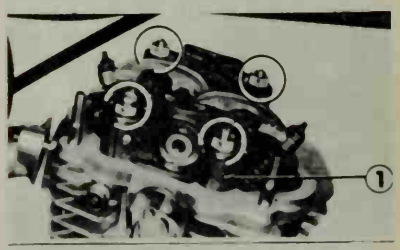
XR75

REMOVAL

1. The top end can be removed with the engine in the frame. Remove the gas tank, exhaust system, carburetor, and manifold.

2. Remove the magneto rotor cover. Remove the spark plug.

3. Remove the cylinder head cover.



Cam sprocket positioned for removal. Note "O" mark on the sprocket (1) and the cam housing mark (arrow). Sprocket bolts (2 and 3) are not interchangeable.

4. Turn the engine over until the "0" mark on the cam sprocket is aligned with the mark on the cam housing. Unscrew and remove the two cam sprocket bolts.

NOTE: *The bolts are not interchangeable. Mark the location of each so that they can be installed in their original locations.*

5. Remove the cam sprocket. Loop a length of wire around the chain and secure it so that it doesn't fall into the cylinder.

6. Remove the three hex nuts and one capnut and take off the camshaft housing complete with cam and rocker arms.

Remove the camshaft housing (1) after removing the four nuts circled

7. Thread an 8 mm bolt into the rocker arm shafts and pull them out. Mark each and the rocker arms for proper installation. Remove the cam.

8. Remove the cam chain tensioner set plate bolt from the cylinder head. Pull out the tensioner adjuster.

9. Remove the cylinder head. If stuck, strike carefully with a plastic mallet. When removing the head, be sure that the cam chain does not fall into the crankcase.

Note the location of the dowel pins and O-rings on the head-cylinder mating surface. Be sure that they are correctly installed when assembling the engine.

10. Remove the cam chain guide. It can be pulled out of the cylinder. Loosen the cam chain tensioner bolt.

11. Remove the cylinder. When the cylinder is lifted off the crankcase, stuff a clean rag between the cylinder and case to catch any pieces of broken ring, dirt, etc.

Note the location of any dowel pins or O-rings between the cylinder and the case. These must be in their proper locations when assembling the engine.

12. Remove the wrist pin circlips with needlenose pliers.

NOTE: *Keep the rag in place while doing this.*

13. Push out the wrist pin. If the pin resists removal, the piston crown may be heated gently with a propane torch.

CAUTION: *Never strike the wrist pin to remove it. Use steady pressure only. Support the piston with one hand while the wrist pin is removed.*

INSTALLATION

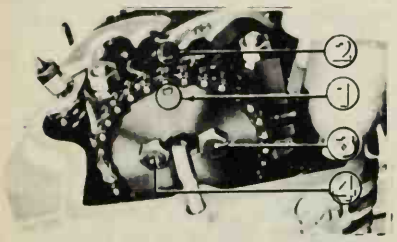
1. The piston must be installed so that the "IN" marking on the crown is on the intake side. Use new wrist pin circlips.

Circlips should be firmly seated in their grooves. The open ends should not align with the piston cutout.

2. Arrange the piston rings so that the end-gaps of the two compression rings and the oil ring expander are 120° apart. Arrange the end-gaps of the two oil rails about 45° on either side of the expander end-gap.

None of the ring end-gaps should be perpendicular to or parellel with the wrist pin.

3. A new cylinder base gasket must be used. Be sure that any dowel pins or O-rings are in place before installing the cylinder.



4. Lubricate the piston assembly with motor oil before fitting the cylinder. Pull the cam chain through the cylinder as it is installed. Install the chain guide.

5. Use a new head gasket. Install the head, making sure that any dowel pins or O-rings are in place.

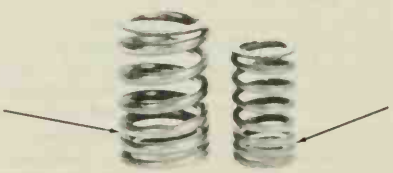
6. Install the cam housing, cam, and rocker arms in the head. Turn the cam so that both valves are closed. Clean the threads of the cylinder studs, and oil them lightly. Fit the cam housing nuts, and tighten them in a cross pattern until the correct torque (5.8–8.7 ft lbs) is reached.

7. Remove the rotor cover. Turn the engine over until the "T" mark on the rotor aligns with the index mark.

8. Install the cam sprocket so that the "0" mark on the sprocket aligns with the mark on the cam housing.

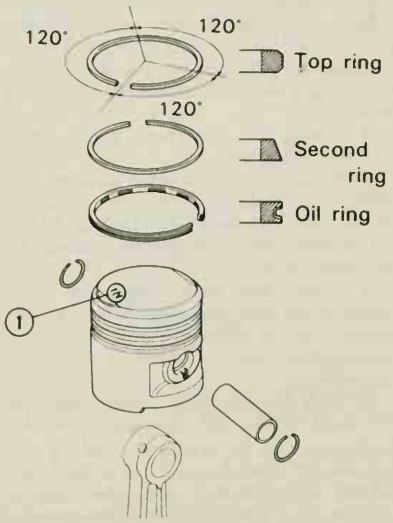
With the piston at TDC, align the sprocket mark (1) with the housing mark (2), then install the bolts (3 and 4)

9. Fit the sprocket bolts, noting their proper locations. Use thread locking compound on these bolts. Torque to 5.8–8.7 ft lbs.



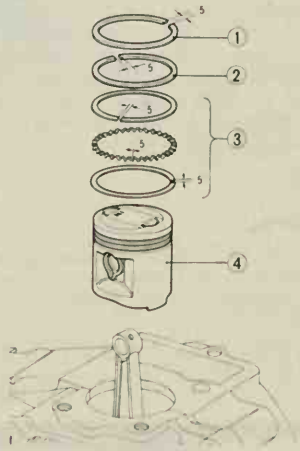
10. The remainder of the procedure is the reverse of removal. Adjust the cam chain and valve clearance before starting the engine.

TOP END SERVICE



Service and inspection procedures for the components in the top end are outlined in the "Engine Rebuilding" section in "General Information," while specifications for individual models are given in the specifications charts at the end of this section; however, note the following:

1. Early model 100s (up to Frame No. 200000) were equipped with straight-wound valve springs. If the later progressively-wound springs are fitted as a replacement, they must be replaced in sets.



2. Some models use stellite-tipped valves. Attempting to resurface the valve stem will wear away the hardened stellite surface.

Progressively-wound valve springs are installed with the close coils against the head

Ring end-gaps should be spaced 120° apart. The piston must be installed so that the "IN" mark is toward the intake side on the head. Note the difference between the top and bottom compression rings.

On models with multi-piece oil rings, the end-gap of the expander should be 120° from the lower compression ring, and the two oil rail end-gaps should be about 45° on either side of the expander end-gap

3. Before installing the rings on the piston, first note that the two compression rings are not interchangeable in most cases. The wedge-shaped ring is the lower compression ring.

Also note that rings must always be installed so that the manufacturer's mark (the small letter near the end-gap) faces *up* when the rings are in place.

4. If two-rail oil rings are used, install one rail on the piston below the oil ring groove. Install the oil rail expander in the groove, than move the lower rail into the groove. Install the upper oil rail.

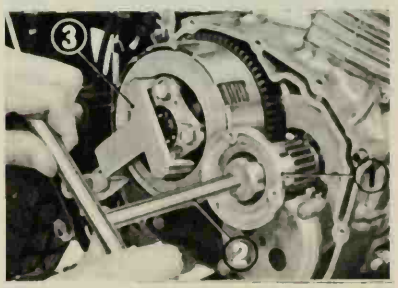
5. Arrange the ring end-gaps 120° apart, but do not position any end-gap at the very front or the very back of the piston (perpendicular to the wrist pin), or directly above the wrist pin holes.

If a two-rail oil ring is used, position the end-gap of the oil ring expander 120° from the lower compression ring, then position the end-gaps of the oil rails about 45° (20–30 mm) on either side of the expander end-gap.

CRANKCASE COVER COMPONENTS

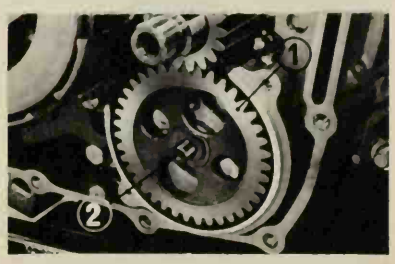
Right Crankcase Cover Components

100–125 CC MODELS



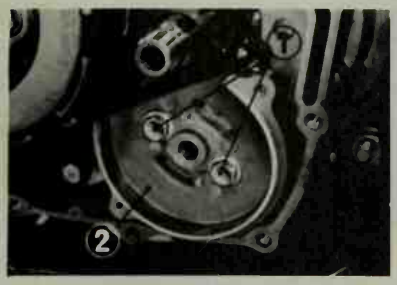
Clutch, oil pump and filter, and the gearshift mechanism are accessible after removing the right crankcase cover. To remove the kick-starter, it is necessary to split the cases. Refer to "Lower End and Transmission."

Removal and Installation



1. Drain the oil. Remove the exhaust system and the right footpeg. Remove the kick-starter lever. Disconnect the clutch cable, and the tach cable, if fitted. Remove the right crankcase cover.

2. Remove the oil filter rotor cap (three screws). Remove the rotor nut. A special wrench is needed to remove the nut. Remove the rotor.



3. Remove the oil pump gear cover. Remove the oil pump gear and shaft. The oil pump is secured by two bolts. Remove them and remove the pump.

4. Gradually loosen the clutch lifter plate bolts, then remove the bolts along with the lifter pin, lifter plate, lifter bearing, and springs.

5. Remove the crankshaft primary gear. Remove the clutch hub snap-ring, housing as a unit. The clutch lever in the right cover on TL125 and 100/125(76) can be removed after removal of the cotter pin. Be sure the spring is correctly installed.

6. To remove the gearshift linkage, remove the circlip on the shift shaft and remove the shift plate from the shaft.

7. Remove the gearshift drum stopper and spring. Remove the shift drum stopper plate. Both of these parts are secured by single bolts.

8. Remove the gearshift lever (left-side). Pull the gearshift shaft out from the right-side.

9. Refer to "Component Inspection," which follows.

10. Assembly is the reverse of the above. Note the following points:

a. The stopper plate is equipped with a locating pin hole. Match it with the pin in the shift drum. Install the gearshift shaft so that the ends of the shaft return spring are located on either side of the boss on the crankcase;

b. Tighten the clutch lifter plate bolts progressively until a torque of 5.6–8.7 ft lbs is reached;

c. Before installing the oil pump, be sure that the O-rings are installed;

d. When installing the oil filter, note that the rotor washer is marked for proper installation. The "outside" side of the washer must face out. Tighten the rotor nut to 29–36 ft lbs.

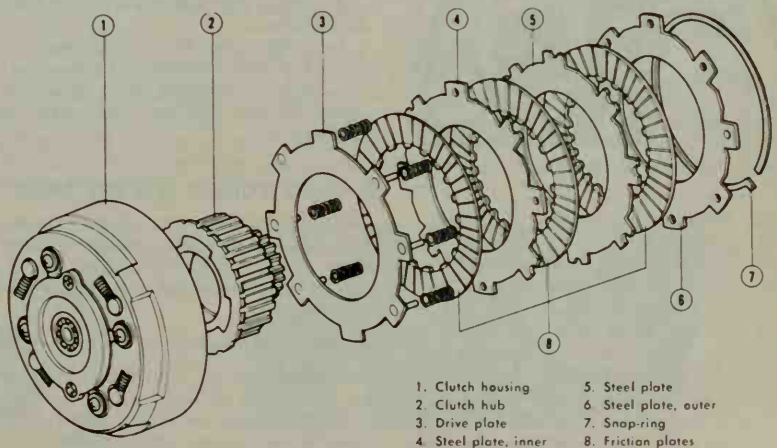
90CC MODELS

Clutch, oil pump, primary driven gear, and the gearshift mechanism are accessible after removing the right-side cover. To remove the kick-starter mechanism, it is necessary to split the cases. Refer to "Lower End and Transmission."

Removal and Installation

1. Drain the oil. Disconnect the clutch cable from the lever at the engine (if fitted).

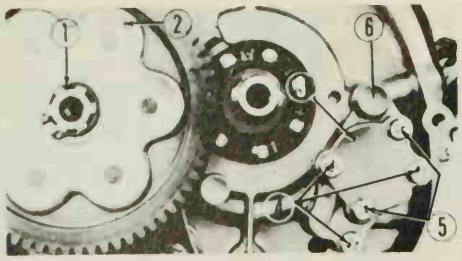
2. On models with a tubular sub-frame (ST/CT models), remove the foot-pegs and the sub-frame.



3. Slack off the rear brake adjuster nut several turns. Remove the pinch-bolt and pull off the kick-starter.

4. Remove the clutch cover plate. Remove the right crankcase cover. Remove and discard the cover gasket.

5. On centrifugal clutches, remove the clutch lifter lever and the lifter.



6. Remove the clutch housing cover usually secured by two phillips screws.

7. Bend down the tab on the clutch

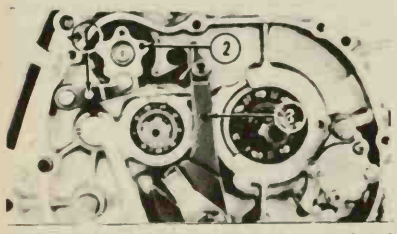
8. If disassembly of the clutch is required, compress it using the special Honda tool, or compress the assembly is a soft-faced vise. Remove the large snap-ring on the inner side. Carefully remove the clutch from the vise or tool (it is under spring pressure when compressed), and separate the components: steel and friction plates, free springs (centrifugal clutch), clutch hub, and gears.



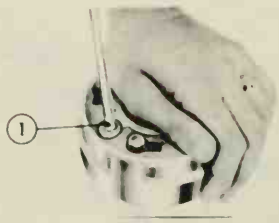
If further disassembly is desired, remove the clutch damper springs in the clutch housing. Remove the phillips screws from the outer side of the housing and separate drive plate, clutch springs, and housing.

To complete disassembly, remove the clutch weight stopper ring from the drive plate.

9. Remove the oil pump by removing the hex bolt and three phillips screws. Remove the oil filter screen.

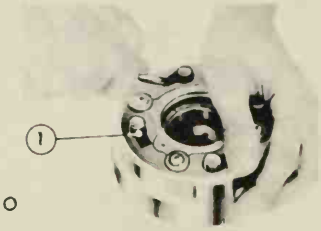
10. Remove the snap-ring to remove the large primary driven gear.

11. Remove the pinch-bolt and pull the foot gearshift lever off the splined shift shaft. Remove the shift drum stopper. Disengage the fingers of the shift arm from the shift drum pins and pull the shift shaft assembly out of the case. Remove the phillips screw and the shift drum stopper plate (if desired).



Shift drum stopper (1), stopper plate (2), and shift arm (3)

12. Refer to "Component Inspection," which follows.



13. Installation is the reverse of removal. Note the following points:

a. To assemble the clutch, first assemble the drive plate and spring assembly. Place the clutch housing over it and compress both as shown while fitting the housing phillips screws;

b. Use the special tool or a substitute to compress the clutch assembly while the snap-ring is fitted;

Assembling the clutch

Installing the damper springs

c. Install the damper springs with a screwdriver as illustrated;

d. The shift drum stopper plate must be firmly secured. Use an impact driver or thread locking compound to tighten it;

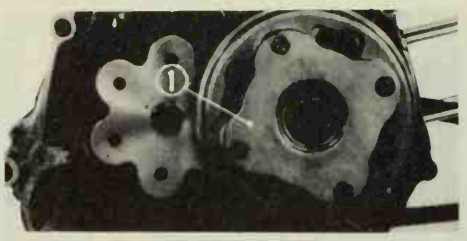
e. Be sure that the gearshift lever return spring pin is secured in the crankcase. Install the gearshift shaft assembly, locating the ends of the return spring on either side of the stopper pin and engaging the fingers of the shift arm with the shift drum pins;

f. Install the shift drum stopper, so that the roller bears against one of the detents of the shift drum stopper plate;

g. Check the operation of the shift mechanism;

h. Torque the hub nut to 54–64 ft lbs. Bend up the tab on the lockwasher;

i. Before refitting the crankcase cover, be sure that the dowel pins are in place.

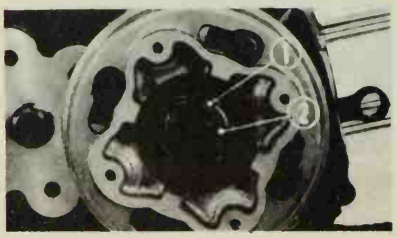


50–70CC MODELS (EXCEPT XR75)

The clutch, oil pump, primary driven gear, gearshift assembly, and kick-starter return spring and spring retainer are accessible after removing the right crankcase cover.

Removal and Installation

1. Drain the oil. Remove the crankcase bash plate (if fitted).



2. Disconnect the clutch cable at the engine lever (manual clutch models); remove the kick-starter lever.

Clutch cover (50-70 cc)

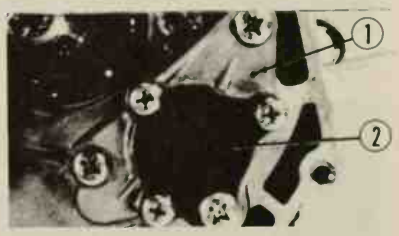
3. Take out the screws and remove the right crankcase cover.

NOTE: *On most models the cover screws are of different lengths; note their locations to install properly. Note the dowel pins between the case and cover.*

Bend up the tab of the lockwasher (1) to remove the clutch hub nut (2)

4. On centrifugal clutches, remove the clutch lifter lever and the lifter.

5. Remove the clutch housing cover.



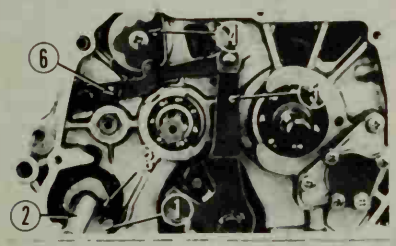
6. Bend down the tab on the clutch nut lockwasher. Remove the clutch hub nut with the special wrench. The crankshaft must be secured while doing this.

Remove the clutch assembly from the crankshaft.

7. If disassembly of the clutch is desired, compress it using the special Honda tool, or compress the assembly in a soft-faced vise. Remove the large snap-ring on the inner side. Carefully remove the clutch from the vise or tool (it is under spring pressure when compressed) and separate the components: steel and friction plates, free springs (centrifugal clutch), clutch hub, and gears.

If further disassembly is desired (centrifugal clutches), remove the clutch damper springs in the housing. Remove the phillips screws from the outer side of the housing and separate the drive plate, clutch springs, and housing.

8. Remove the three oil pump mounting screws to remove the oil pump. Remove the filter screeen.



Oil pump (1) and cover (2)

9. Remove the circlip to remove the large primary driven gear. Remove the circlip from the kick-starter shaft. Detach the kick-starter return spring from the

crankcase, and remove the spring and retainer.

10. Remove the shift drum stopper and spring. Remove the gearshift lever from the left-side of the engine. Loosen the shift drum stopper plate screw, disengage the fingers of the shift arm from the shift drum dowel pins, and pull the gearshift shaft out of the crankcases.

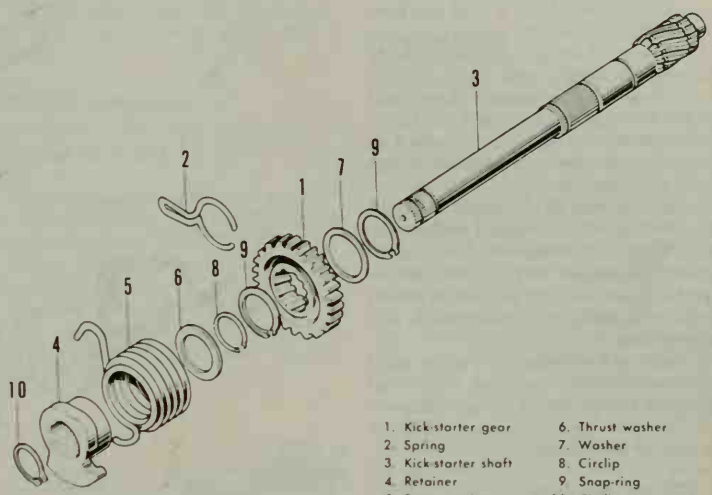
12. Installation is the reverse of removal. Note the following points:

a. The shift drum stopper plate screw should be secured with thread locking compound or an impact driver;

b. Be sure that the gearshift lever return spring pin is secured in the crankcase. Install the gearshift shaft assembly, locating the ends of the return spring on either side of the stopper pin and engaging the fingers of the shift arm with the shift drum pins;

c. Install the shift drum stopper, so that the roller bears against one of the detents of the shift drum stopper plate;



d. Check the operation of the shift mechanism;

e. Install the kick-starter return spring and spring retainer. One end of the spring should engage the crankcase, and the pawl on the retainer should rest against the stopper boss of the crankcase. Install the kick-starter shaft circlip;

f. The collar installed on the crankshaft behind the clutch is fitted with the larger diameter side toward the engine. The clutch should be assembled before fitting it to the crankshaft;

g. Tighten the clutch nut to 27.5–32.5 ft lbs, and bend down the tab on the lockwasher;

Removal and Installation

1. Drain the oil. Remove the exhaust pipe. Remove the kick-starter arm. Disconnect the clutch cable from the lever at the engine.

2. Remove the skid plate and footpeg.

3. Remove the right crankcase cover screws and tap lightly on the cover with a plastic mallet to free it if necessary.

4. Remove the oil filter screen.

5. Remove the centrifugal oil filter rotor cover (three screws), and remove the rotor nut with the special wrench. Keep the crankshaft from turning by jamming the primary gear with a block of hardwood, or by engaging the transmission and applying the rear brake.

6. Remove the rotor and the primary gear.

7. Remove the oil pump gear cover, then the pump assembly.

8. Remove the clutch lifter plate bolts, loosening them evenly. Remove the clutch lifter plate and springs.

9. Remove the circlip from the clutch shaft, and take out the clutch hub and plates as an assembly.

10. Remove the splined washer and the clutch housing.

11. Remove the shift drum stopper. Remove the stopper plate.

12. Remove the gearshift lever from the left-side of the engine. Pull out the shifter return spring and shaft from the right-side. Do not lose the small shifter damper spring.

13. Refer to "Component Inspection," following.

14. Assembly is the reverse of the above.

Note the following points:

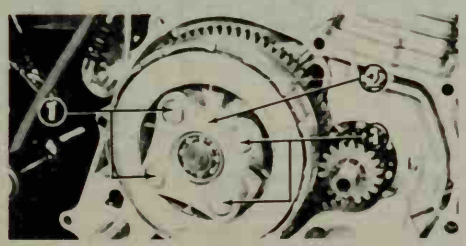
a. Check the stopper and stopper plate for proper operation after tightening the bolts;

b. Be sure to fit the splined washer to the clutch shaft after installing the housing;

c. The oil pump O-rings and gasket should be replaced with new ones. The gasket must not contact the rotor. Do not forget to install the tach gear thrust washer;

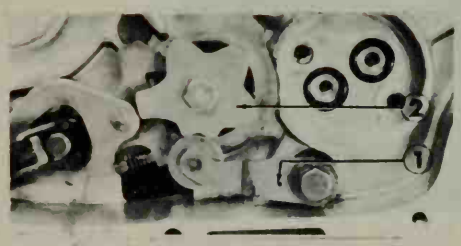
d. Tighten the clutch bolts gradually and evenly. Adjust the clutch after assembly.

Left Crankcase Cover Components



The left crankcase cover contains the alternator or magneto, the countershaft sprocket, and the cam chain tensioner on some models.

All components can be removed for service with the engine in the frame.



Certain precautions should be observed when handling these components:

a. The rotor must be removed with a special puller. Do not attempt to pry the rotor off the tapered crankshaft;

b. Do not heat or strike the rotor as this may affect its magnetic properties;

Clutch lifter plate (2) and bolts (1)

Shift drum stopper (1) and stopper plate (2)

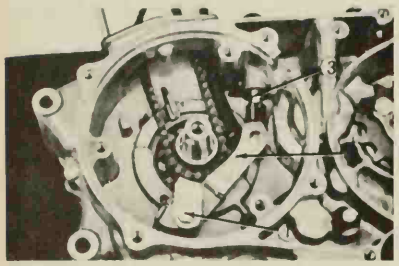
e. Do not drop the rotor once it is removed. Place it where it will not pick up stray bits of metal;

d. Be sure that the rotor is perfectly clean before installation. Push it on its shaft (note the woodruff key) and tighten the rotor bolt or nut to seat it. Do not strike it. Some oil applied to the crankshaft taper will facilitate future removal of the rotor;

e. Be sure that all electrical wiring is properly routed and seated in the rubber grommets provided before installing the crankcase covers. Be certain that the cover will not pinch the wires, or that the wiring will not touch any moving part;

f. Be sure that parts such as the rotor and countershaft sprocket bolts are tightened to the proper torque. Refer to the "Torque Specifications" chart at the end of this section.

100–125 cc Models

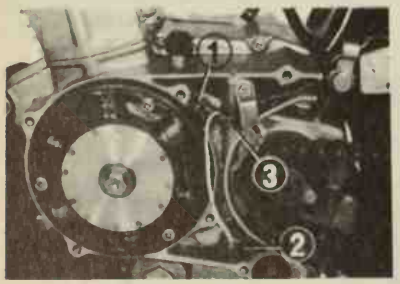


REMOVAL AND INSTALLATION

1. Drain the oil. Remove the alternator wiring at the plastic coupler. Remove the gearshift lever.

2. Remove the alternator rotor cover. Remove the countershaft sprocket cover. Disconnect the neutral switch wire if fitted. Remove the forward section of the left crankcase cover.

3. Remove the screws securing the alternator stator. Secure the rotor, and remove the rotor bolt. Using the special puller, remove the rotor.



4. Early models: remove the cam chain tensioner arm pivot bolt, and take out the tensioner components.

6. Remove the tensioner arm pivot bolt, and the arm and roller.

7. Remove the countershaft sprocket bolts, disconnect the chain, remove the sprocket locking plate, and pull off the sprocket.

NOTE: *On models with a full-coverage chain guard, wire the ends of the chain together to keep them from falling into the chaincase.*

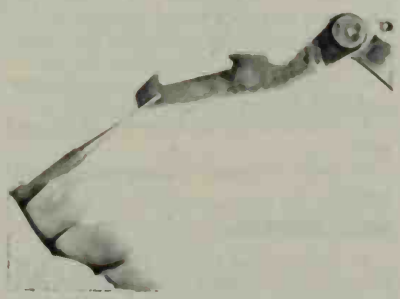
8. Refer to "Component Inspection," following.

9. Installation is the reverse of the above. Note that the O-rings in the stator plate screw holes, the plate O-ring and the crankshaft oil seal must be in place.

Component Inspection

NOTE: *Where necessary, refer to the specifications charts at the end of this section for wear limits and tolerances.*

CLUTCH



Clutch component inspection procedures are outlined in "Engine Rebuilding." Specifications for individual models are given in the charts at the end of this section.

GEARSHIFT LINKAGE

Note those procedures applicable to the type of shift linkage fitted to your model.

1. Check the splines on the gearshift shaft. If the splines are broken or torn to such an extent that it is difficult to properly secure the shift lever, replace the shaft.

2. 50–90 cc: Check the condition of the shift arm. Be sure that it is not bent. Check that the shift fingers are not bent or worn.

Check the shift arm fingers for damage

3. Check the condition of the springs in the shift linkage, especially the shift lever return spring. If any spring has lost its tension, or fails to hold its component properly, replace it.

4. 100–125 cc: Check the inner surfaces of the shift plate for wear caused by contact with the shift drum stopper plate pins. Replace the shift plate or stopper plate if wear is evident.

5. Check the condition of the shift drum stopper roller and replace it if worn. The stopper spring should hold the stopper firmly against the stopper plate.

6. Check the shift drum stopper plate and pins for wear. Replace if damaged.

KICK-STARTER

50–70 cc Models

1. Check the splines on the kick-starter shaft and replace the shaft if they are torn or will not secure the starter lever properly.

2. Check that the return spring retainer is not chipped and that its splines are not damaged.

3. The kick-starter return spring must be able to return the kick-starter lever to its stop and hold it there. If weakened or broken, replace it.

Other kick-starter components are accessible only after splitting the crankcases. Refer to that section.

OIL PUMP

Test procedures can be found in the "Lubrication Systems" section. When installing the pump or related parts, new O-rings and gaskets should always be used.

ALTERNATOR

1. For electrical tests, refer to the "Electrical Systems" section.

2. Check the rotor and stator for signs of wear. If there has been contact between the rotor and the stator assembly, this condition must be rectified. In addition, the components should be tested to make sure that they still operate properly. Check the stator for foreign matter on the poles, burnt wiring, damaged insulation, etc.

3. Check that the stator assembly is securely mounted, and properly aligned. If the rotor has contacted the stator, check for play in the crankshaft. This condition may sometimes be caused by a bad crank bearing.

4. Remove any rust or corrosion from the crankshaft taper. Check the woodruff key for step-wear.

5. Check that the rotor has little or no run-out as it turns. If run-out exists, determine the cause.

6. If scoring on either the rotor or the stator components is severe, the part(s) should be replaced.

MAGNETO

1. For electrical tests, refer to the "Electrical Systems" section.

2. Check the inside of the rotor and the coil core ends for scoring which would indicate that they have been in contact. This condition must be rectified.

3. Check that the coils are securely mounted to the stator plate. Check that the plate is securely mounted. If the stator coils and rotor have been in contact, check for play in the crankshaft. This condition is sometimes caused by a bad crank bearing.

4. Check the rotor for cracks, especially on the tapered mount. Check that the timing advance mechanism (if fitted) functions properly. When the breaker cam is turned, the springs should have enough tension to return it to its original position easily.

5. Check the coils for broken or burned wiring, bad insulation, etc.

COUNTERSHAFT SPROCKET

1. Check the teeth of the sprocket and ensure that they are not hook-shaped, broken, or worn. If any wear is in evidence, the sprocket should be replaced, and the chain and rear wheel sprocket closely inspected for condition.

2. Check the rotational play of the sprocket on the countershaft. The sprocket splines should not show signs of wear. Replace the sprocket if it is not a firm fit on the shaft.

CRANKCASE COVERS

1. Always use new crankcase cover gaskets where they are fitted.

2. Remove any nicks or imperfections from the mating surfaces with an oilstone or silicon carbide paper.

3 Oil seals, where fitted, can be pried out. When fitting new seals, press them in with a block of wood or something similar which will cover the whole seal.

Press seals straight in until seated. Grease the seal lips before installation.

4. On some models, clutch lifter levers are fitted into the right crankcase cover. The levers can be pulled out after removing the pin which secures them to check the O-ring and spring.

5. Crankcase covers may be fitted with one or more hollow locating pins. These must be installed before the cover is fitted.

SUB-TRANSMISSION (CT90)

1. Check the condition of all the gear teeth for wear, pitting, or cracks. Pay close attention to the base of each tooth, since this is where most damage shows up.

2. Check the engaging dogs on the sub-trans High gear for wear or chipping. Inspect the corresponding holes in the Low gear as well.

3. Check the splines on the gears and the countershaft sprocket for wear or damage.

4. Check the condition of the shift fork fingers. They should be straight and the tips must be undamaged. To remove the shift fork shaft, pull it out. Note the steel ball and spring which locates the fork on the shaft.

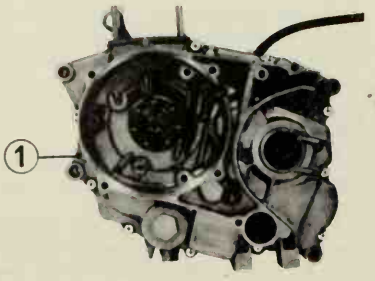
Check the shaft for wear or discoloration. Be sure that the bore of the fork is without score marks.

To install the shaft into the fork, insert the spring and ball, and use a thin screwdriver through the hole in the fork to push down the ball so that the shaft can be inserted.

5. Check the condition of the countershaft ball bearing. Rotation of the bearing must be smooth and without binding. If necessary to remove the bearing, heat the cover slightly and tap out the bearing.

6. If leakage is noted from the sub-trans shift lever, remove the securing clip on the inside of the cover, and pull out the shift lever. Replace the O-ring on the shift lever shaft.

7. Installation is the reverse of removal. Use a new cover gasket. Be sure that the locating pin is in place for the upper right-hand cover screw. Note that this screw is threaded for its entire length.



LOWER END AND TRANSMISSION

Splitting the Crankcases

100–125 CC MODELS

1. Remove the engine from the frame. Remove the cylinder head, cylinder, and piston. Remove the left and right-side covers and the components therein. Refer to the preceding sections for procedures.

2. Loosen the screws securing the crankcase halves (one screw is in the right case, the remaining 10 are in the left), with an impact driver. Remove the screws. Separate the case halves. The crank and transmission will remain in the right case half.

Crankcase screws (100-125 cc)

NOTE: *If the cases are stuck, they may be freed by tapping very gently with a plastic mallet. Do not strike the crankshaft or transmission shafts.*

3. Remove the case gasket. Exercising care, tap the crankshaft out of the case. The case may be heated slightly with a propane torch in the vicinity of the crankshaft bearing boss to facilitate removal.

4. Carefully remove the gear clusters and shift drum assembly as a unit.

5. Pull out the kick-starter shaft and gears.

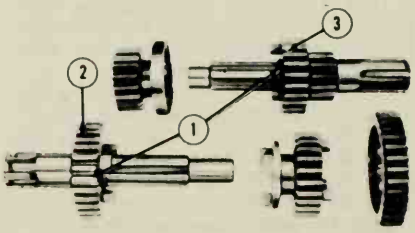
6. Refer to inspection procedures following.

90CC MODELS

1. Remove the engine from the frame. Remove the cylinder head, cylinder, and piston. Remove the left and right crankcase covers and remove the alternator stator and rotor, the countershaft sprocket, clutch, primary driven gear, gearshift shaft, cam chain, etc. Refer to the preceding sections for procedures. The oil pump need not be removed.

2. Remove the shift drum bolt on the left case half. Remove the screws in the right crankcase half. Tap around the mating surface with a plastic mallet and separate the case halves. Remove the case gasket.

The crankshaft and gear assemblies will remain in the left case half.



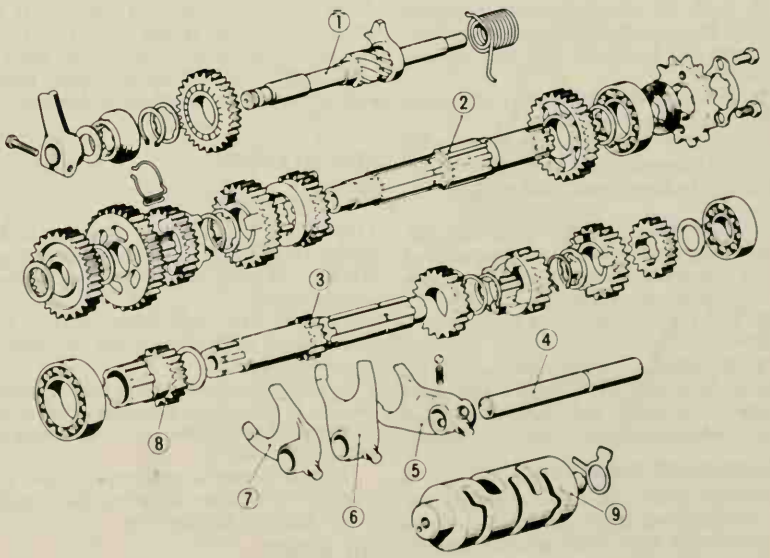
Gearshift drum bolt (1) (90 cc)

CAUTION: *Do not strike the ends of the crank or transmission shafts to separate the cases.*

3. Remove the kick-starter shaft from the right case half (new type) or left half (older type).

4. Remove the crankshaft from the left case half. The case may be heated gently with a propane torch in the vicinity of the bearing boss to facilitate removal.

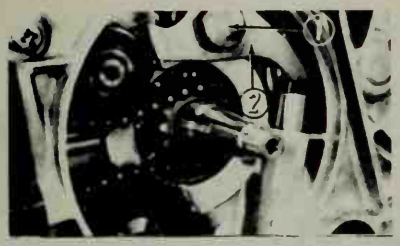
5. Remove the gear clusters and shift drum.



Transmission components (ST90): snap-ring (1); countershaft Third gear (2); mainshaft High gear

6. Refer to inspection procedures following.

50–70CC MODELS (EXCEPT XR75)



1. Remove the engine from the frame. Remove the cylinder head, cylinder, and piston. Remove the left and right-side covers and the components therein.

Refer to the preceding sections for procedures.

1. Kick-starter shaft
2. Countershaft
3. Mainshaft
4. Shift fork shaft
5. Left shift fork
6. Center shift fork
7. Right shift fork
8. Kick-starter gear
9. Shift drum

Tensioner arm pivot bolt (1) and arm (2) (50-70 cc)

2. Unscrew and remove the cam chain tensioner pushrod bolt, and remove the pushrod assembly. Remove the tensioner arm pivot bolt, and remove the arm and roller assembly.

3. Remove the shift drum bolt beneath the rubber plug on the left crankcase half. Remove the eight crankcase screws on the left case half.

The screws are of three different lengths. Note their location as they are removed.

4. Separate the cases. The crank and transmission will remain in the left half.

NOTE: *If the cases are stuck, they may be freed by tapping very gently with a plastic mallet. Do not strike the crankshaft or transmission shafts.*

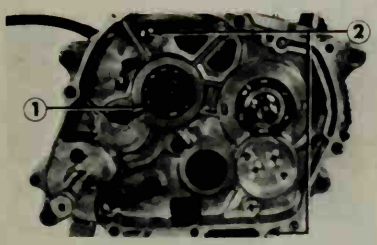
5. Remove the case gasket. Pull out the kick-starter shaft assembly.

6. With care, tap the crankshaft out of the case. The case may be heated slightly with a propane torch in the vicinity of the crankshaft bearing boss to facilitate removal.

7. Very carefully remove the gear clusters and shift drum assembly as a unit.

8. Refer to the inspection procedures following.

XR75



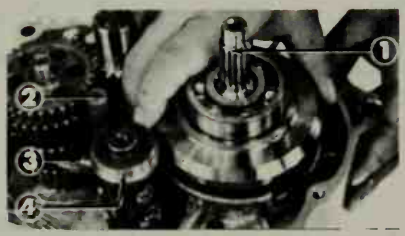
1. Remove the engine from the frame.

2. Remove the top end assembly: cylinder head, cylinder, and piston.

3. Remove the oil filter rotor and the oil pump. Remove the clutch, gearshift linkage, stopper arm and plate, magneto, and countershaft sprocket.

Refer to the preceding sections for procedures.

4. Remove the two phillips screws at the upper left and lower right of the right crankcase half.



Right crankcase half (1) and securing screws (2) (XR75)

5. Split the cases by tapping around the mating surface with a plastic mallet. The crankshaft and gear clusters will remain in the left crankcase half.

6. Detach the kick-starter return spring from the crankcase and pull out the kick-starter shaft assembly.

7. Remove the cam chain from the crank sprocket and take out the crankshaft. The left case may be heated slightly with a propane torch in the vicinity of the crankshaft bearing boss to facilitate removal.

Crankshaft (1), shift fork shaft (2), shift fork (3), and shift drum (4)

8. Remove the shift fork shaft and the two shift forks. Remove the shift drum.

9. Remove the main- and countershafts and their gears as a unit.

10. Refer to the inspection procedures following.

Transmission

Inspection procedures for the transmission are outlined in "Engine Rebuilding."

Kick-Starter

1. Check the splines on the kick-starter shaft and replace the shaft if they are damaged to the extent that they will not secure the kick-starter lever properly.

2. If the kick-starter gear has a plain bore, check that it is not galled or worn. If the gear has a splined bore, check that the splines are in good condition, and that the gear does not have excessive backlash on its shaft.

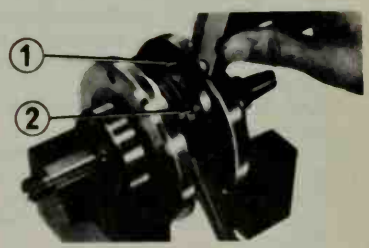
3. Check the condition of the gear teeth. On models with the ratchet-type kick-starter, the teeth on the side of the kick-starter gear are critical. If chipped or worn, the gear should be replaced.

4. Check the condition of the teeth on the ratchet gear and replace the gear if they are worn.

5. Check that the gear splines on the kick-starter shaft (where fitted) are in good condition. Check that the kick-starter shaft stopper or spring retainer and the stopper on the crankcase are not worn or chipped. If a stopper bolt is fitted, be sure that it is firmly secured in the case.

6. Check that the kick-starter shaft return spring is able to hold the kick-starter lever firmly in place. If the lever fails to return to its proper position, replace the return spring.

7. Check the retainer spring fitted to ratchet-type starters and replace it if bent or otherwise damaged.



Crankshaft

The crankshaft is a pressed-together unit. The connecting rod big end bearing is the caged-needle type. In the event of damage to the con rod, bearing or crankpin, the crankshaft must be replaced as an assembly.

1. Lubricate the big end bearing with oil, and rotate the rod slowly around the crankpin. The movement must be smooth and silent.

2. With a dial gauge, check the up-and-down (radial) movement of the con rod. Compare the reading with the specification given. If rod movement is in excess of the specifications, the big end bearing is worn and the crankshaft must be replaced.

3. With a feeler gauge, check the clearance between the con rod big end and the crankshaft flywheel. Compare the measurement with the specification given for axial clearance.

Checking big end side clearance (2) with a feeler gauge (1)

4. Place the crankshaft on a set of V-blocks, and check the crankshaft run-out with a dial gauge. Check both ends of the crank. Compare the run-out reading with the specification given for your model. If excessive, the crank must be replaced.

Crankshaft run-out will be one half of the true indicated reading of the gauge.

Crankcases

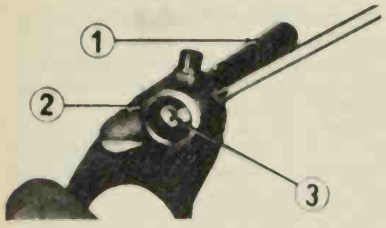
1. Check for damage to the bearing bosses, especially for stress cracks around the bearing boss.

2. Be sure that both case half mating surfaces are free of any traces of old gasket or gasket material.

3. Place each case half on a flat surface and check for warpage by probing around the mating surface with a feeler gauge. Maximum acceptable case warpage is 0.05 mm (0.002 in.). If warped, cases should be replaced.

4. Minor scratches on the mating surfaces can be removed with an oilstone, although it is not permissible to remove much metal.

5. Case halves must be scrupulously clean before assembly. Be sure that all oil passages are clear and that any dowel pins fitted between the case halves are installed.



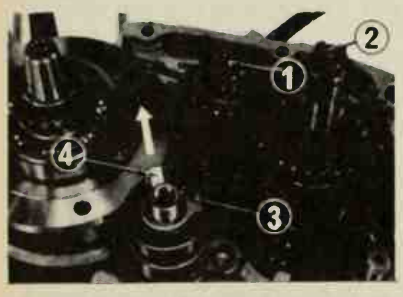
Crankcase Assembly

100–125 CC MODELS

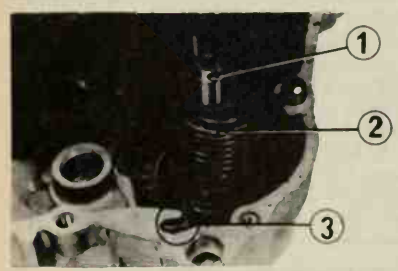
1. Assemble the shift drum mechanism if it was disassembled. The left gearshift fork is secured by a spring-loaded ball. To install, insert the spring and the ball into the shift fork, push the ball down with a thin screwdriver, and slip in the shaft.

2. Install the components into the case in the reverse of the removal procedure. Note the following points:

a. Install the crankshaft into the case by pushing it straight in until the bearing is seated. Do not strike the end of the crankshaft to install it;

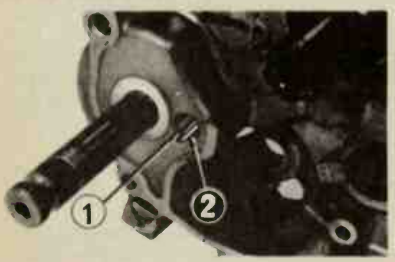


Installing the shift fork shaft (1) in the fork (2) by compressing the ball and spring (3) with a thin phillips screwdriver (100-125 cc)



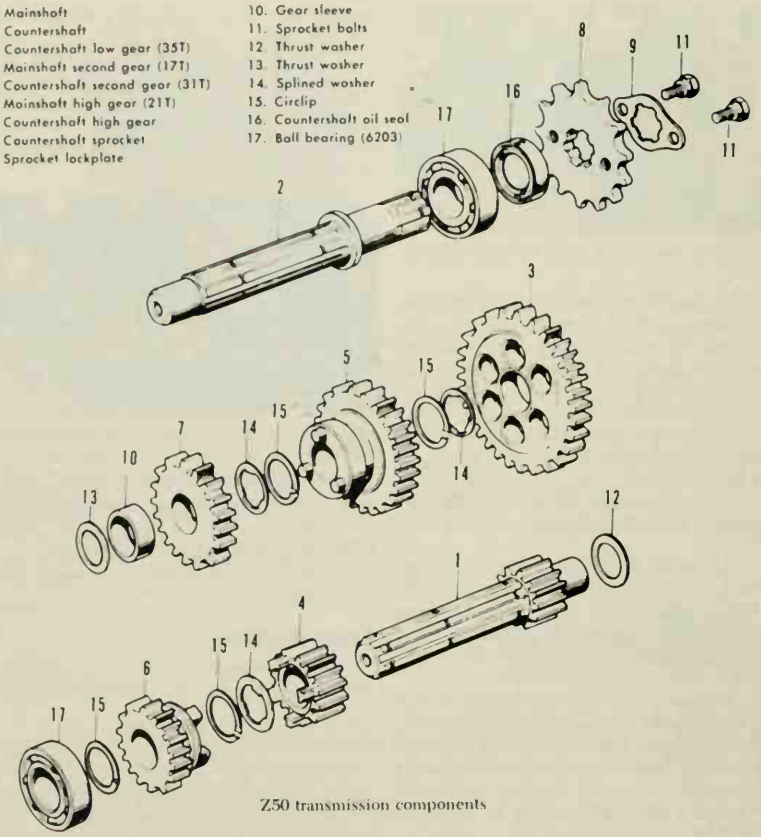
b. Install the gear clusters first, then the shift drum. Position the shift drum so that the neutral switch rotor would be parallel with the cylinder. This is equivalent to Neutral. Noting the locating marks on the shift forks, install the right, center, and left forks, in that order, engaging the cam follower pin of each fork with the proper groove in the shift drum. Then install the shift fork shaft;

c. Install the kick-starter shaft. Be sure that the return spring is seated in the crankcase. The retainer spring must protrude through the hole in the crankcase as illustrated;



d. Lubricate all bearings with motor oil;

The neutral switch rotor (4) on the shift drum (3) should be parallel with the cylinder (about 10° from vertical) when installing the shift forks (100-125 cc)



When installing the kick-starter assembly (1), be sure that the end of the return spring (2), is fitted into the cutout in the case (3)

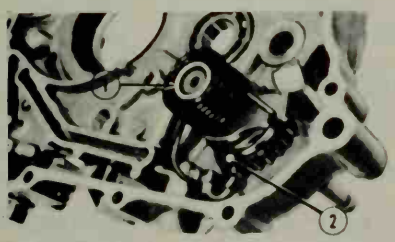
e. Fit a new gasket. Ensuring that the transmission is in Neutral, assemble the case halves. Do not force the cases together. Install the crankcase screws and tighten them in a cross pattern, to about 8 ft lbs;



NOTE: *Do not use the screws to mate the cases. This should be accomplished before they are tightened.*

f. Check for free rotation of the crankshaft and the gears, and operation of the kick-starter and shifter.

90cc MODELS

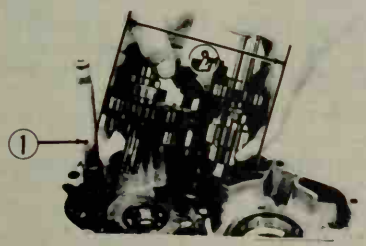
1. Assemble the shift drum mechanism if it was disassembled. Slide the forks onto the shift drum, install the pins, and fit the securing clips.

2. Assemble the shift drum assembly and the gear clusters and insert them into the left crankcase half. On newer models, the kick-starter shaft is inserted into the right crankcase half, the left half on older machines.

Kick-starter components (late models, 90 cc)

3. Install the crankshaft in the left case half, after heating the case as on removal. Do not strike the crankshaft to seat the bearing.

4. Lubricate all interior components with motor oil.



5. Be sure that the mating surface dowel pins are in place. Fit a new gasket. Mate the case halves. Do not force or strike the cases to bring them together.

6. Fit the case screws and the shift drum bolt

7. Check for smooth rotation of the crank and correct operation of the shifter mechanism.

50–70CC MODELS (EXCEPT XR75)

1. Assemble the shift drum mechanism if it was disassembled. Slide the forks onto the shift drum, install the pins, and fit the securing clips.

Installing the gear clusters (50-70 cc)

2. Assemble the shift drum assembly and the gear clusters and insert them into the left crankcase half. Insert the kick-starter assembly.

3. Install the crankshaft in the left case half, after heating the case as on removal.

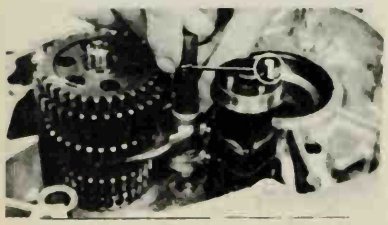
4. Lubricate all interior components with motor oil.

5. Be sure that the mating surface dowel pins are in place. Fit a new gasket. Mate the case halves. Do not force or strike the cases to bring them together.

6. Fit the case screws. Note that the case screws are of different lengths. Tighten the case screws in a cross pattern to about 8 ft lbs. Do not tighten the screws unless the cases are mated. Do not use the screws to mate the cases.

7. Hold the shift drum against the case and install the shift drum bolt.

8. Check for smooth rotation of the crank and proper operation of the shift mechanism and kick-starter.

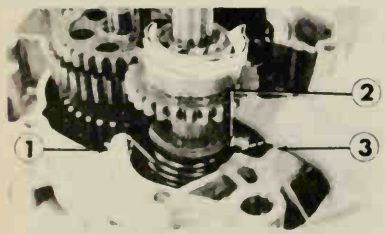


XR75

1. Install the gear clusters together in the left crankcase half.

2. Install the shift drum insuring that the neutral switch rotor on the drum points toward the neutral switch on the case.

3. Install the center gearshift fork, engaging it first with the mainshaft Third gear and then with the groove in the shift drum.



4. Install the right gearshift fork engaging it with the countershaft Second gear and the shift drum. Install the shift fork shaft. Check gear rotation.

Installing the shift fork shaft (1) (XR75)

5. Install the kick-starter shaft, engaging the end of the return spring with the crankcase lug. Install the kick-starter pedal onto the shaft, and use it to rotate the shaft until the kick-starter spring retainer can be pushed down into the recess in the case.

6. Loop the cam chain through the cutout in the left case, then install the crankshaft. The case bearing boss may be heated slightly as on removal to facilitate installation of the crank.

Rotate the shaft as shown until the spring retainer (2) can be pushed down into the recess (3). The other end of the return spring must be engaged as shown (1).

7. Lubricate all interior components with motor oil.

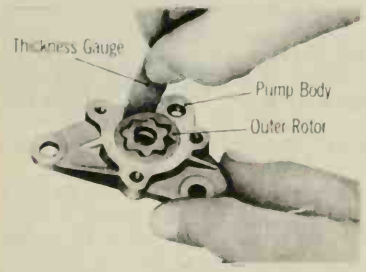
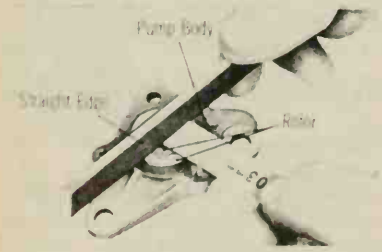
OIL PUMP SERVICE



50–90 cc Models

1. Remove the right crankcase cover and clutch assembly as described in the "Engine and Transmission" chapter.
2. Remove the three mounting screws and/or bolt from the oil pump, and remove the oil pump assembly.



Oil pump (1) and cover (2) (50-90 cc)

3. Remove the cover screws and remove the cover. Remove the inner and outer rotors, and inspect for obvious damage.
4. Install the rotors and measure the clearance between the outer rotor and the oil pump body with a feeler gauge. Replace the pump if clearance is excessive.

Measuring outer rotor-to-pump body clearance

5. Measure the rotor end-play by placing a straightedge across the cover surface with the gasket in place and measuring the clearance between the straightedge and the rotors with a feeler gauge.

Checking rotor end-play

6. Measure the clearance between the rotors with a feeler gauge. Excessive clearance will cause excessive backlash

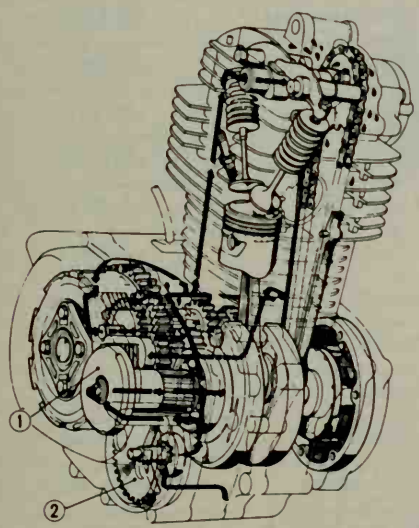
and noisy pump operation. Replace the pump if clearance is excessive.

7. Assemble the pump using a new cover gasket. The gasket must not touch the rotors. Try to turn the pump by hand, it should turn freely with little resistance.

Be sure that the driving tab of the pump is properly fitted into its slot upon installation



8. Install the pump on the engine. Be sure to line up the tab on the pump drive with the slot in the pump driveshaft.

XR75, 100–125 cc Models

1. Drain the crankcase. Remove the exhaust system. Remove the kick-starter.
2. Disconnect the clutch cable from the right-side cover. Remove the skid plate and step bar (if fitted).
3. Remove the right crankcase cover.
4. Remove the oil filter rotor cover.
5. Using the special wrench, remove the rotor nut.

NOTE: *To stop the crankshaft from turning, engage the transmission and apply the rear brake or use a block of wood jammed between the primary gear and the clutch gear.*

6. Remove the oil pump gear cover.

7. Remove the oil pump drive gear and shaft. Note the thrust washer on the end of the shaft.
8. Remove the two pump mounting bolts and remove the oil pump.
9. Remove the two screws from the cover on the back of the oil pump, and remove the cover.
10. Remove the two rotors and inspect

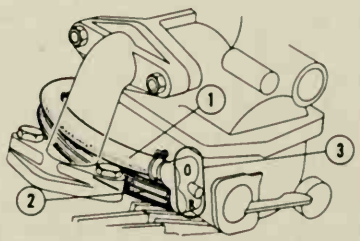
FUEL SYSTEM



CARBURETOR

The following section deals with the removal and installation, and disassembly and assembly of the carburetor. Inspection and service is outlined under "Carburetor" in "General Information."

Removal and Installation

Procedures will vary depending on model.

1. Unscrew the carburetor cap and pull the throttle slide assembly out of the carburetor. If the slide assembly is to be disassembled, see the procedure below. If not, place a small plastic bag around the assembly to keep out dirt, and place it out of the way. Note that mishandling the assembly may necessitiate replacement of the slide or needle.

The main (1) and reserve (2) fuel lines must be correctly connected

2. On models which have the fuel petcock located on the carburetor float bowl (CT and ST models for example), pinch off the fuel main and reserve lines with a small C-clamp or the like; move the fuel line clips back up the line and disconnect the main and reserve lines from the carburetor. Be sure to note where each line is connected before disconnecting them.

Alternately, loosen the carburetor drain knob, turn the petcock to "reserve" and allow the contents of the tank to drain into a container by way of the drain line.

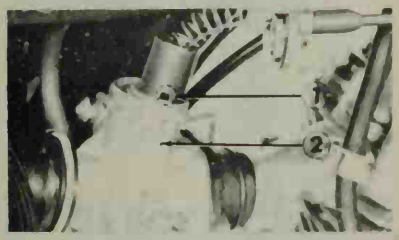
3. On other models, check that the fuel is shut off, and disconnect the fuel line from the carburetor.

4. Remove the float bowl drain plug (if fitted) and drain off any gas in the float bowl. Disconnect any overflow or breather tubes.

5. Loosen the carburetor or manifold mounting nuts a bit at a time until loose, then remove them.

6. Loosen the air cleaner hose clamp or band. Remove the carburetor.

7. Installation is the reverse of the above, but the following points should be noted:



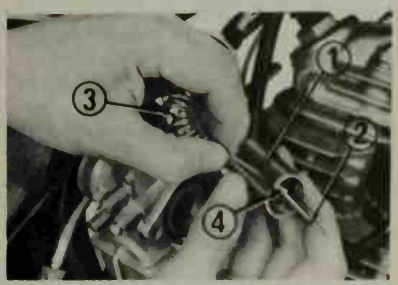
a. Be sure that the carburetor mounting flange O-ring is installed in its groove before fitting the carburetor;

b. When tightening the carburetor or manifold flange nuts, do so evenly to prevent warpage;

c. On models with a carburetor mounted petcock, note that the petcock

pipes are marked. Be sure to connect the correct line to the pipes;

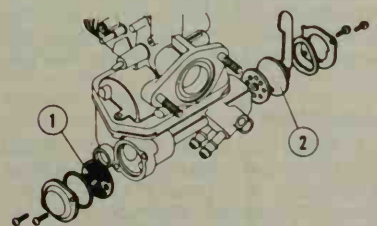
d. Lubricate the throttle slide if desired with a molybdenum or graphite lubricant. Insert it into the carburetor with the slide cutaway facing away from the engine. Be sure that the slot in the slide is engaged with the tab in the carburetor body;



When fitting the slide, note that the slot in the slide (1) is engaged with the tab in the carb body

e. Be sure that the slide goes in easily, and especially that the needle enters the needle jet. Do not push or force the slide into place. If resistance is noted, it is probable that the needle is cocked to one side and is not entering the jet;

f. Tighten the carburetor cap and check throttle operation. The slide must move freely up and down.



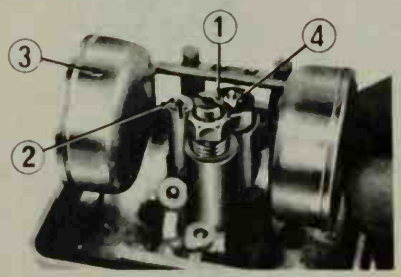
Disassembly

1. If disassembly of the throttle slide components is desired, compress the return spring against the carburetor cap, disengage the cable from the slide, take out the spring clip, needle, and clip.

To disassemble the throttle slide, compress the return spring (3) and slip the cable end (4) out of the slide

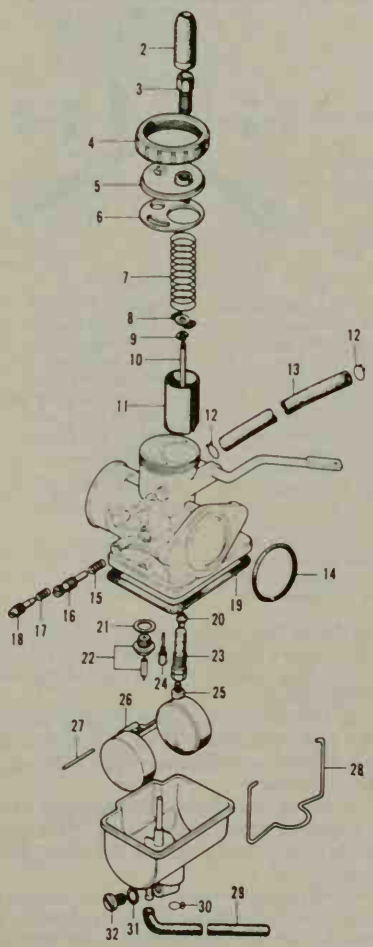
2. Remove the float bowl petcock filter (if so equipped) by removing the filter plate, O-ring, and filter screen.

Carburetor-mounted petcock components: (1), filter screen; (2), lever



3. Remove the float bowl screws or flip up the retainer and separate the float bowl from the carburetor body. Do so carefully, to avoid damage to the floats. Remove and discard the float bowl gasket.

NOTE: *If the bowl is stuck, tap carefully with a plastic mallet to break the seal.*



4. Push out the float pivot pin with a small dowel, and take out the floats. Remove the float needle from its seat. Unscrew the seat itself.

5. Unscrew the main jet.

6. Several types of needle jet (located directly above the main jet) are fitted. Some models have only the jet itself, while others have a jet holder or nozzle with the needle jet located above it. Unscrew the needle jet or jet holder if a means is provided (such as a hex head), or simply push the jet holder and/or jet out of the carburetor body with a wooden dowel.

Main jet (1), pilot jet (2), floats (3), float needle (4)

Carburetor assembly (100-125 cc)

7. Unscrew and remove the pilot jet.

8. Remove the pilot air and throttle stop screws and springs, and the drain knob (if fitted).

Assembly

Assembly is basically the reverse of the above, but note the following points:

1. Float bowl gaskets and manifold and needle jet O-rings (where fitted) should always be replaced with new ones. Other O-rings or fiber gaskets should be carefully inspected and replaced if less than perfect in condition. Check O-rings for tears or cracks, fiber gaskets for crushed condition.

2. Exercise care when installing jets. Install the needle jet, holder if fitted, main jet, pilot jet, and float needle seat.

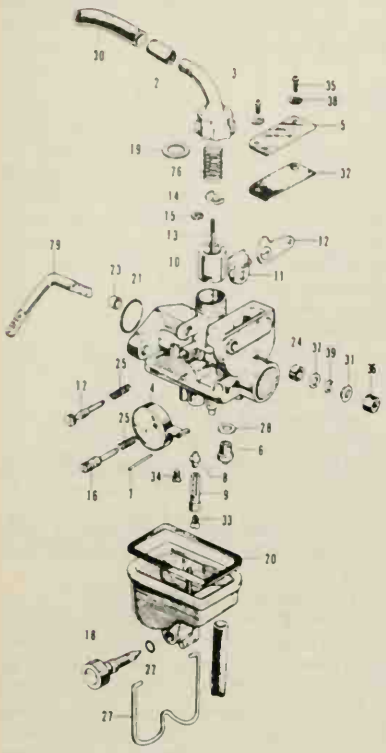
Some models have an O-ring on the needle jet which must be in place.

CAUTION: *Do not overtighten the jets as they are made of soft brass which is easily damaged.*

3. Install the float needle into its seat. Hold the floats in place and install the pivot pin.

4. Assemble the throttle slide.

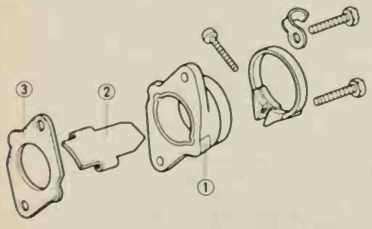
5. Install the pilot air screw, turning it in until lightly seated, then backing it out the proper number of turns as listed in the chart at the end of this chapter.



6. After completing assembly, install the carburetor on its manifold. If the carburetor bolts to the manifold, make sure that the bolts or nuts are tightened evenly, but not overtightened.

7. Check for fuel or air leaks; make final adjustments to the throttle stop and pilot air screws.

Atomizer Plate



An atomizer plate has been fitted to the intake manifold on some 1976 models. The plate needs no service or maintenance, but if removed, it must be installed in the correct way. Refer to the illustration of the unit.

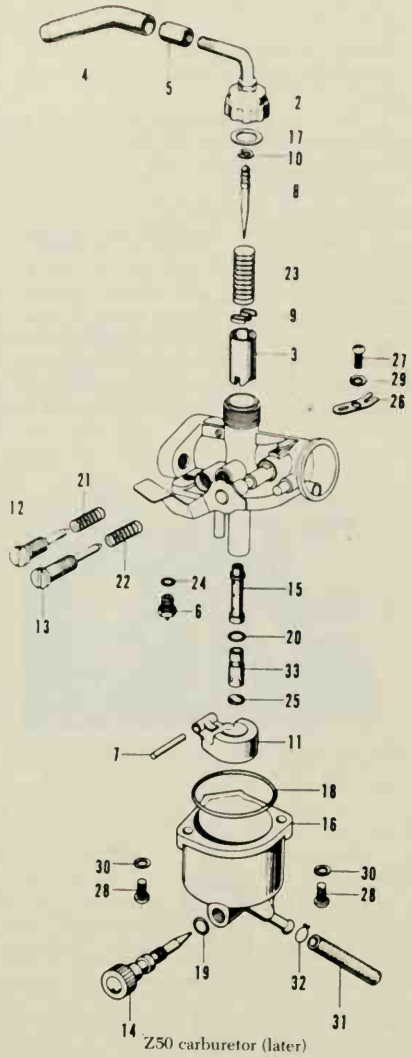
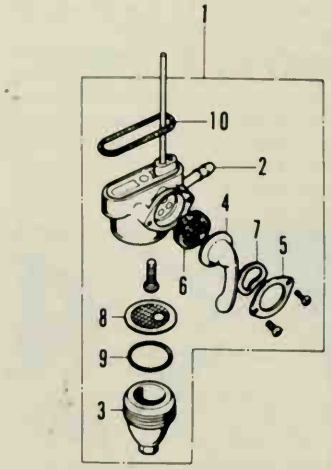
FUEL PETCOCK AND LINES



Cleaning

1. On models with the petcock located on the carburetor float bowl, turn the fuel off, remove the filter screen cover plate (two screws), then remove the O-ring and filter screen.

2. On models with the petcock on the gas tank, unscrew and remove the sediment bowl, and take out the O-ring and filter screen.



3. Some models are not equipped with a sediment bowl, and removal of the petcock is required to clean the filter. See below.

4. Clean the metal parts in solvent. Check that the filter screen is not punctured, and that the O-ring is not torn or otherwise damaged.

4. Petcock lever
5. Lever plate
6. Gasket
7. Spring
8. Filter
9. O-ring for sediment bowl
10. O-ring for petcock body

5. Run a little gasoline through the petcock to flush out any dirt. Catch the gas in a suitable container. Turning the petcock to "Reserve" for a few seconds should remove the better part of any water or dirt in the bottom of the gas tank.

6. Check petcock operation in all operations. There must be no fuel flow when the petcock lever is turned to the "stop" position.

7. Replace the filter screen, O-ring, and sediment bowl or cover plate in that order. Check for leaks before operating the motorcycle.

Disassembly

At somewhat more extended intervals, the petcock should be removed from the gas tank or carburetor and cleaned.

1. Drain the gas tank completely. Disconnect the fuel line(s) from the petcock.

2. On petcocks which have sediment bowls, remove the bowl, O-ring and filter screen.

3. Remove the phillips screws beneath the filter screen and remove the petcock from the gas tank.

4. On tank-mounted petcocks without a sediment bowl, unscrew the nut which secures the petcock to the tank and remove the petcock. Remove the filter screen and rubber gasket.

5. Remove the two screws from the fuel lever setting plate, and remove the setting plate, lever spring, lever, and gasket.

Inspection

1. Clean all metal parts in solvent and blow dry. Clean the filter screens thoroughly, or replace if there is evidence of punctures or damage.

2. Inspect the O-rings for damage and replace if any is noted, or if leakage was evident in the petcock. Check any gaskets for crushed or cracked condition. Inspect the lever spring for cracks or fatigue.

3. Inspect the fuel lines for cracks or

abrasion damage. Replace if any sort of fault is noted.

Assembly

1. Install the fuel valve gasket, lever, spring, and setting plate. Secure with the two screws.
2. Be sure that the petcock O-ring (if fitted) is properly seated, or that the gasket is in place.
3. Install the petcock on the tank. Fit the sediment bowl filter, O-ring, and bowl if applicable. Check for leaks.
4. Be sure that all fuel lines are firmly secured at their connections and that the safety circlips are in place.

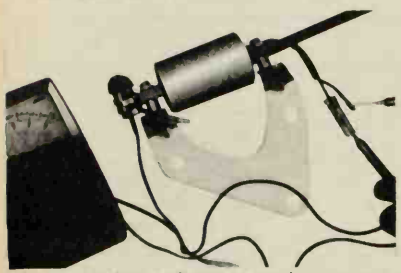
ELECTRICAL SYSTEMS

IGNITION CIRCUIT

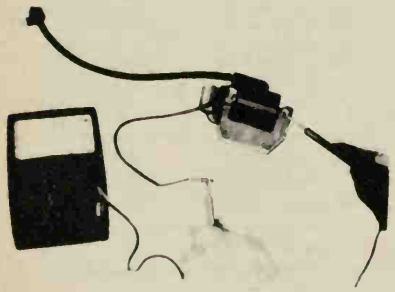
Hard starting or misfiring are often caused by ignition system troubles, but since electrical malfunctions are often trickier to pin down than carburetor faults, it is wise to ensure that systems other than the ignition are in serviceable condition before beginning any work.



1. In the event of hard starting, misfiring, or cutting out, first check that all electrical connections are clean and tight. If the machine will not start at all, check the fuse (near the battery) first.
2. On battery ignition machines, check the charge of the battery and recharge or replace it as necessary. Be sure that the battery terminals are clean and the connections secured tightly.
3. Check the ignition and kill switches for continuity.
4. Check the ignition timing for accuracy.
5. Remove the spark plug, clean it thoroughly, or replace it with a new one; gap the plug to 0.6–0.7 mm (0.024–0.028 in.). Connect it to its cap, and ground it against the cylinder head. Kick the engine over briskly. The spark produced should be thick and blue.
6. If there is no spark, or if the spark is weak and yellow, repeat the test using a piece of metal, such as a nail, inserted into the spark plug cap and held about ⅛ in. away from the cylinder. If the spark is healthy, the problem was the spark plug; if not, check the condition of the points. Inspect, clean, and gap the points or replace them if they are badly pitted or worn. If excessive arcing or sparking at the points is noted while the machine is running, the problem may be the condenser. A defective condenser will also cause new points to wear out quickly.
new points to wear out quickly.
7. If the problem is not in the points or the spark plug, the spark plug cap should be checked. Noise suppressor caps are fitted, which are designed to eliminate radio interference and provide a hotter spark by means of a resistor in the cap. Sometimes the resistor breaks down, and the cap then becomes an open circuit. Remove the cap from the spark

plug lead, and ground the end of the lead against the cylinder head. If a fat, blue spark is produced when the engine is kicked over, the problem was the cap. Replace it with a new one.

8. If the cap checks out okay, carefully inspect the cable itself. Check for dirt or grease, cuts or cracks in the insulation, moisture, etc. If the lead is damaged, it must be replaced. This also involves replacing the coil.



9. If the trouble has not been pinpointed, the ignition coil windings should be checked for continuity, using an ohmmeter.

a. On battery ignition machines, disconnect the two low-tension coil leads and check for continuity between them. This is a check of the primary winding. If there is no continuity, replace the coil;

Checking ignition coil primary winding continuity (battery ignition)

b. On magneto ignition machines, check the primary winding by checking for continuity between the coil's low-tension wire (black or black/white) and the coil mounting plate. If continuity does not exist, replace the coil;

Checking primary winding continuity (magneto ignition)

c. On battery ignition machines, check for continuity across the coil's blue low-tension lead and the high-tension (spark plug) lead. Resistance may be very high (5–10,000 ohms), but continuity must exist. This checks the secondary winding;

d. On magneto ignition machines, check for continuity across the high-tension lead and the coil mounting bracket. If there is no continuity, replace the coil.

Even if continuity is present in the coil windings, it is possible that the coil is still defective. Replacing the coil temporarily with one which is known to be serviceable is recommended.

10. The condenser can be checked. If a capacitance tester is available. Condensers should have a capacitance of approximately 0.25mf. Checking with a "megger" (high-voltage ohmmeter) should yield a resistance of 10M ohms at 1,000v.

On battery ignition machines, the checks above cover all ignition circuit components and the trouble should be evident. On magneto ignition bikes, the magneto itself must be checked if the cause of the problem has not yet been determined.

Assuming that all other ignition circuit components have been eliminated as the possible trouble spots, and the ignition and kill switches have been checked, proceed as follows:

1. Remove the left crankcase sidecover and the magneto rotor. A special puller must be used to remove the rotor.

2. Check the rotor for any score marks which would indicate that the rotor is contacting the core ends. If so, the condition must be remedied. If this has occurred, check for any play in the crankshaft which would indicate a bad crankshaft bearing. Other reasons may be improper mounting of the coil cores or rotor, worn crankshaft taper, or rotor taper surface. If the taper is damaged, the rotor should be replaced. Also inspect the rotor for any cracks or fractures. If present, replace.

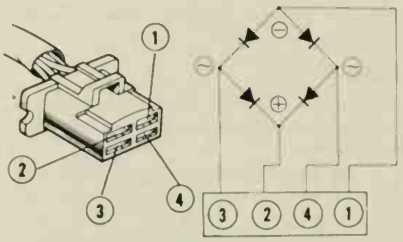
3. Check for continuity between the black or black/white wire and ground. If continuity does not exist, the primary exciting coil is either broken internally, or is poorly grounded.

NOTE: *If this test is made with the coils still on the engine, be sure that the points are open or held open with a bit of thick paper.*

4. Check the resistance between the coil core and the mounting plate or crankcase cover. The coil core should be well grounded (no resistance).

CHARGING CIRCUIT

Battery Ignition Models



1. In the event that the battery overcharges, check the condition of the battery itself. A shorted or defective battery is the most likely cause.

2. If the battery discharges quickly, or fails to hold a charge, check the battery, rectifier, and alternator.

RECTIFIER

An ohmeter or a continuity tester is used to check the rectifier. Do not use a megger.

1. Disconnect the rectifier leads at the plastic connector. There are four leads wired to the connector. This rectifier is the full-wave type, consisting of four diodes wired as shown in the illustration. To check the rectifier, you will be checking each diode in turn to ensure that current will flow through each in one direction only. Current flow in both directions, or no current flow in either direction through a diode indicates that it is defective.

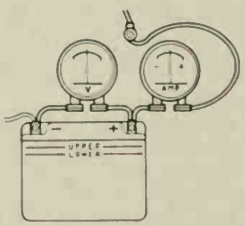
Full-wave rectifier leads

1. Green
2. Red/White
3. Yellow
4. Pink

2. Connect the negative lead of the tester to the green wire, and the positive lead to the yellow, red/white, and pink wires in turn.

In each case, note whether or not there is continuity.

NOTE: *On an ohmmeter, "continuity" will be indicated by a resistance of 5–40 ohms. "No continuity" by a resistance of 100 or more ohms.*



3. Now reverse the tester connections, connecting the positive tester lead to the green wire, and the negative to each of the others in turn.

In every case, the reaction of the tester must be the opposite of the first test: i.e., if the first test showed continuity between two leads, reversing the tester connections must show no continuity.

Continuity in both directions, or lack of continuity in both directions for any given pair of wires is indicative of a defective rectifier.

ALTERNATOR

1. A dynamic test may be carried out if a voltmeter and ammeter are available. The battery must be fully charged. Hook up the voltmeter across the battery terminals, and the ammeter to the positive terminal of the battery and to the red/white lead, as shown.

Voltmeter and ammeter connections to check alternator output

2. Start the engine and note the voltmeter and ammeter readings at the given rpm and compare them to those given in the "Alternator Output" chart for your machine. If the readings are not within the proper specifications, the stator coil should be removed from the machine and checked for continuity as outlined below.

3. Check for continuity between all three stator leads. Continuity must exist, or the stator assembly has a broken wire and it must be replaced.

4. Check for continuity between the yellow lead and the stator core. If continuity exists, there is a short, and the stator must be replaced.

Alternator Output

Off	6.8v, 1000 rpm	7.8v/1.3a

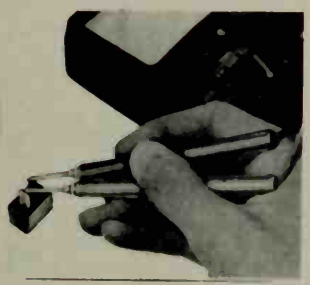
Off	6.8v, 1000 rpm	7.9v/1.7a
Low beam	6.8v, 2000 rpm	7.8v/1.3a



Magneto/Alternator Models

1. Rectifiers are fitted to models which have batteries. In the event that the battery overcharges, it is probable that the battery itself is faulty.

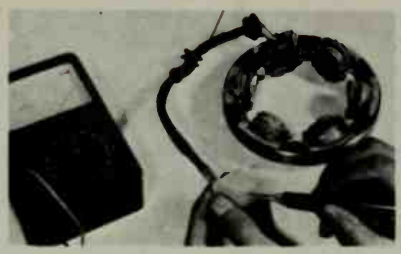
2. If the battery fails to hold a charge or discharges quickly, check the battery itself, then the rectifier and magneto lighting coil.

RECTIFIER

1. The rectifier is a simple half-wave unit which has two leads (red/white and green). To check the rectifier, disconnect these leads, and connect a test light or ohmmeter across the rectifier terminals. Note whether or not continuity exists. Now reverse the leads and note whether or not there is continuity.

Checking the half-wave rectifier

2. There must be continuity in one direction only. If there is continuity in both directions or neither direction, the rectifier is defective. If an ohmmeter is used, resistance should be 5–40 ohms in the forward direction (continuity) and about 600 ohms for the reverse.



ALTERNATOR

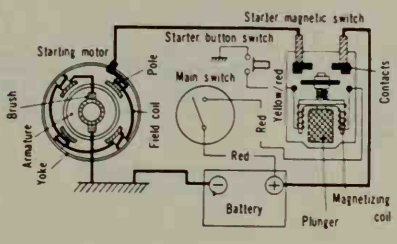
1. To check the lighting coil, use an ohmmeter or continuity light.

2. Disconnect the alternator wiring at the plastic connector. Check for continuity between the green lead and ground on the engine case. Check for continuity between the yellow lead and ground. Check for continuity between the green and the yellow leads. Continuity must exist in all three cases or the lighting coil must be replaced.

3. If lights are dim on models which have no battery, suspect the magneto/alternator coil. Check for burned wiring, scored coil core ends, etc. Make continuity checks as in Step 2.

If the coil seems satisfactory, the rotor magnets may have become weakened. Replace the rotor if this has happened.

Checking for continuity between alternator leads



STARTING SYSTEM

The starting system consists of the starter motor and clutch, the solenoid, and the handlebar-mounted starter switch. When the button is pressed, the electrical circuit to the solenoid is closed and the solenoid is activated, sending the battery current directly to the starter motor. The starting system is quite reliable and it is unlikely that you will experience any major problems.

Testing

1. If the starter will not operate, switch on the headlight and observe its intensity. If it is dim when the starter is not being operated, check the battery connections and recharge the battery. If the headlight doesn't light, check the fuse, and the battery connections, and check the electrical continuity of the wire between the ignition switch and the battery.

2. If the headlight is bright, press the starter button momentarily and watch the light. If it remains bright, touch a screwdriver blade between the two starter solenoid terminals. If the starter operates, connect a test light between the small yellow/red wire on the solenoid and ground. If the test light comes on as the button is pushed, the solenoid is faulty. If it does not light, look for defective wiring between the starter button and the ignition switch, or simply a burned out starter button switch. If the starter does not operate and the headlight dims as the main solenoid terminals are bridged, the starter motor is faulty. If the headlight does not dim, look for a bad connection at the starter.

Electric starter wiring diagram

3. If the starter motor operates freely, but will not turn the engine over, the starter clutch is not operating (a rare occurrence). To remove the clutch it will be necessary to first take off the left-side crankcase cover and remove the alternator rotor. If the overrunning clutch is defective and the starter keeps spinning after the engine starts, it must be repaired immediately to prevent serious damage to the starter assembly.

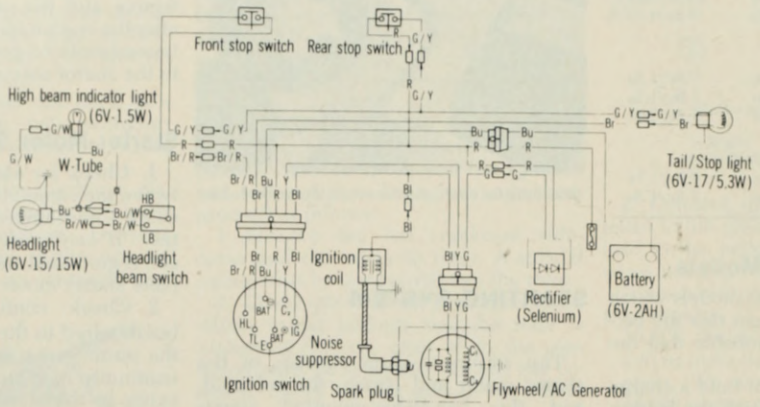
Starter Motor Service

1. Check for electrical continuity between the commutator and armature core using a multimeter or test light and battery. If continuity exists, the armature coil is grounded and the armature or complete starter motor should be replaced.

2. Check continuity between the brush wired to the stator (field) coil and the starter motor cable terminal. Lack of continuity indicates that an open circuit exists in the stator coil and the starter motor unit should be replaced.

3. Examine the carbon brushes for damage to the contact surfaces and measure their length. Replace the brushes as a set if they are damaged in any way or if they measure less than 0.3 in. (7.5 mm).

4. Brush spring tension should be determined with a small spring scale. Replace the springs if they exert less than 0.8 lbs of tension.



5. Polish the commutator with fine emery cloth and blow it off thoroughly before installing it. Check the following components for excessive wear and damage: clutch spring and rollers; bearings; bushings; oil seal; reduction gears; and the sprockets. Replace all parts as necessary if worn or damaged. When reassembling the starter clutch, apply a thin coat of silicone grease to the rollers.

Starter Solenoid Service

The solenoid is an electromagnetic switch which closes and completes the circuit between the starter and the battery when activated by the starter button. The solenoid is a necessary addition to the starting circuit because the starter button switch is not capable of handling the amperage load required to operate the starter, and because mounting a heavy-duty switch on the handlebar, with the large cable needed to handle the load, is impractical.

If the solenoid does not work, check the continuity of the primary coil by connecting a multimeter or test light and battery to the two small solenoid leads. Lack of continuity indicates an open circuit and the solenoid must be replaced. If the primary coil winding is continuous, disassemble the solenoid and clean the contact points with emery paper or a small file. The points, after long use, have a tendency to become pitted or burned due to the large current passing across them. Be sure to disconnect the battery before disconnecting the cables from the solenoid when it is to be removed. Replace the solenoid if cleaning the points fails to repair it.

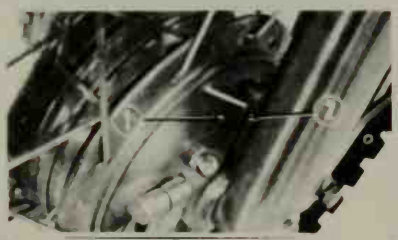
Removal and Installation

FRONT WHEEL

1. Support the front wheel off the ground by placing a crate or another suitable object beneath the engine.



To remove the front wheel disconnect the brake cable (1), speedometer cable (2), and remove the cotter pin (3), and the axle nut (4)

2. Disconnect the front brake cable (drum brakes) and the speedometer cable at the front wheel.

3. Remove the front axle nut and pull out the axle. The wheel is now free to be removed.

4. Remove the front brake assembly (drum brakes) by pulling the front brake plate from the hub.

5. Installation is in the reverse order of removal. Be sure to locate the tab on the left fork leg into the slot in the brake plate.

When installing the front wheel, the tab (2) must be fitted into the slot (1)

REAR WHEEL

1. Place the motorcycle on its center stand, or find some way to block the rear wheel up so that it can spin freely.

2. Remove the cotter pin, securing nut, lockwasher, and flat washer from the brake anchor at the brake plate.

3. Remove the cotter pin and axle nut from the left-side of the axle.

4. Remove the rear brake adjusting nut from the end of the brake cable and disconnect the cable from the brake lever.

5. Remove the masterlink from the drive chain. Place the masterlink on the end of the chain for safekeeping.

6. Pull the axle out from the right-side and remove the wheel assembly from the swing arm.

NOTE: *Place the wheel spacers on the axle in the order that they are removed, and screw the axle nut on the axle for safekeeping.*

7. To install the wheel:

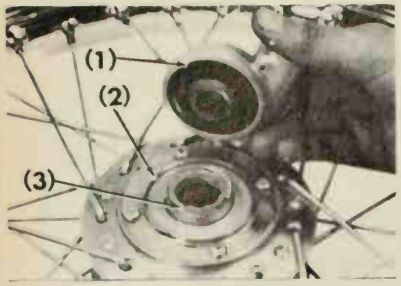
Hold the wheel in place and slip the axle in place from the right-side. Be sure that the spacers are in their correct locations. Place both ends of the chain on the rear sprocket and install the masterlink with the open end of the spring clip facing opposite the direction of rotation.

8. Engage the brake anchor with the brake plate and secure with the flat washer, lockwasher, and the nut. Install a new cotter pin in the brake anchor bolt.

9. Turn the axle nut on finger-tight. Adjust the drive chain slack; the slack, measured midway between the sprockets, should be about ¾ in.

10. Slip the brake cable through the fitting in the brake lever and install the adjusting nut. Adjust the cable so that the brake pedal has 1 in. free-play before the brake shoes contact the drum.

11. Tighten the axle nut to the proper torque, which can be found in the "Chassis Torque Specifications" chart at the end of this section. Then back the nut off until a slot in the axle nut is lined up with a hole in the axle. Secure the axle nut in place with a new cotter pin.



Wheel Disassembly

FRONT WHEEL

Disc Brake

1. Remove the front wheel from the motorcycle as described previously.

CAUTION: *Do not operate the brake lever when the front wheel is removed. To do so will advance the ratchet adjuster to a point where the disc will not fit between the pads when the wheel is installed. If this should happen, the caliper will have to be disassembled and the adjusting screw in the brake arm loosened. Refer to the "Front Disc Brake" following.*

Speedometer drive housing (1), retainer cover (2), and retainer (3)

2. Remove the speedometer drive housing from the right-side of the hub.

3. Remove the side collar from the left-side of the hub.

4. Bend back the tabs on the disc nut lockplates and remove the the disc nuts, lockplates, and the disc.

5. Remove the four phillips head screws from the retainer cover on the right-side of the hub. Remove the retainer cover and the retainer.

6. Unscrew the wheel bearing retainer using the factory tool No. 07910-3230100. If the factory tool is not available use a blunt punch and hammer. Take care not to distort the retainer or damage the threads in the hub. Replace the oil seal in the retainer if the lips are damaged.

7. To remove the wheel bearings use a blunt punch and hammer. Remove the bearing in the left-side of the hub first. Reach through the center of the hub and tap the inside of the bearing evenly around its circumference to remove it. Be sure that the bearing does not become cocked to one side on removal. After the first bearing has been removed, remove the spacer tube from the center of the hub. Remove the second bearing using a block of wood large enough to cover the entire bearing. If the bearings resist removal, gently heat the bearing bosses in the hub with a propane torch and then try to tap them out.

Drum Brake

1. Remove the front wheel from the motorcycle as previously described.

2. Remove the brake plate. Remove the cotter pin and washer from the upper brake pivot (if fitted). Spread the brake shoes by hand until they will clear the brake cam, remove the shoes complete with the brake springs from the plate.

3. Remove the pinch-bolt from the brake lever and remove the lever, return spring, flat washer, and dust seal. Push the brake cam out of the brake plate.

4. Remove the wheel spacer from the right-side of the hub. Remove the oil seals from the right-side of the hub and the inside of the brake plate. These seals can be pried out with a hooked tool as new seals should always be used on reassembly. However take care not to score the hub surface.

5. Using a propane torch, gently heat the area around one of the bearings. Turn the wheel assembly over, placing it on a bench so that the heated side faces down.

6. With a suitable drift and hammer, tap out the bearing. The spacer tube will also come out after the bearing is removed.

7. Turn the wheel over, and heat the hub in the vicinity of the other bearing as was done previously. Tap this bearing out in the same manner.

REAR WHEEL

1. Remove the rear wheel from the motorcycle as previously described.

2. Remove the brake plate. Remove the pinch-bolt from the brake lever and remove the brake lever, flat washer, and the dust seal from the brake plate.

3. Remove the cotter pin and washer from the upper brake pivot if fitted. Spread the brake shoes by hand and remove them complete with their springs from the plate.

4. Push the brake cam out of the brake plate.

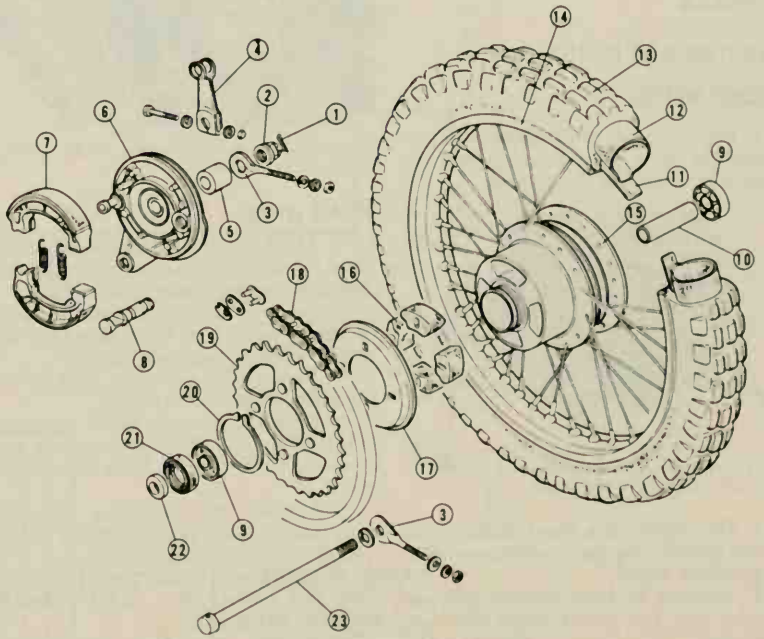
Removing the sprocket circlip

5. To service the wheel bearings the rear sprocket will have to be removed. On most models the rear sprocket is secured to the hub with a large circlip. If the sprocket has nuts on it these should be loosened before tapping the sprocket from the hub. On models with a sprocket hub, the sprocket bearing is removed in the same manner as a wheel bearing. On most models an oil seal is fitted to the hub on the outside of the left wheel bearing; this seal should be pried out with a hooked tool and a new one installed upon assembly. If a bearing retainer is fitted, unscrew it with a blunt punch and hammer. Be careful not to damage the threads in the hub.

6. Using a propane torch gently heat the hub in the area around one of the bearings. Place the wheel on a bench so that the heated side is facing down.

7. With a suitable drift reach through the center of the hub and tap out the wheel bearing, be careful not to score the hub surface. The spacer tube will also come out when the bearing is removed.

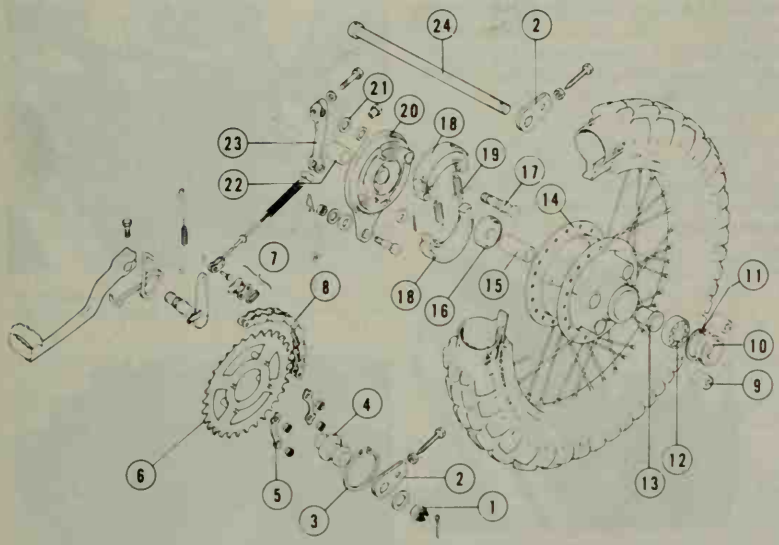
8. Turn the wheel over and heat the hub in the vicinity of the other bearing as was done previously. Tap this bearing out in the same manner.



Inspection

ALL MODELS

Brakes



1. Clean all parts thoroughly in a suitable solvent, making a special effort to remove the dust and built-up dirt from the brake plate.

2. Inspect the shoes for wear. There should be at least 2.0 mm (0.08 in.) of lin-

ing material left (measured at the lining's thinnest point) or the shoes must be replaced.

3. Inspect the linings for scoring or grooves. These may be caused by particles of dirt which enter the drum. If badly scored, the shoes should be replaced and the drum inspected closely for the same type of damage.

Be sure that the linings are free of any oil or grease. Impregnated linings must be replaced.

4. If the linings are in usable condition, rough up the surface with coarse sandpaper. Then, clean the linings with alcohol, or lacquer thinner. Clean the brake drum with the same solvent.

5. Check that the brake lever pinch-bolt is not bent. Replace it if this has occurred. Replace the brake lever if the splines are worn or broken.

6. Inspect the splines on the brake cam. These should be in good condition. The cam must rotate freely in the brake plate passage. If it does not do so, use a fine grade of sandpaper on both the cam and the surface of the passage.

7. Check the condition of the brake springs. Replace them if weakened, rusted, or deformed.

8. Check the brake plate for cracks or fractures.

Brake Drums

1. Upon disassembly of the hub, inspect the brake drum surface for condition. The drums must be clean and free of score marks or rust.

2. Rust can be removed from the drum surface with sandpaper. Polish the surface until it is shiny, then clean it thoroughly.

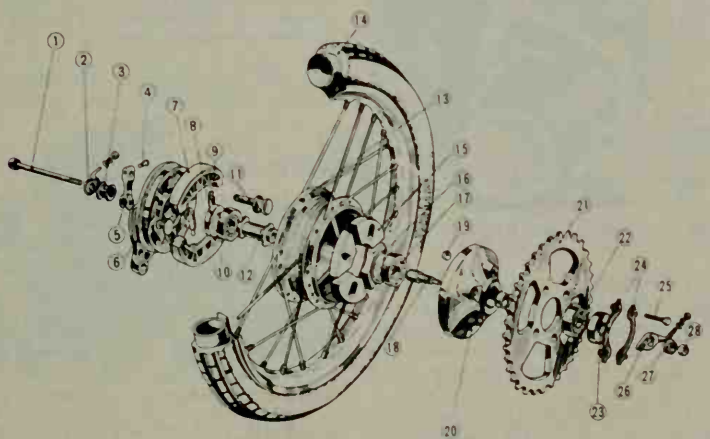
3. Alcohol or lacquer thinner can be used to remove dirt or deposits from the drum.

4. The drum should be checked for concentricity. An out-of-round condition is usually noticeable as an on-off-on feeling when the brake is applied while riding. With the wheel assembly mounted on the machine, spin the wheel while applying the brake very lightly. The rubbing noise of the brake against the drum should be heard for the entire revolution of the wheel.

5. An out-of-round condition and most scoring can be removed by having the drum turned on a lathe. This operation should be entrusted to a qualified specialist with the proper equipment. Usually, the tire and wheel bearings will have to be removed so that the wheel can be chucked in the lathe. If the rim needs to be trued, have this done before any work on the drum is performed, as the action of the spokes while truing the rim may further aggravate the drum warpage.

Cushion Hub

When the sprocket and the drive flange are removed, check the condition of the rubber dampers in the hub. Replace them if they are worn, cracked, or hardened. The dampers must not allow the drive flange to move more than ½ in. in the hub. This reading is taken by placing the flange in the hub and noting the total movement of the rim of the flange relative to the rim of the hub in the plane of wheel rotation. If movement exceeds ½ in., the dampers should be replaced.



Wheel Bearings

1. Clean the bearings, and spacer tube in a suitable solvent, removing all of the old grease. Clean out the hub as well.

2. Check the bearing bosses in the hub for scuffs, cracks, or distortion. If they are in any way damaged, the hub must be replaced.

3. Check the condition of the spacer tube, and replace if damaged.

4. Bearing condition is very important. Check the balls themselves for pitting, wear, or rust.

5. Apply a few drops of light oil to the bearing and spin it. The bearing must rotate smoothly and freely. Any roughness or binding in rotation will necessitate new bearings.

6. Place the bearing on a flat surface. Place your fingers on the outer bearing race to hold it steady. Attempt to move the inner race back and forth. In a good bearing, the race will spin, but not move in any other direction. If it does, the bearing must be replaced.

7. Note that the bearings must be replaced in pairs.

Wheel Assembly

ALL MODELS

Assembly is in the reverse order of disassembly; however, note the following points:

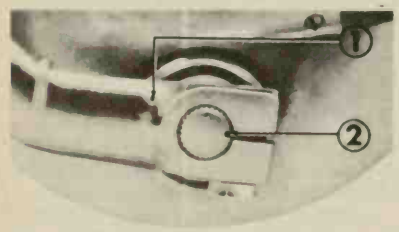
1. Obtain a good grade of wheel bearing grease to lubricate the wheel bearings.

2. Pack the wheel bearings until they are completely filled.

3. Drive one of the bearings into its seat. Put a quantity of wheel bearing grease into the hub. Install the retainer if so equipped. Install the spacer tube and drive the other bearing into its seat. The sealed surface of the bearing must face the outside of the hub, where applicable.

Bearings should be installed with a block of hardwood as a drift. Do not strike the inner race of the bearing when installing it. Tap around the outer race until the bearing is straight in the hub, then drive it straight in.

NOTE: *When a bearing retainer is fitted, the bearing with the retainer should be installed first. Then install and tighten the retainer, spacer tube, and the other bearing.*



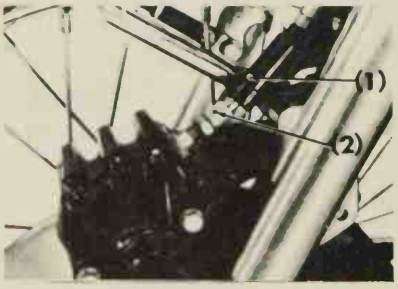
4. Replace all of the oil seals with new ones. Like the bearings, the seals should be pressed straight in.

5. Coat the surface of the brake cam with chassis grease before installing it into the brake plate.

6. Lubricate the brake shoe pivot points with chassis grease. Take care not to allow any grease to come into contact with the surface of the brake shoes or drums.

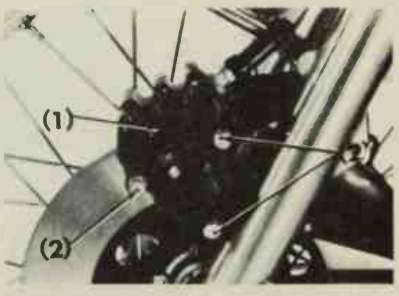
7. Line up the slots in the speedometer gear with the slots in the wheel hub.

8. Install the brake lever on the brake cam so that the punch marks on the brake lever and the brake cam are lined up.



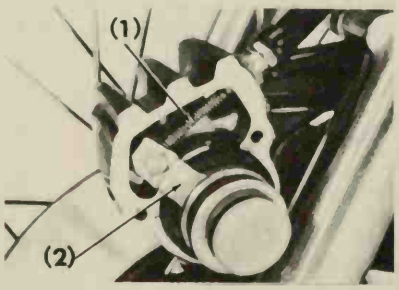
When installing the brake levers, note that the punch mark on the lever (1) must align with that on the brake cam (2)

Front Disc Brake



DISASSEMBLY

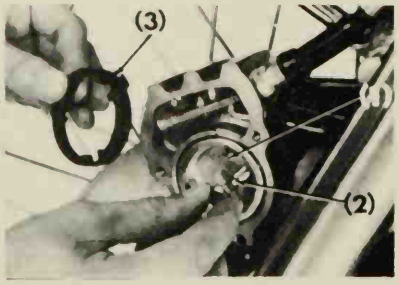
1. Slide the rubber boot on the lower part of the brake cable up on the cable to expose the brake cable adjuster in the caliper body. Loosen the locknut on the adjuster, and screw the adjuster into the caliper body as far as it will go.



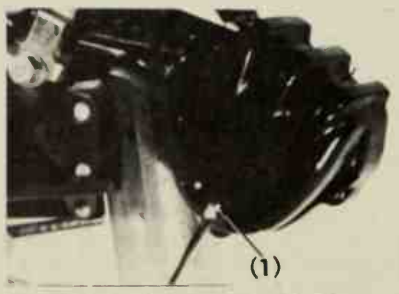
2. Remove the three 6 mm bolts from the caliper cover, and remove the cover and the ratchet fixing spring. Pull the ratchet adjuster from the brake arm. Remove the brake arm, and disconnect the brake cable.

Slide the rubber boot (1) up to expose the cable adjuster (2)

Remove the caliper cover bolts (2), and remove the cover from the caliper body (1)

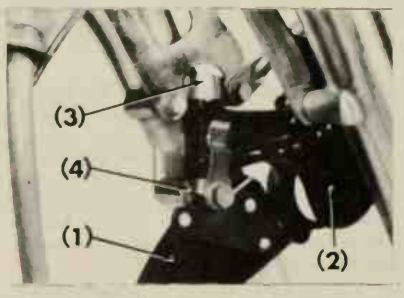


Disconnect the brake cable (1) from the brake arm (2)



CAUTION: *Cover the brake arm in a clean cloth or a plastic bag to prevent dirt from entering the inside of the mechanism. The brake arm should not be disassembled; if defective, it should be replaced.*

3. The thrust guide plate can now be removed from the caliper body. To remove the disc pads, screw one of the caliper cover bolts (6 mm) into the threaded hole in the back of pad A (the pad to the outside of the disc). Using the bolt, pull the pad out of the caliper. Remove the front wheel as described at the beginning of this section. Pad B (pad to the inside of the disc) can be removed by pushing on the lockpin on the back of the caliper body. Remove the pad from the left-side of the caliper.



4. Remove the two 6 mm and one 8 mm caliper mounting bolts from the left fork leg. Remove the disc cover, caliper body, caliper joint, and caliper pivot pin.

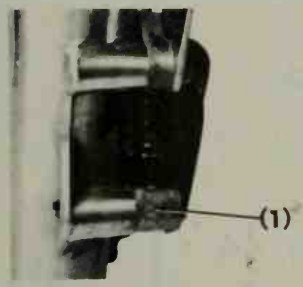
Remove the thrust guide plate (3), and screw a 6 mm screw (2), into the back of pad A (1), to pull the pad from the caliper

Push on the lockpin (1) to remove pad B from the caliper

Disc cover (1), caliper (2), caliper joint (3), and caliper pivot pin (4), can be removed after the mounting bolts are removed

INSPECTION

1. Inspect the brake pads for wear. If either pad is worn past the red wear limit line, replace both pads.



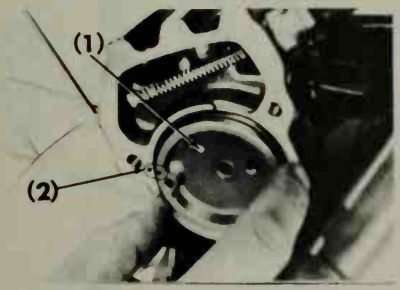
2. If the pads are scored they should be replaced. Minor score marks can be removed with sandpaper; however, take care to sand the pads flat and parallel to the disc surface.

3. Inspect the condition of all O-rings. Replace any which are damaged.

ASSEMBLY

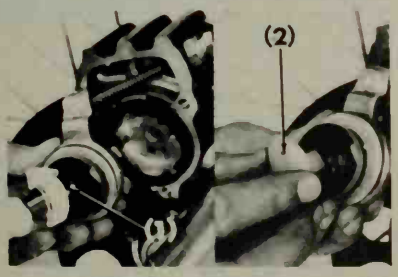
1. Install an O-ring on the caliper pivot pin and apply some chassis grease to the pin. Slip the pin through the caliper and install the remaining O-ring on the top of the pin. Slip the caliper joint over the end of the pin. Install the caliper assembly to the left fork leg, locating the disc cover to the lower (8 mm) mounting bolt. Be sure that the pivot pin is installed correctly and that the lockplate is in place on the lower mounting bolt.

2. Place a small amount of silicon grease (KS62M) on the back of pad B, and



Upon assembly be sure that the pivot pin (1), is installed correctly

install pad B into the right-side of the caliper, locating the lockpin through the hole in the back of the caliper.



3. Install the front wheel.

4. Place a new O-ring on pad A and coat the entire circumference of the pad with a thin layer of silicon grease (KS62M). Install the pad into the caliper aligning the punch marks on the pad and the caliper body as the pad is installed.

When installing pad A (1), be sure that the punch marks (2), on the pad and the caliper align

5. Install the thrust plate guide into the caliper. Connect the brake cable to the brake arm. With a small screwdriver, turn the adjusting screw in the center of the brake arm counterclockwise until resistance is felt. The adjusting screw should turn freely. Install the brake arm.

Turn the adjusting screw (1) counterclockwise until resistance is felt, then install the ratchet adjuster (2) into the brake arm

6. Install the ratchet adjuster, locating it into the slot in the adjusting screw. Install a new caliper cover gasket, the caliper cover, and ratchet fixing spring. Secure the cover with the three cover bolts.

7. Screw the adjusting bolt out of the caliper body all the way. Then screw in the adjuster until there is slack in the cable. From this position turn the adjuster out another 2 to 3 turns.

8. Operate the hand lever about 10 times. The lever should automatically adjust itself to the proper free-play ot 20–30 mm (0.8–1.2 in.) measured at the tip of the lever.

9. After adjustment is correct, slip the rubber boot over the cable adjuster. Raise the front wheel off the ground and check that the wheel spins freely.

PAD REPLACEMENT

1. The procedures for removing and installing the pads for replacement are given under "Front Disc Brake—Disassembly" and "Assembly." However, Step 4 under "Disassembly," and Step 1 under "Assembly" can be omitted.

CABLE REPLACEMENT

1. Remove the cover from the left-side of the caliper. Screw the cable adjuster into the caliper body as far as possible. Remove the brake arm with the ratchet adjuster in place and disconnect the cable from the brake arm. Screw the adjuster out of the caliper body and remove the cable from the caliper.

2. Remove the rubber boot from the hand lever, disconnect the cable from the lever, and remove the cable.

3. Connect the new cable to the hand lever and replace the rubber boot.

4. Screw the cable adjuster on the new cable all of the way into the caliper body. Connect the cable end to the brake arm and install the brake arm into the caliper body. Install the caliper cover. Turn the cable adjuster out of the caliper until there is no slack in the cable and then turn the adjuster out another 2 to 3 turns.

5. Operate the hand lever about 10 times. The lever should automatically adjust itself to the proper free-play of 20–30 mm (0.8–1.2 in.), measured at the tip of the lever.

BRAKE DISC SERVICE

The brake disc normally requires no service of any kind. However, if the disc becomes scored for any reason, it should be replaced and a new set of pads should be installed. A badly scored disc will reduce the effectiveness of the brake and shorten pad life considerably. If the front brake lever oscillates or fluctuates when the brake is applied at speed, the indication is that the brake disc is warped or bent. Check the run-out of the disc with a dial indicator and replace it if run-out exceeds 0.012 in. (0.3 mm). To replace the disc:

1. Remove the front wheel.

2. Bend back the locktabs, unscrew the six nuts, and remove the disc from the hub.

3. Mount the new disc on the hub and tighten the nuts evenly, using new locktabs to secure the nuts.

4. Examine the brake pads and replace them if they are close to the limit of wear or have worn in an unusual pattern.

FRONT FORKS

Removal

MINI-TRAIL FORK

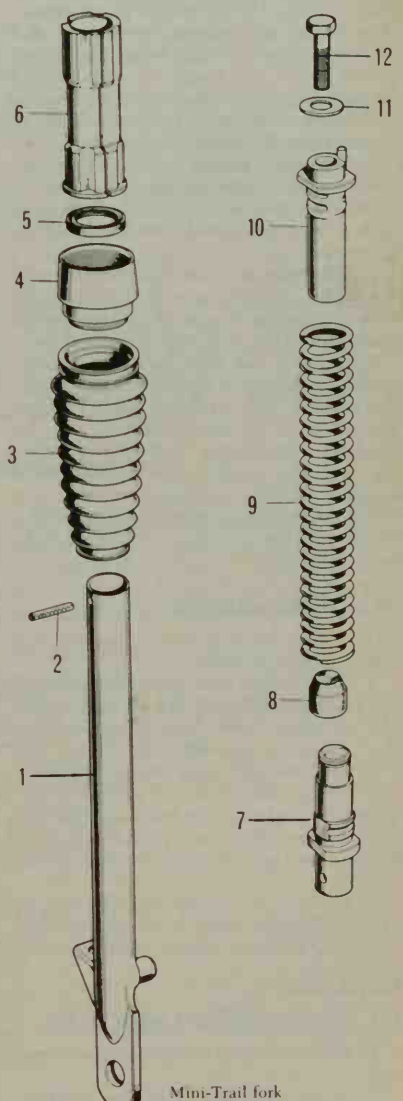
The mini-trail fork does not contain oil.

1. Remove the front wheel.

2. Remove the front fender.

3. Remove the bolt at the top of each fork leg and the steering stem nut.

4. The fork leg can be removed from each side after unscrewing the front fork guide cap with a chain wrench.



ALL OTHER MODELS

1. Loosen the fork filler caps located at the top of each fork leg.

2. Support the front wheel off the ground by placing a crate or another suitable object beneath the engine.

3. Remove the front wheel. Remove the fender.

4. Loosen the pinch-bolts on the upper and lower triple clamps, and remove the fork legs one at a time by pulling them straight down. If the fork legs resist removal, spread the lower triple clamp with a wedge and tap the fork leg out with a soft faced mallet.

Disassembly

MINI-TRAIL FORK

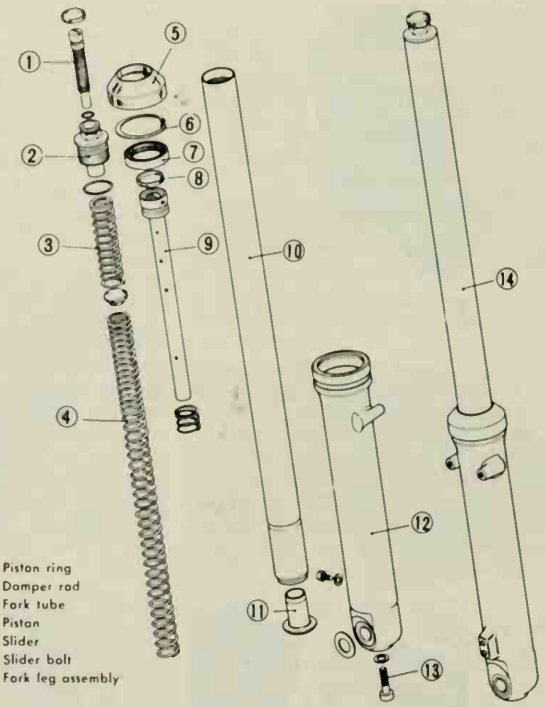
1. Fix the fork assembly in a vise by the upper holder. Strike the spring with a drift to remove it from the upper holder. Do not damage the upper holder as this is done.
2. Separate the spring from the lower holder in the same manner as above.
3. Using a small drift, push out the pin which secures the under holder and piston to the fork slide pipe.

TL125

The procedure is given for one fork leg, but it applies to both.

1. Remove the filler cap from the top of the fork tube and pour the oil into a suitable container to be disposed of.
2. Remove the spring(s) from the top of the tube.
3. Turn the fork upside-down and rest it on a block of hardwood. With an impact driver and the proper bit remove the allen bolt from the bottom of the slider. These bolts are installed with thread locking compound and trying to remove them without an impact driver will result in rounding the head of the bolt.
4. When the bolt is removed from the bottom of the slider, the damper rod complete with piston ring, and the rebound spring can be removed from the top of the fork tube.
5. The tube can now be pulled out of the slider. The piston will remain in the slider. Once the tube is pulled out the oil seal in the slider will have to be replaced.
6. Remove the dust cover and snap-ring from the top of the slider and pry out the oil seal with a hooked tool. The pin wrench from the Honda tool kit may be used by slipping the hooked end under the seal and tapping the handle with a hammer. A strip of copper or other soft metal can be used between the top of the slider and the handle of the wrench to protect the slider.

ALL OTHER MODELS

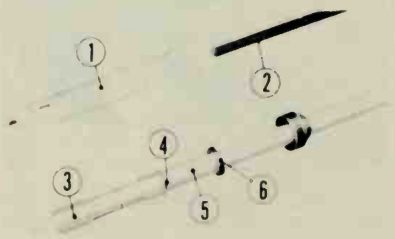


The procedure is given for one fork leg, but it applies to both.

1. Remove the filler cap from the top of the fork leg and pour the oil into a suitable container to be disposed of. Remove the fork spring (pre-76).
2. Remove the dust seal, snap-ring, and washer from the top of the slider. Grasp the slider in one hand and the fork tube in the other and pull them apart with a sharp jerk. Remove the fork spring (76).
3. Remove the circlip from the bottom of the fork tube, then the piston, two circlips, the sliding bushing and oil seal.

Inspection

ALL MODELS EXCEPT MINI-TRAIL



1. Wash all metal parts in a solvent and dry.
2. Inspect the fork slider for cracked, broken, or distorted axle brackets, worn inner bore surfaces, damaged threads, or dents which have affected the inner bore. Replace the slider if defective in any of the above ways.

3. Inspect the fork tubes for condition: the chrome plating must be intact throughout. Check for damaged threads, and worn or scuffed inner or outer surfaces. Check the tubes for straightness. This is done by placing the tubes in a set of V-blocks and checking the run-out with a dial gauge. If the tube is bent more than 0.060 in. as indicated by the gauge, it must be replaced.
4. TL125 only: Inspect the piston ring for wear or scoring.
5. Check the filler cap O-ring for cracks or any other signs of wear; replace it if damaged.
6. Check the general condition of the fork springs. Replace any which are badly rusted, have collapsed coils, etc. Compare the lengths of corresponding

springs. They should be of approximately equal length. If the springs differ in length by more than ¼ in., both springs should be replaced.

7. All except TL125: Inspect the inside surfaces of the piston and sliding bushing for signs of wear or score marks. Replace as necessary. Place the sliding bushing on the fork tube and check for excessive play. The bushing should be a close fit.

8. Coat all parts with ATF before assembly. New oil seals must always be used.

MINI-TRAIL FORK

1. With the fork assembled, compress the fork and check for proper operation. Note any noise and correct the condition causing it.

2. Compare the free-length of the springs. If the springs differ in length by more than ¼ in., both should be replaced.

Assembly

TL125

1. Be sure that the piston is in the slider. Lubricate the new oil seal with ATF and install it into the top of the slider. Place a block of hardwood over the seal and drive it straight into the slider as far as possible. Then place the old seal on top of the new one and drive them in until the new one clears the snap-ring groove in the slider. Take out the old seal. Be sure that the new seal is straight in the slider. The distance from the top of the oil seal to the snap-ring groove should be the same all around the seal. Install the snap-ring. Lubricate the lips of the seal.

2. Install the rebound spring and damper rod in the fork tube. Carefully install the slider on the tube. Replace the fork springs and cap temporarily. Turn the fork upside down and install the bolt in the bottom of the slider. The threads of this bolt should be coated with thread locking compound.

3. Fit the drain plugs; be sure to install the gaskets.

4. Remove the cap and fill the forks with the proper amount of ATF. Note that the amount added to rebuilt forks will be slightly more than for a normal fork oil change.

5. Refit the fork tubes through the triple clamps. The top of the fork tube should be even with the top of the upper triple clamp.

6. Tighten the pinch-bolts on the lower triple clamp, and then tighten the fork filler caps and the pinch-bolts on the upper triple clamp, in that order.

7. Fit the front wheel and check the operation of the forks.

8. Adjust the forks by means of the adjusting screws at the top. Turning the screws in will stiffen the suspension and vice versa.

MINI-TRAIL FORK

1. Assembly is in the reverse order of the disassembly, however, note the following points:

a. When the fork leg is assembled, the locating pin on the upper holder must be perpendicular to the axle mounting lug on the slide pipe;

b. Secure the upper holder and piston to the fork slide pipe with the pin. Coat the upper and lower holders with a thin coat of grease and install the spring;

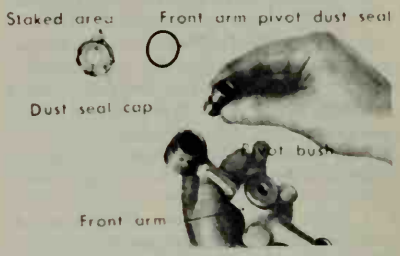
c. Fit the forks to the steering stem, noting that the locating pin on the top of the fork leg must fit into the slot in the top of the steering fork.

ALL OTHER MODELS

1. Install a new oil seal on the fork tube. Be sure to lubricate the seal with ATF before placing it on the tube.

2. Install the sliding bushing on the tube with the flange on the bushing facing the top of the tube. Install the two circlips, piston, and bottom circlip. All of the circlips must be a snug fit on the fork tube; if not replace them. Slide the fork spring into the tube from the bottom.

3. Place the fork tube into the slider and drive the oil seal into its seat in the top of the slider. Replace the washer, snap-ring, and dust seal.



4. Fill the fork leg with the proper amount of ATF. Replace the top washer, O-ring, and filler cap.

Leading Link Type Forks

DISASSEMBLY

1. Remove the front wheel.

2. Remove the 6 mm lockpin and the 7 mm locknut, then remove the front cushion joint washer and joint rubber. The front cushion and suspension arm can be removed as a unit by removing the front arm pivot bolt and the hex bolt.

Pivot dust seal

3. Remove the front arm rebound stopper by removing the 8 mm hex nut and bolt.

4. Separate the front cushion and the front suspension arm by removing the 8 mm hex nut and the front cushion lower securing bolt. Take care not to loose the front cushion lower dust seal cap, seal, and spacer collar. The dust seal can be removed by unlocking the staking.

5. The suspension unit is now ready to be dismantled. The lower portion of the cushion is a sealed unit which cannot be rebuilt, and which must be replaced if weak or damaged. Disassemble the cushion by removing the locknut and spring. The spring guide, seat, stopper rubber, and outer collar are now free to be removed.

INSPECTION

1. Clean all parts in a suitable solvent and blow them dry. The dust seals should be replaced as a matter of course.

2. Inspect the damper unit for oil leaks, warpage, or inefficient damping characteristics, and replace them if necessary.

3. Inspect the suspension and fork components for a worn or damaged condition and replace them as necessary. If the fork legs are bent slightly they can usually be straightened.

4. Measure the free-length of the spring and replace it if collapsed, worn, or damaged.

ASSEMBLY

1. Assembly is basically the reverse order of disassembly.

2. Lubricate the suspension arm with grease and apply engine oil to the dust seal.

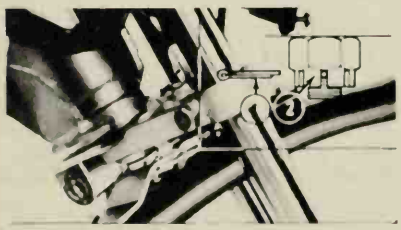
3. Lubricate the assembly when the assembly process is complete, by applying grease through the grease fitting using an automotive type grease gun.

STEERING STEM ASSEMBLY

Bearing Adjustment

1. The steering stem bearings are un-

caged #6 steel balls. They are adjusted by means of a ring nut beneath the upper triple clamp.



2. To check the bearing adjustment, support the front wheel off the ground. Grasp the fork sliders with both hands.

3. Attempt to move the forks by pulling out on the sliders. If play or movement can be felt, the bearings are too loosely adjusted or worn.

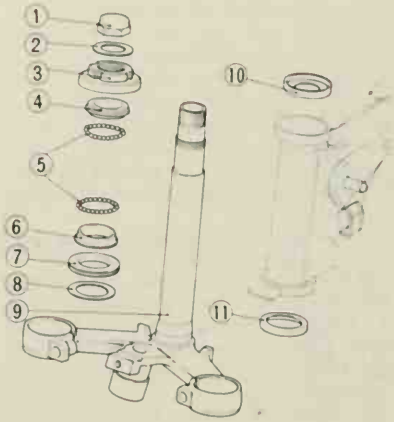
4. Turn the forks slowly from the lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and the races are either too tightly adjusted, unlubricated, or are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged, or some are missing.

5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The forks should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

6. Bearings can be adjusted with a hammer and punch or a pin wrench on the adjuster nut under the upper triple clamp after the triple clamp is removed. To do this, remove the handlebars; on CT/ST90 models remove the handlebar clamp lever by removing the cotter pin and nut from the bottom of the clamp under the lower triple clamp, and remove the handlebars. Remove the fork filler caps, loosen the two or three triple clamp pinch-bolts (if fitted) and remove the steering stem nut. Tap the underside of the triple clamp upward to remove it.

On CT/ST90 models, remove the handlebar clamp lever by removing the cotter pin (1) and the nut (2)

7. Tighten or loosen the adjusting nut a little at a time until the steering stem adjustment conforms to that outlined above.



8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Removal

1. Remove the front wheel, fender forks, fuel tank, handlebars, and the handlebar clamp on ST90 models.

2. Disconnect the speedometer and tachometer cables from the instruments (if fitted). Remove the headlight lens and disconnect the wire harness. Remove the headlight shell, speedometer, and tachometer.

3. Loosen the upper triple clamp pinch-bolts (if fitted). Remove the steering stem nut and washer. Tap the upper triple clamp upward with a plastic mallet to remove it.

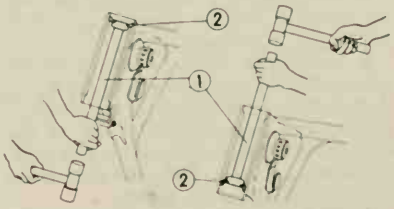
4. Upper race
5. Ball bearings
6. Lower race
7. Dust seal
8. Washer
9. Lower triple clamp and steering stem
10. Upper frame race
11. Lower frame race



4. Loosen the steering stem bearing adjuster nut with a pin wrench, then hold the steering stem up while unscrewing the adjuster nut the rest of the way off. Remove the steering stem top cone race and the balls from the top race.

5. Carefully pull the steering stem out from the bottom. Some of the ball bearings from the lower race will most likely fall out at this time so be prepared for this. Remove the rest of the balls from the lower race when the stem is removed.

6. Remove the bottom cone race, dust seal, and dust seal washer from the steering stem if they are to be replaced. If the steering stem has been damaged and is to be replaced, the upper and lower races and balls should also be replaced.

NOTE: *A chisel is usually necessary to remove the lower cone race from the steering stem.*

7. The bearing races in the frame are a press-fit and should not be removed unless replacement is necessary. Inspect them first. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable punch and tapping the races out from the inside of the lug.

Using a bearing driver (1) to remove the bearing races in the frame

New races are installed using a suitable sized bushing driver: i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.

These races can also be installed using a block of hardwood, of sufficient size to cover the race, in place of a bushing driver.

Inspection

1. Wash the bearings in a suitable solvent.

2. Clean all of the old grease from the bearing race surfaces, the steering stem, and the frame lug.

3. Inspect the bearing race surfaces. They must be clean and smooth. That is, free from any cracks, scoring, indentations, or rust. Run your finger around the bearing race surfaces. Note any roughness or ripples on the race surfaces. If either is damaged, replace both races and balls.

4. Check the balls themselves for rust, pitting, or flat spots. Replace the bearings as a set if any such damage occurs.

5. Check the dust seal for condition and replace if necessary.

6. Check the steering stem for cracks or a bent condition; this is especially important if the bike has been involved in a spill.

Installation

1. Install the dust seal washer, dust seal, and bottom cone race onto the steering stem. Use a good grade of bearing grease to coat the bottom cone race and the top race in the frame lug.

2. Embed the balls into the grease of the top frame race and the bottom cone race. Place a coat of grease on the two remaining races.

3. When the balls are in place, slip the steering stem through the frame lug and hold it in place, while refitting the top cone race and threading on the adjuster nut.

4. Tighten the adjuster nut, and move the steering stem back-and-forth to work the grease into the bearings, then back off the adjuster nut until the steering stem turns with ease, but has no play.

5. Install the upper triple clamp and fork tubes. Check that the stem moves freely of its own weight from 5°–10° off center; if not check for:

a. Steering bearings too tight;
b. Bent steering stem;
c. Worn races or balls.

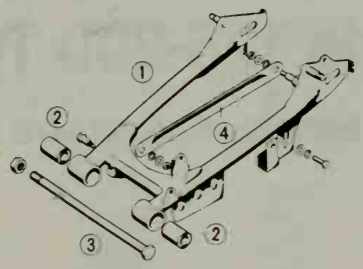
6. Install the flat washer, and steering stem nut.

7. Install the front wheel, front fender, headlight bracket, handlebars, and fuel tank.

REAR SHOCKS

No service to the rear shocks is possible. In the event of oil leaks, bent or broken plunger shaft, dented or otherwise damaged case, the shock absorber must be replaced.

If the shock absorbers are somewhat old, and one fails in the course of normal usage (such as an oil leak) it would be wise to replace both shocks to ensure equal damping characteristics.



To check a shock which is removed from the machine, place the bottom end

on the ground and use the weight of your body to compress it as much as possible. Release the shock and note its rebound behavior. If the shock returns quickly at first, then slowly returns to its normal length, it is serviceable. If it returns to its normal length all at once, it should be replaced.

SWING ARM

Inspection

1. Disconnect the drive chain. Remove the rear wheel.
2. Remove the shock absorbers and chain guard.
3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced.
4. Check that the rear wheel mounting plates are parallel.

Typical swing arm assembly

1. Swing arm
2. Bushing
3. Pivot bolt
4. Brake anchor

5. Grasp the legs of the swing arm and attempt to move it from side-to-side. Any noticeable side-play will indicate that the swing arm bushings need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

Removal and Installation

1. Proceed as above. Then remove the swing arm pivot bolt nut, and pull the pivot bolt out from the right-side.
2. Remove the swing arm by pulling it straight back.
3. The swing arm should be inspected for cracks or fractures, especially around the welds.

After removal of the swing arm, the dust seals (if fitted), and bushings can be replaced. This should be done every 10,000 miles, or more often depending on how the machine is used, or if the bushings are worn (see "Inspection").

4. Remove the bushing(s), tapping them out with a hammer and punch. Once the bushings are removed, they should be replaced.
5. Lubricate new bushings with a good chassis grease. Press the bushings into the swing arm, then install the swing arm collar if fitted.
6. Install the swing arm on the machine. Grease and install the pivot bolt. After tightening the swing arm pivot bolt nut, move the swing arm up and down to ensure that movement is smooth and effortless.

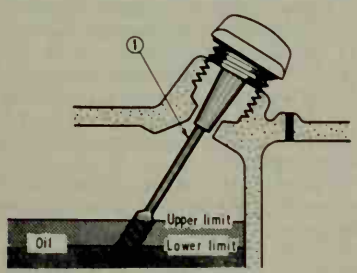
MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*



LUBRICATION

Checking Oil Level

The oil level is checked with the dipstick incorporated into the filler cap. The filler cap is located in the right crankcase cover. To check the oil level:

1. Start the engine and allow it to warm up for a few minutes.
2. With the motorcycle on the center stand on level ground, remove the dipstick and wipe it clean.
3. Reinsert the dipstick, allowing it to rest on the top of the threads of its hole. The oil level should be between the maximum and the minimum marks on the dipstick. If the level is below the minimum mark, add enough oil through the filler hole to bring the level up to the maximum mark.

CAUTION: *Do not overfill.*

When checking oil level, the dipstick should rest on the threads as shown

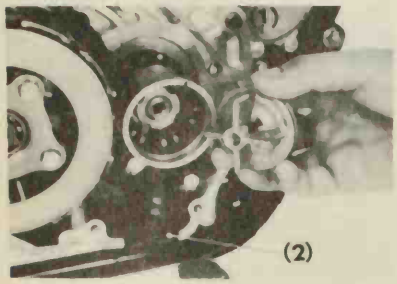
Changing Oil

Oil should be changed every 1,500 miles or at three-month intervals, whichever comes first.

Use oil with a service rating of "SE" only. SAE 10W-30 or SAE 10W-40 may be used at most temperatures. For temperature extremes, refer to the "Recommended Lubricants" chart at the end of this section.

1. Allow the engine to run for a few minutes until it is close to operating temperature.
2. Remove the dipstick, then place a pan under the engine to catch the oil. Remove the drain plug from the sump, and allow the oil to drain for a minute or two, then kick the engine over a few times with the kick-starter (be sure that the key is off) to remove any oil remaining in the delivery system.
3. Refit the drain plug and add oil according to the "Maintenance Data" chart. Run the engine for a minute or two, then shut it off; wait one minute and check the oil level. Add oil as necessary to bring the level up to the maximum mark on the dipstick.

Drain plug location (arrow)



Oil Filter

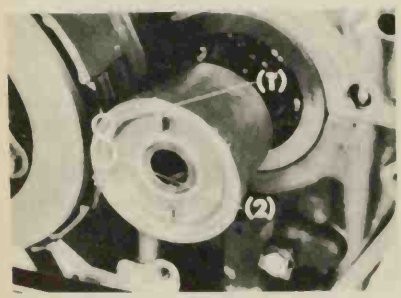
All models use two oil filters. The centrifugal oil filter mounted on the right end of the crankshaft should be cleaned every 6,000 miles or every 12 months. The oil filter screen located at the bottom of the oil pump should be cleaned and inspected at more extended intervals. The centrifugal oil filter on 125 and 175 models can be cleaned through the access cover plate on the right crankcase cover. The centrifugal filter on 200 models and the filter screen on all models can only be cleaned after removing the right crankcase cover.

1. Clean the filter in conjunction with an oil change. Drain the oil as previously described and install the drain plug but do not fill with oil at this time.
2. 125, 175 models: Remove the three screws from the access cover plate on the right crankcase cover and remove the cover plate.
3. 200 models: Remove the right muffler (CB models), and the kick-starter lever. Remove the two screws from the chrome access cover on the right crankcase cover and disconnect the clutch cable. Place a pan beneath the right crankcase cover. Loosen the cover screws with an impact driver and remove them. Tap the cover gently with a plastic mallet if necessary to free it, and remove the cover.

Loosen the rear brake adjusting nut so that the brake pedal can be depressed enough to allow the crankcase cover to clear.

4. Remove the screw from the center of the filter cap. Remove the cap with a pliers.
5. Clean the inside of the filter rotor with a clean rag and solvent.
6. Clean the filter cap and cover plate (125, 175) and dry thoroughly. Inspect the

Remove the cap, and clean out the rotor (1) and filter screen (2) (200)



O-ring on the filter cap and replace it if damaged in any way.

7. Inspect the oil guide in the cover plate (125, 175) or in the right crankcase cover (200). The guide should be free to move in and out and have sufficient spring force behind it to hold it against the filter cap.

8. 200 models: The filter screen can be pulled off of the bottom of the oil pump. Clean the filter screen in clean solvent and blow dry. Inspect the screen mesh for any puncture holes, if any are noted the screen should be replaced.

9. 125, 175 models: Install the filter cap with the vanes located in the grooves on the inside of the filter housing, and secure with the screw.

10. 200 models: Install the filter cap with the tab on the filter cap aligned with the mark on the filter rotor, secure in place with the 6 mm screw.

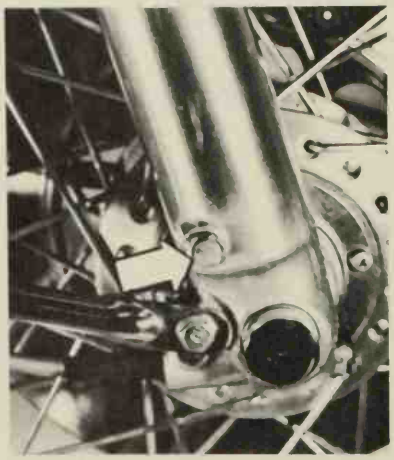
On 200 models, align the tab on the filter cap (2) with the punch mark on the filter rotor (1)

11. 125, 175 models: Install the cover plate using a new O-ring if necessary.

NOTE: *When installing the cover plate on 125 and 175 models be sure that the oil passages in the cover plate and the right crankcase cover line up.*

12. 200 models: Install the right crankcase cover. Before installing the cover, check the condition of the gasket, and replace it if nicked or damaged. Install the kick-starter lever making sure to line up the punch marks on the shaft and the lever, if marks are fitted.

13. Fill the crankcase with oil.



Front Forks

1. Fork oil should be changed every 6,000 miles or every 12 months.

2. Refer to the "Recommended Lubricants" chart for the correct oil for your model.

3. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Allow the oil to drain for several minutes into a suitable container, then pump the forks up and down several times. After most of the oil is expelled, turn the forks all the way to the right to completely drain the right fork leg, or all the way to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit the drain plug and tighten it securely.

4. Repeat the procedure with the other fork leg.

Fork drain plug (arrow)

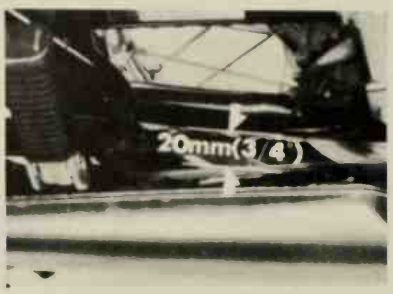
Fork filler cap (arrow)

5. Support the front wheel off the ground. Remove the fork filler cap from the top of each fork leg; it may be necessary to remove the handlebar holders and place the handlebars out of the way. Loosening the upper triple clamp pinch-bolts may make removal easier. On models with internal fork springs, the front end of the motorcycle can be lowered to force the springs out of the fork tubes. Either move the spring to one side or remove the spring altogether (if possible) to aid filling the forks.

6. Add the correct amount of oil to each fork leg. Capacities for each model are given in the "Maintenance Data" chart.

7. Inspect the condition of the fork filler cap O-ring, and replace it if it is torn or cracked. Fit the caps and tighten them securely. Tighten the handlebars and pinch-bolts if they were loosened. Allow a moment for the oil to settle in the forks before operation.

Chassis Lubrication



1. The swing arm pivot on some models is fitted with a grease nipple. This item should be lubricated with a good grade of chassis grease every 3,000 miles. Grease should be applied until some of it shows at either end of the swing arm.

2. Wheel and steering head bearings are lubricated with bearing grease. This should be done every 6,000 miles. Refer to the "Chassis" section.

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.

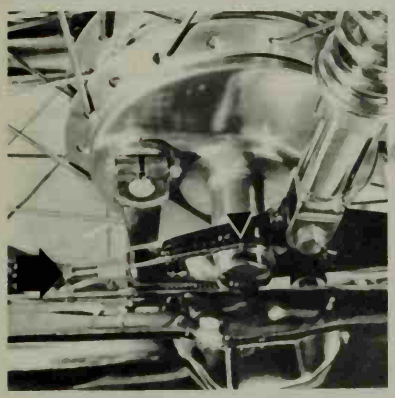
The chain should have the illustrated amount of free-play

2. Before checking or adjusting the chain slack, the following conditions should be met:

a. A support should be placed under the engine if necessary so that the rear wheel is off the ground;

b. The transmission should be placed in Neutral;

c. The chain should be cold, clean, and well lubricated;



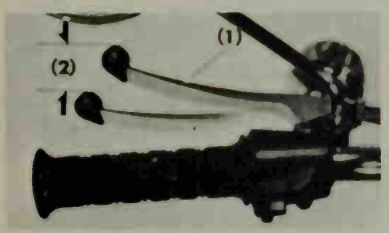
d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably sprockets which should be replaced as soon as possible.

3. To adjust the chain, first back off the rear brake adjuster nut if a rod-operated brake is fitted.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknuts on the chain adjusters.

5. Turn each of the adjuster bolts in or out by an equal amount until the chain tension is approximately correct.

6. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side.



Chain adjuster bolt (arrow) and alignment marks (triangle)

7. Tighten the axle nut and check the chain tension. Then check the tension with the weight of a rider on the machine; there must still be at least ½ in. of slack. Correct if necessary. Tighten the axle nut to the proper torque and fit a new cotter pin. Tighten the locknuts on the chain adjusters.

Clutch

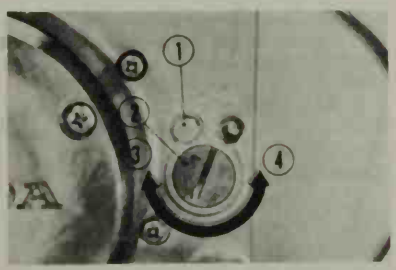
There are two adjusters on the clutch cable. Cable free-play should be maintained at 10–20 mm (0.4–0.8 in.) of hand lever movement measured at the end of the lever as illustrated.

Clutch lever free-play (2) should be maintained at 10–20 mm (0.4–0.8 in.), measured at the tip of the lever

Use the adjuster at the hand lever for routine adjustments; the one at the engine can be used for major adjustments.

The clutch release mechanism should be adjusted every 3,000 miles or 6 months, or whenever the clutch begins to drag or slip and satisfactory operation cannot be obtained by adjusting free-play at the lever. At the time of adjustment, lubricate the grease fitting (125, 175); one or two shots of the grease gun should be sufficient.

1. Screw the cable adjuster at the clutch lever all the way into the lever housing (increasing lever free-play).



2. Back off the locknut and turn the cable adjuster at the engine case into the case (increasing cable free-play to maximum).

3. 200 models: Remove the two screws from the chrome access cover on the right crankcase cover, and remove the cover.

4. Loosen the clutch adjuster locknut (200) or bolt (125, 175), and turn the adjuster clockwise until resistance is felt.

Clutch adjuster locknut and adjusting screw (200)

On 125, 175 models, loosen the lockbolt (1) and turn the adjuster (2) to adjust the clutch

Then turn the adjuster in the opposite direction (counterclockwise) about ⅛–¼ turn on 125, 175 models and ¼–½ turn on 200 models and tighten the locknut (200) or bolt (125, 175).

5. Unscrew the lower cable adjuster out of the engine case until the proper free-play of 10–20 mm (0.4–0.8 in.) is obtained measured at the tip of the lever. Tighten the locknut. Minor adjustments can be made with the adjuster at the clutch lever.

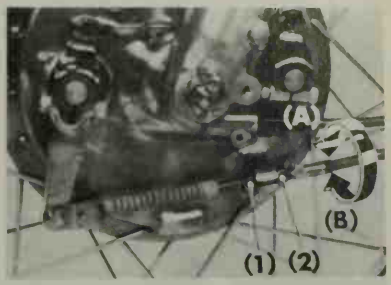
Throttle Cable

The throttle cable free-play should be adjusted *after* the idle speed. This procedure is given in the "Tune-Up." The standard throttle cable free-play is 10–15° of grip rotation for all models. The cable should be well lubricated before attempting to adjust the free-play.

1. Cable free-play is adjusted with the adjuster near the twist-grip. Loosen the locknut on the adjuster and screw the adjuster in or out until free-play is correct. Tighten the locknut.

2. Check that the cable operates smoothly and maintains some free-play when the handlebars are cut all the way to the right or left.

Front Drum Brake



1. Use the cable adjuster on the brake plate to allow about 20–30 mm (0.8–1.2 in.) of handlebar lever free-play before the shoes contact the drum. This free-play is measured at the tip of the lever.

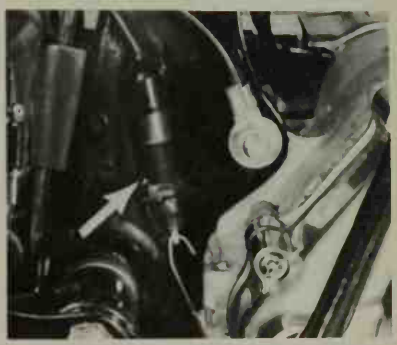
2. This free-play can be maintained as the shoes wear by using the adjuster at the handlebar lever.

Front Disc Brake

1. The handlebar lever should have 20–30 mm (0.8–1.2 in.) of free-play before the pads contact the disc.

2. The brake cable is self-adjusting; if service is necessary refer to "Chassis."

Front brake cable adjuster (2) and locknut (1). Turning the adjuster in direction "A" will take up excess lever free-play.



Rear Brake

Use the adjusting nut on the end of the brake rod so that the brake pedal has 1 in. of free-play before the shoes contact the drum. The pedal height can be adjusted with the brake pedal stopper bolt.

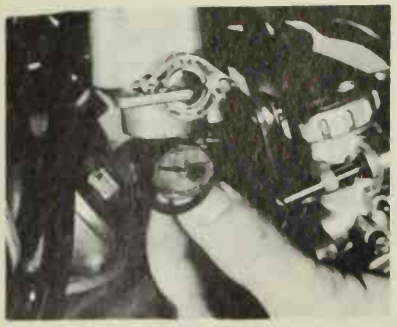
Brake Light Switch

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch is mounted in a slotted bracket and secured by locknuts. Moving the switch up on the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Do not turn the switch to adjust it as the wires will become twisted and may break. Generally, the brake light should come on just as the linings contact the drum.

The front switch is not adjustable.

Rear brake light switch

Steering Stem Bearings



The steering stem bearings should be checked periodically and adjusted if necessary. Refer to the "Chassis" section.

Fuel System

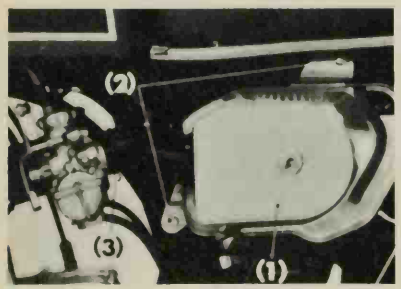
1. Fuel system maintenance involves cleaning the petcock and filter, cleaning or replacing the air cleaner, and cleaning the carburetors.

2. The carburetors should be removed, disassembled, and cleaned every 4,000 miles. The procedures are outlined in the "Fuel Systems" section.

3. The petcock should be serviced every 3,000 miles. Shut the fuel off, then unscrew and remove the petcock sediment bowl. Take out the O-ring and fuel

Removing the O-ring and filter screen

filter screen. Clean the parts in solvent and inspect the screen for any holes or other defects, replace it if it is damaged in any way. Inspect the O-ring for any cuts or cracks and replace it if necessary. Reinstall the filter screen, O-ring, and sediment bowl. Turn the fuel on and check for leaks.



Air Cleaner Service

The air cleaner should be serviced or replaced every 1,500 miles or more often depending on conditions.

ALL MODELS EXCEPT SL175

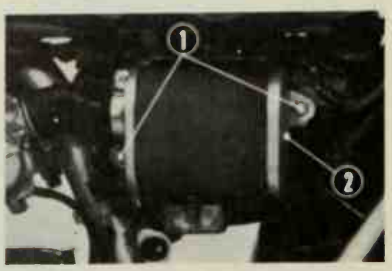
Removal

1. Open the seat. On CL models the exhaust system must be removed. Remove the right and left sidecovers.
2. Loosen the air cleaner connecting band. Remove the nut from the center of the air cleaner case, and remove the case.
3. Remove the two element mounting bolts and remove the element.

To remove the element (1), remove the mounting bolts (2)

Cleaning

1. Tap the air cleaner to remove any loose dirt. Blow compressed air through the element from the inside out.
2. Inspect the element and connecting tube for any holes; replace any air cleaner found defective. An oil-impregnated element or one which cannot be cleaned sufficently should also be replaced.
3. Inspect the area where the element is bonded to the mounting plate. If the bonding is cracked or separated replace the element.



Installation

1. Installation is in the reverse order of removal.
2. After installing the air cleaners, start the engine and check for any air leaks.

SL175

Removal

1. Remove the plastic sidecovers from both sides.

SL175 element mounting bolts (1 and 2).

2. Remove the two mounting bolts, and loosen the connecting band holding the carburetor inlet tube to the carburetor. Remove the air cleaner.
3. Remove the bolt from the center of the back of the air cleaner and remove the element.

Cleaning

1. Once the air cleaner element is removed, it should be cleaned in a clean solvent such as kerosene.
2. When the air cleaner element has dried thoroughly, soak it in clean motor oil SAE 30W until it is fully saturated then wring off the excess oil.
3. Inspect the element for any damage, such as holes or a damaged case. Replace any air cleaner found defective.

Installation

1. Installation is in the reverse order of removal.
2. Start the engine and check for any air leaks. Any air leaks should be corrected as they can cause a lean mixture resulting in possible engine damage.

Headlight Adjustment

1. Set the machine about 25 feet away from and perpendicular to a wall, preferably of a color which reflects light well.

The machine should be off the stand, and with a rider putting his weight on the machine as in operation.

2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.
3. Vertical adjustment is made by loosening the two headlight shell mounting bolts slightly and pivoting the shell up or down.
4. Lateral adjustment is accomplished by means of the screw on the right-side of the headlight. Turning the screw clockwise will move the beam to the left; turning it counterclockwise will move it to the right.

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in "General Information."*

CAM CHAIN ADJUSTMENT

175, 200

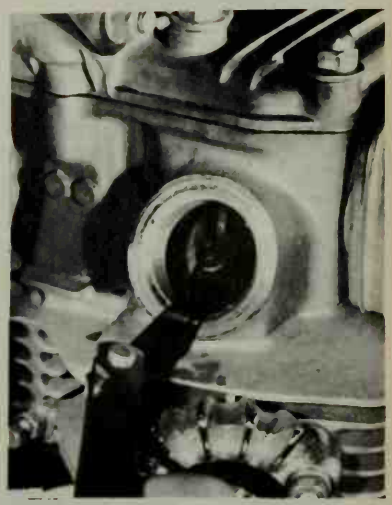
1. Remove the alternator cover.
2. Using a wrench on the alternator bolt, rotate the alternator rotor counterclockwise so that the "T" mark on the rotor is aligned with the timing index mark on the stator.

Rotor positioned at top dead center ("T" mark aligned)

Cam chain adjuster bolt (arrow)

3. Loosen the locknut on the tensioner setting bolt and back the setting bolt out three or four turns. The tensioner will automatically apply the correct amount of tension on the chain.
4. Tighten the setting bolt to a torque of 2–3.5 ft lbs, then tighten the locknut.

125



1. Remove the alternator rotor cover.
2. Remove the left-side intake valve cover.
3. Turn the alternator rotor clockwise (the opposite direction of normal rotation) until the left intake valve opens fully (spring compressed) and begins to close.
4. Turn the alternator rotor counterclockwise until the left intake valve barely moves.
5. Loosen the locknut on the cam chain adjuster bolt and turn the adjuster bolt (left-hand thread) clockwise so that the tension is removed from the chain. Now turn the adjuster screw counterclockwise until resistance is just felt. Tighten the locknut while holding the adjuster screw from turning.

CAUTION: *Do not over tighten the adjuster screw past the point where resistance is noticed or the tensioner and the chain will suffer premature wear.*

VALVE ADJUSTMENT

NOTE: *Valves must be adjusted when the engine is cold.*

1. Remove the alternator cover.
2. Remove the four valve tappet covers. The fuel tank can be removed for easy access to the tappet adjusters.
3. Remove both spark plugs.
4. Turn the crankshaft, using the rotor bolt, until the "T" mark on the alternator rotor is aligned with the timing index mark on the stator.
5. With the crankshaft in this position both cylinders will be at top dead center (TDC), however, one cylinder will be on its compression stroke and the other on its exhaust stroke. To determine which cylinder is on compression, check to see which pair of valves (intake and exhaust) are fully closed, in which case there will be clearance at both rocker arms. The valves for the cylinder which is on its compression stroke are correctly positioned for adjustment.
6. The correct valve clearance for both valves is 0.05 mm (0.002 in.). Slip the correct feeler gauge between the valve stem and the rocker arm adjuster. The feeler gauge should be a slip-fit (a slight drag), in a correctly adjusted valve.

Checking valve clearance

7. If adjustment is necessary, loosen the adjuster locknut and turn the adjuster to effect adjustment. Tighten the locknut.

NOTE: *The adjustment may change when the locknut is tightened. Hold the adjuster steady while securing the locknut. Recheck the clearance afterwards.*

8. Turn the rotor one full turn (360°) counterclockwise and line up the "T" mark with the timing index mark again. In this position the other cylinder will be on its compression stroke and both valves should be closed. Adjust the valve clearance as described in Steps 6 and 7 above.

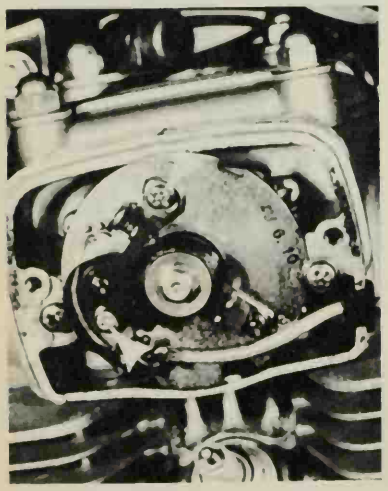
CONTACT BREAKER POINTS

Location

The points are located in a case on the left-side of the cylinder head, and are operated off the camshaft. The timing advance mechanism is fitted on the camshaft behind the breaker point base plate.

Replacement

1. If replacement of the points is necessary, this is easily accomplished by disconnecting the primary wire, removing the two point securing screws, and taking off the points. Install the new points after thoroughly cleaning off the contact surfaces with a non-oily solvent, and adjust the gap. If a breaker plate assembly is purchased, simply disconnect the pri-



mary wire from the wiring harness and remove the two breaker base plate screws. Install the new breaker base plate and connect the primary wire. Clean the surfaces of the points and adjust the gap. Whenever the points are replaced, the ignition timing will have to be set.

2. Apply a bit of grease to the breaker cam lubricating wick. Take care not to apply too much to avoid fouling the points.

Gapping

Points should be filed (if necessary) and cleaned before gapping.

1. Remove the alternator cover, and points cover.
2. Using the rotor bolt, turn the engine over until the points are open to their maximum gap.
3. With the proper feeler gauge, check the gap. The proper specification for all models is 0.3–0.4 mm (0.012–0.016 in.).
4. If adjustment is necessary, loosen the two screws which secure the points to

Points securing screws used to adjust point gap

the base plate and open or close the points to bring the gap to the proper specification.

NOTE: *Loosen the screws just enough to allow the points to be moved. If too loose, the points will snap shut instead of holding the adjustment.*

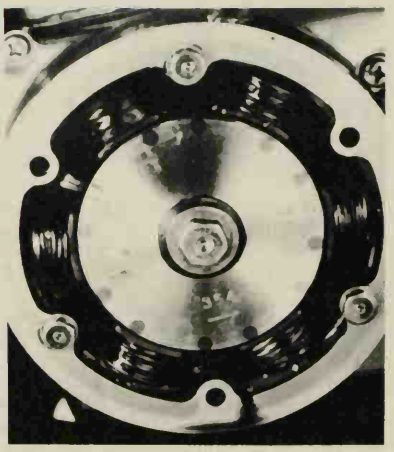
5. Tighten the screws and recheck the gap.
6. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the set of points should be replaced.

Lubrication

1. On all models it is necessary to lubricate the cam follower fiber heel and the pivot point of the contact breaker occasionally.
2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.
3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.
4. The lubricating wick should be adjusted so that it just contacts the breaker cam.
5. If the wick is missing the grease can be applied sparingly to the cam itself.

IGNITION TIMING

NOTE: *Points must be cleaned and gapped before checking timing. Dirty points will cause inaccurate readings.*



Dynamic Timing

1. Remove the alternator cover so that the timing marks are visible.

NOTE: *A white grease pencil or some paint can be used on the rotor and stator timing indicator marks to increase their visibility under the strobe light.*

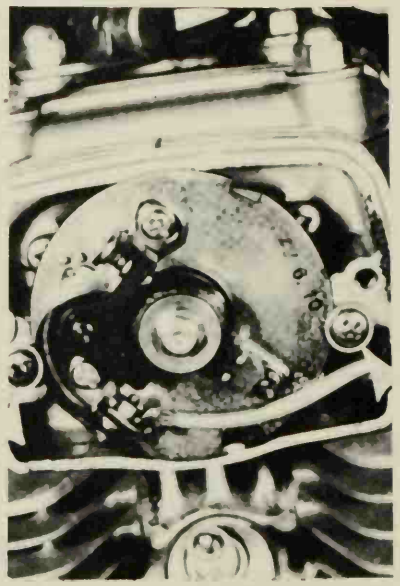
2. Hook up the timing light to either cylinder according to the manufacturer's instructions.
3. Start the engine, aiming the light on the rotor. Note the following:

a. At idle, the "F" mark on the rotor should line up with the timing index

Full spark advance timing marks aligned with pointer

mark on the stator;

b. As the revolutions increase, the "F" mark should be seen to move in a direction opposite that of the crankshaft rotation;

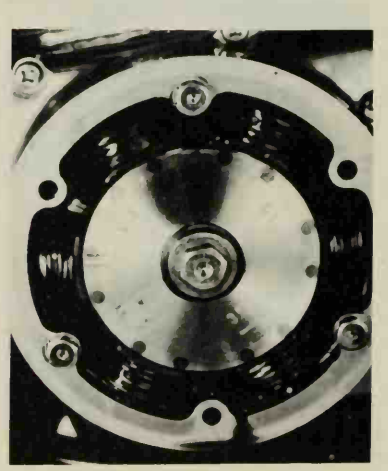


c. Finally, at full advance (about 4,000 rpm and above), the twin rotor marks must line up with the timing index mark.

4. The full advance reading is the most important. If the twin marks on the rotor and the timing index mark do not align, proceed as follows:
5. Loosen the two screws which secure the breaker base plate just enough to allow the plate to be turned. Rotate the base plate in the direction necessary so that the timing marks align.

Rotating the base plate clockwise advances the timing; rotating the plate counterclockwise retards the timing.

Tighten the base plate screws and recheck the timing.



If proper ignition timing is not possible, replace the points, since the fiber heel is probably worn.

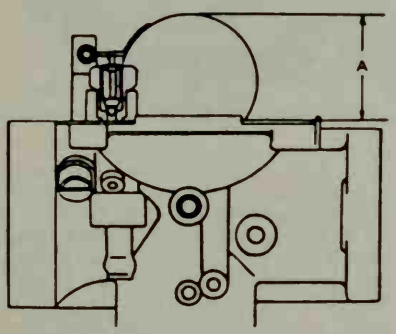
Breaker base plate screws

Static Timing

1. Remove the points cover, and the alternator cover.
2. Remove the spark plugs and hook up the tester as described previously.
3. Turn the engine over slowly in the normal direction of rotation (counterclockwise). At the instant in which the "F" mark on the rotor aligns with the index mark on the stator, the points should begin to open as indicated by the reaction of the test light or meter.

"F" mark aligned with the pointer

4. If the points open before the marks align, the timing is too advanced. If the points open after the "F" mark passes the index mark, the timing is too retarded.
5. If the timing is not correct, set the "F" mark so that it is aligned with the index mark. Loosen the two screws which secure the breaker base plate and rotate the plate until the light or the meter indicates that the points have just opened. Tighten the base plate screws and recheck the timing.



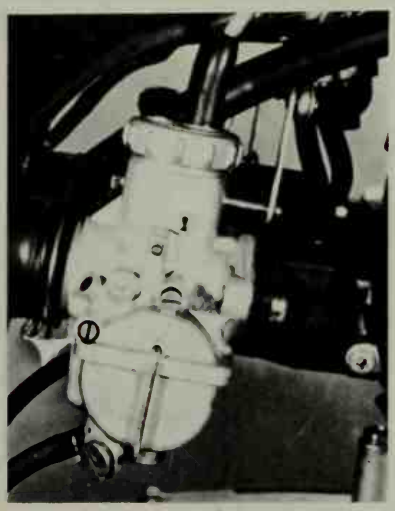
CARBURETOR

Three adjustments to be made to the carburetor are the float level, the idle mixture, and the idle speed. For the first of these, the carburetor must be removed from the motorcycle.

Adjusting Float Level

Generally, float level will not need adjustment unless the carburetor has been disassembled, fuel delivery problems have been noted, or considerable mileage has been covered.

1. Remove the carburetor from the motorcycle as outlined in the "Fuel Systems" section.
2. Remove the float bowl. Remove the float bowl gasket.
3. Float level is defined as the measured distance from the float bowl mating surface on the carburetor body (gasket removed) to the top of the floats, when the tang of the float arm is just touching the end of the float needle. A special gauge is available at Honda dealers to check the float level although a vernier caliper can also be used.



Float level is the distance "A" from the float bowl gasket surface (gasket removed) to the top of the floats

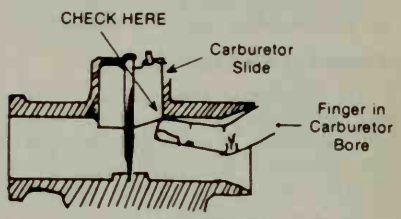
4. With the carburetor held upside down, gradually lower the float until the tang of the float arm just touches the end of the float needle. The tang should not depress the needle, but just contacts it. Measure the distance from the top of the float. Compare the reading with the proper float level for your machine.
5. If adjustment is necessary, bend the float arm tang *only* to raise or lower the float level.
6. Float level will not be correct if the needle is worn, or if there is foreign matter on the needle seat.

Idle Speed and Mixture

NOTE: *These items must be adjusted when the engine is at operating temperature.*

1. Ensure that the throttle cable adjustment is approximately correct so that the cable has enough slack to allow the throttle slides to be fully closed.
2. Screw the pilot screws in carefully until they bottom lightly, then back them out the number of turns shown in the "Tune-Up Specifications" chart.

Carburetor pilot screw (left) and throttle stop screw



3. Start the engine. When operating temperature is reached, adjust the throttle stop screws so that the engine idles smoothly at about 1200 rpm.
4. Place a hand behind each muffler to ensure that both cylinders are running evenly. If the idle speed and mixture adjustment screws are misadjusted, one cylinder may "lead" the other. Adjust the throttle stop screws, if necessary, so that both cylinders are running evenly.
5. Adjust each pilot screw so that the engine runs as smoothly as possible. It should not be necessary to vary the pilot screw setting more than ½ turn from the standard given.

NOTE: *If proper idling cannot be obtained using this method, it may be that the fuel system is clogged with dirt (check petcock, filter, carburetor), the plug is bad or too cold, the valves are improperly adjusted, or there is an air leak somewhere in the system.*

6. Check that the two carburetors are synchronized.

Carburetor Synchronization

1. Remove the air cleaner assembly.
2. Twist the throttle fully open to lift up the slides.
3. Position a mirror behind the carburetors or reach into the carburetor bores with the thumb and index finger of one hand.

Check for carburetor synchronization by ensuring that both slides clear the carburetor bores at the same time

4. Slowly close the throttle and watch, or feel, the slides as they are being lowered; they should enter their respective bores simultaneously.
5. If the slide positions are unequal, raise or lower one to match the other by turning the adjuster at the top of the carburetor.
6. Another check is to place a finger on each carburetor slide when the throttle is fully closed, then move the twist-grip very slightly. Both slides should begin to lift at the same time. Adjust as described above if necessary.
7. After adjusting the idle speed and synchronizing the throttle slides, adjust the throttle cable free-play.

ENGINE AND TRANSMISSION

NOTE: *For engine component inspection procedures and techniques, refer to "Engine Rebuilding" in the General Information section.*

Engine Service

1. To remove the cylinder head, barrels, and pistons, the engine must be removed from the frame.

2. Crankcase cover components: oil pump, clutch, gearshift mechanism, alternator, countershaft sprocket, and the cam chain tensioner (125 models), are all accessible with the engine in the frame.

Removal and Installation

1. Degreasing and thoroughly cleaning the engine before removal is highly recommended. Be especially attentive to the cylinder base and the underside of the crankcase, and around the mating surfaces.

2. Drain the oil from the sump, and reinstall the drain plug.

3. Turn the fuel petcock to the off position and disconnect the fuel lines from the petcock. Disconnect the balance line from the tank and remove the tank.

NOTE: *To safely remove the tank, either drain it completely prior to removal, or obtain a four inch length of fuel line and two small clamps. Attach one of the clamps to the fuel tank's balance line. Disconnect the lines; fit the spare length of fuel line to the fitting on the tank with the other clamp already attached. This will prevent fuel from spilling out of the tank when the fuel line is disconnected for removal.*

Step-bar mounting bolts (1) and step-bar (2) (125)

4. Remove the step-bar, and the exhaust system. On 125 models, remove the brake pedal spring and the stoplight switch spring.

5. Open the seat and remove the battery. When disconnecting the battery always disconnect the negative terminal first.

6. If an electric starter is fitted, disconnect the starter motor cable from the selenoid.

7. Unscrew the carburetor caps and pull the throttle slide assembly out of the carburetor.

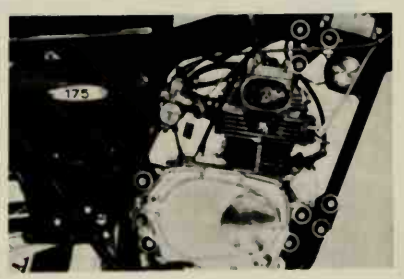
8. Disconnect the choke rod from the left carburetor. Loosen the band securing the air cleaner to the carburetor. Unbolt the intake manifold from the cylinder head and remove the intake manifold and the carburetors.

9. Remove the three phillips head screws from the left rear crankcase cover, and remove the cover.

10. Disconnect the drive chain.

Disconnecting the clutch cable (1) from the release mechanism (2) (125, 175)

11. 125, 175 models: Disconnect the clutch cable from the clutch release mechanism on the left-side of the engine.



12. 200 models: Remove the chrome cover from the right crankcase cover. Screw the clutch adjuster at the right crankcase cover in to allow some free-play in the cable. Disconnect the cable from the release mechanism.

13. Remove the cover on the right-side of the cylinder head. Remove the phillips head set screw and disconnect the tachometer cable from the engine.

14. Disconnect the alternator leads from the wiring harness at the plastic connector. Disconnect the point primary wire from the wiring harness.

15. Disconnect the spark plug leads, and loosen the plugs.

16. Remove the nuts from the engine mounting bolts, 4 on 125 models, 9 on 175, 200 models. Remove the mounting bolts being careful not to damage the

Engine mounting bolts (175)

threads on the bolts, then lift the engine out of the frame.

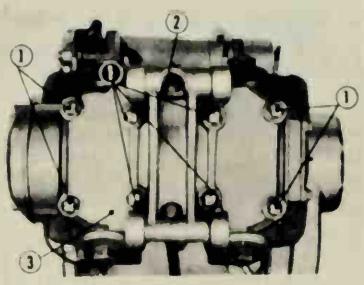
17. Installation is in the reverse order of the removal procedures, however, note the following points:

a. Install the battery ground cable to the rear upper mounting bolt. Scrape any paint or rust from the frame under the cable to ensure a good ground;

b. When connecting the battery, connect the positive terminal first. Route the battery overflow tube so that it will release any overflow (sulfuric acid) well below the frame and swing arm;

c. Install the throttle slide into the carburetor with the cutaway of the slide facing the air cleaner;

d. Install the masterlink spring clip with the closed end facing the direction of chain rotation.

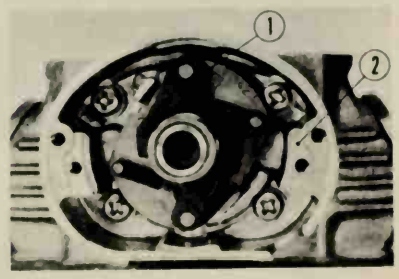


CYLINDER HEAD

Removal

175, 200

1. Remove the engine from the frame.



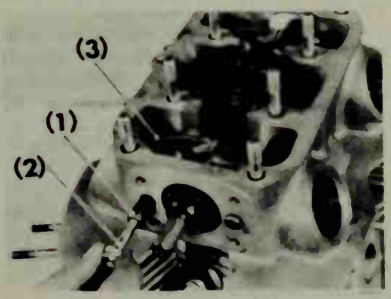
2. Loosen the eight 8 mm capnuts and the head bolt gradually and evenly in an X pattern about ¼ turn at a time until they are all loose, then remove them.

Cylinder head capnuts (1), bolt (2), and head cover (3)

3. Lift off the cylinder head cover, tapping it around the sides with a plastic mallet to break it loose if necessary.

4. Remove the two phillips head screws from the points cover and remove the cover. Remove the two 5 mm phillips head screws securing the point base plate to the point side housing, and remove the base plate. Remove the 6 mm bolt and flat washer from the end of the camshaft. Remove the spark advance unit from the end of the camshaft. Be careful when removing the spark advance unit that the breaker cam (point cam) is not pulled from the unit. If the cam is removed be sure to install it in the correct direction, it is possible to install the cam 180° off making proper ignition timing impossible.

Spark advance unit (1) and point base (2)



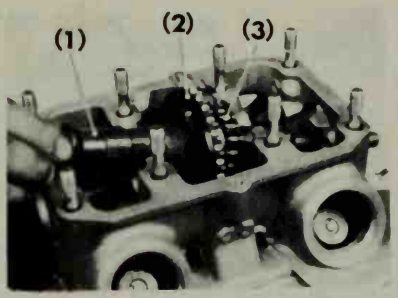
5. Remove the three screws from the alternator cover on the right-side of the engine and remove the cover. Remove the valve adjuster caps.

6. Loosen the cam chain tensioner set bolt.

7. 175 only: Using the alternator rotor turn the engine over until the cam chain masterlink is at the top of the cam sprocket. The "T" mark on the alternator rotor should be aligned with the timing index mark on the stator. Stuff a clean rag into the cylinder head around the cam sprocket and remove the cam chain masterlink. Tie a piece of wire or string to each end of the cam chain. At this point the cylinder head can be removed. If the head is stuck, tap around the base of the head with a plastic mallet to free it, take care not to break the cooling fins.

The following procedures refer only to 200 models.

8. Remove the four phillips head screws from the side housing on either side of the cylinder head. Using the alternator rotor bolt turn the engine over until the "T" mark on the alternator rotor is aligned with the timing index mark on the stator, in this position one of the cy'



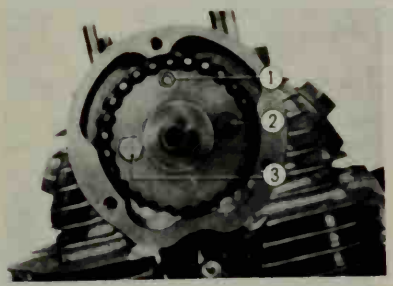
Using a 6 mm bolt (2) to remove the rocker arm shaft (1) and rocker arm (3) (200)

inders will be at top dead center (TDC) of its compression stroke. The intake and exhaust valves for this cylinder will be closed (clearance between the rocker arms and the cam). Remove the side housing on that side. Screw a 6 mm bolt into each of the rocker arm shafts, and pull them from the head. Remove the rocker arms. Temporarily install the side housing, but do not install the securing screws.

9. Turn the alternator rotor bolt one complete turn (360°) counterclockwise, this will position the other cylinder at TDC of its compression stroke. Remove the rocker arm shafts and the rocker arms, then install the side housing in the same fashion as before.

10. Turn the engine over with the rotor bolt so that one of the cam sprocket bolts is at the top of the sprocket, remove the bolt. Turn the alternator rotor one complete turn counterclockwise and remove the remaining sprocket bolt. Both the side housings can now be removed. Remove the dowel pin from the right-side of the cam.

11. Lift the cam chain off the sprocket and lift the cam and the sprocket out the top of the cylinder head from the right-side. Wrap a piece of stiff wire around the cam chain so that it does not fall down in to the crankcase. The cylinder head can now be lifted off. If the head resists removal tap around the bottom with a plastic mallet to free it, however, take care not to break the cooling fins.

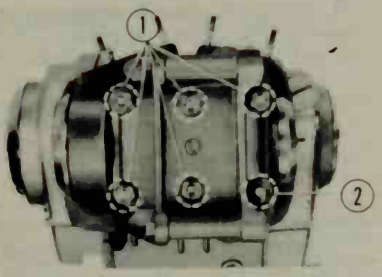


Lift off the chain (3) and remove the sprocket and cam (1 and 2)

125 MODELS

1. Remove the engine from the frame as described previously.

2. Remove the side covers from the sides of the cylinder head. Remove the two screws which secure the breaker point plate to the head and remove the plate. Remove the bolt from the left-side of the camshaft and pull the spark advancer unit off the cam.



The chain masterlink will be close to the sprocket "0" mark. To remove the sprocket, remove the bolts (2 and 3).

3. Remove three screws from the point base and remove the point base.

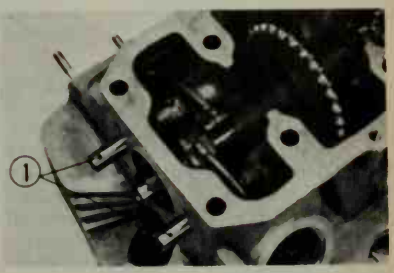
4. Rotate the engine so that the cam chain masterlink is located at the top of the cam sprocket.

5. Remove the two bolts which secure the cam sprocket to the camshaft. Remove the sprocket.

Cylinder head nuts (1) and capnut (2)

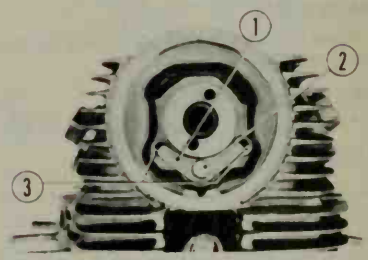
6. Remove the masterlink from the cam chain. Take care not to drop the masterlink into the cam chain passage. Fasten a piece of stiff wire onto each end of the cam chain, this will facilitate installation of the cam chain apon assembly.

7. Loosen the 6 head nuts gradually and evenly in an X pattern until they are all loose and then remove them and the breather cover.



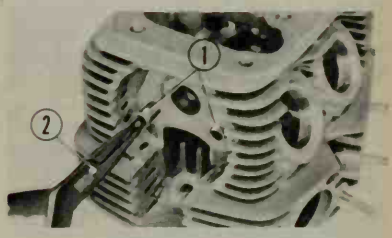
8. Lift off the cylinder head, tapping around the base of the head with a plastic mallet if necessary to break the seal.

Disassembly



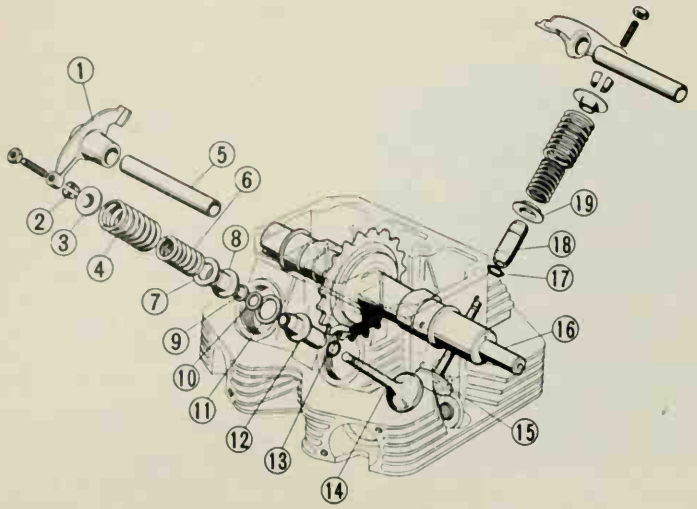
Disassembly of the head involves removing the camshaft, rocker arms, cam chain tensioner (175) and the valves on the 125, 175 models while on 200 models, only the cam chain tensioner and the valves remain in the head after the head is removed. Note, however, that the combustion chamber should be decarbonized and the sealing ability of the valves checked for all models before the valves are removed. Refer to the following inspection section for these procedures.

1. 175, 200 models: Remove the cam chain tensioner set bolt, and remove the tensioner push-bar and the tensioner spring.



2. 175 models: Loosen the valve adjusters so that there is clearance between the rocker arms and the cam. Remove the four screws from the right and left cylinder head side housings. Remove the side housings tapping them on the side with a plastic mallet if necessary. Pull the rocker arm shafts out of the head and remove the rocker arms. The cam can be lifted out of the head from the top.

Remove the rocker arm shafts (1) (175)



Remove the bolt (2) from the set plate (1) and remove the rocker arms (3) (125)

3. 125 models: Loosen the valve adjusters so that there is clearance at the rocker arms. Remove the bolt from the rocker arm shaft set plate and remove the plate. Pull the rocker arm shafts out of the head. Remove the rocker arms. Slide the camshaft out of the left-side of the head.

4. The valves can be removed after compressing the springs with a valve spring compressor and removing the

Cylinder head assembly (175). Other models are similar.

valve spring keepers. Remove the keepers, valve spring retainers, valve springs, and the spring seats. Where fitted, the valve seals should be removed from the guide and replaced with a new one upon assembly. All parts removed should be marked so that they can be installed in the same location they were removed from; this is especially important for the valves.

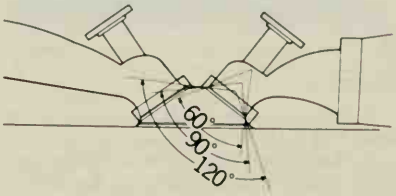
Inspection

Specifications are given in the charts at the end of this section.

CYLINDER HEAD

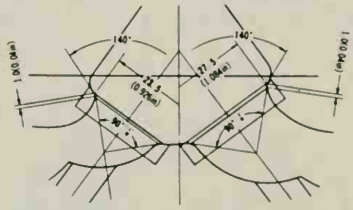
1. Maximum allowable mating surface warpage is 0.05 mm (0.002 in.).

2. 175, 200 models: Inspect the cam chain tensioner push bar and replace it if it is bent. Remove any burrs from the push bar with a file. Measure the free-length of the tensioner spring. If the spring is less than 80 mm (3.15 in.) in length, it should be replaced. Check the end of the set bolt and if it is deformed, the bolt should be replaced; this is a sign that the bolt has been overtightened.



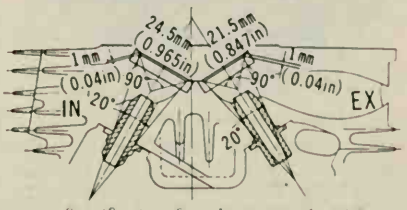
VALVES

1. Valve seat width should be about 1.0 mm (0.04 in.) all the way around.



2. Valve faces and tips have a stellite surface. Refacing or grinding the tip are not recommended. Replace unsatisfactory valves.

3. If the valve guides are to be replaced, they should be driven out from the combustion chamber side with a proper size valve guide driver, and replaced with an oversized guide. After the guide is installed the inside bore should be reamed to the proper size.



NOTE: *The valve seats are cut at an angle relative to the valve guide (45°), therefore, whenever the guides are replaced the valve seats should be refaced with a valve seat grinder to the specifications shown in the accompanying illustration, and the valves lapped into the new seats.*

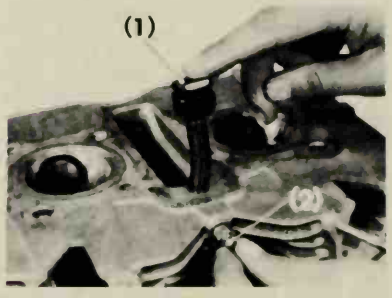
Assembly

1. All parts should be coated with clean motor oil or one of the newer assembly lubricants before installing them.

2. Install the valve into its guide after coating the stem with oil. Install the spring seat, and oil seal (if fitted). Install the inner and outer valve springs with



When installing the valve springs, be sure that the close coils are closest to the head

the close coils facing down (toward the head); the springs are progressively wound. Install the upper spring seat. Compress the springs with a valve spring compressor so that the keeper may be installed. Do not compress the springs more than is necessary to install the keepers. To do so may damage the valve guide or the oil seal (if fitted).

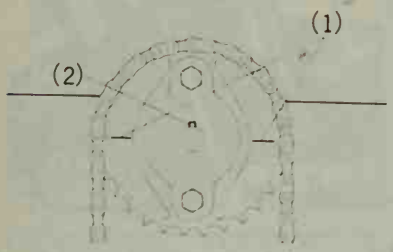
3. 125, 175: Install the camshaft into the head so that the "O" mark on the cam sprocket is at the top. It will be necessary to hold the cam sprocket in place on the 125 so that the cam can be installed properly. The two cam sprocket bolts are different types; be sure that the sprocket is positioned correctly and the bolts installed in the proper holes. Install the rocker arms and the rocker arm shafts and the set plate (125). On 125 models, once the cam is correctly positioned the sprocket can be removed.

4. 175, 200 models: Install the cam chain tensioner spring onto the push bar, then install the push bar into the head. Push the tensioner into the head as much as possible and tighten the set bolt.

Push the cam chain tensioner push bar in as far as possible and tighten the set bolt (175, 200)

Installation

200



1. Install a new head gasket onto the top of the cylinder. Be sure that the mating surface of the cylinder and the head are clean and free of any scratches.

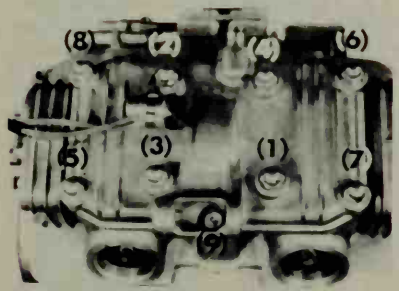
2. Install a guide pin to each of the outside cylinder studs (four total) and an O-ring to each of the outside rear studs.

3. Turn the crankshaft so that the "T" mark on the alternator rotor is aligned with the timing index mark on the stator. Hold the cam chain up when turning the crankshaft so it will not be jammed around the sprocket on the crankshaft. Be sure that the cam chain tensioner is pushed into the head as far as it will go. Install the head routing the cam chain

through the center. Slip a rod through the chain to keep it from falling down into the cylinder until the cam is to be installed.

4. Install the cam chain sprocket so that the aligning marks on the sprocket are parallel to the cylinder head mating surface.

Install the sprocket so that the aligning marks (1) on the sprocket are parallel to the mating surface. The pin for the advance unit (2) must be vertical when the cam is installed



5. Install the camshaft into the cam sprocket with the locating pin for the spark advancer pointing up. Install the two cam sprocket bolts into the cam, and torque to 12–16 ft lbs.

NOTE: *The two cam bolts are special bolts and should not be confused with a standard 6 mm bolt. It is recommended that these bolts be replaced with new ones once removed, and installed with a thread locking compound.*

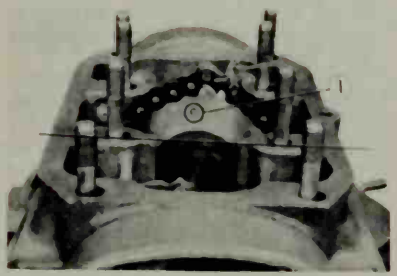
6. Install the rocker arms and the rocker arm shafts. Install the cylinder head side housing using new gaskets beneath them. Do not forget to prelube the camshaft bearings and the rocker arms and shafts.

7. Loosen the cam chain tensioner set bolt and recheck the valve timing. When, the "T" mark on the alternator rotor is aligned with the timing index mark on the stator, the aligning marks on the camshaft sprocket MUST be perfectly parallel to the cylinder head mating surface. If the marks are not parallel, remove the camshaft and reset the timing.

8. If the timing is correct, install the breather cover gasket and the breather cover. Install the cylinder head nuts noting that the condenser is mounted on the right center rear stud. Tighten the head nuts in the order shown in the accompanying illustration a few ft lbs at a time until all the nuts are torqued to 13–16 ft lbs.

Cylinder head tightening sequence (200)

9. Adjust the valve clearance and the ignition timing.



175

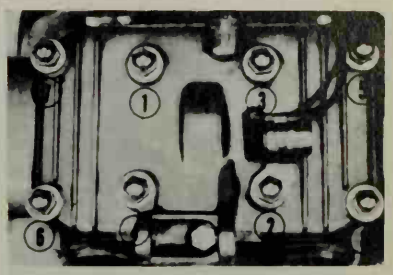
1. Install a new head gasket to the top of the cylinder. Install a guide pin onto each of the outside studs (4 total). Install an O-ring onto the rear outside guide pins.

2. Slip the cam chain through the cam chain passage in the head and lower the head onto the top of the cylinder.

3. Using the alternator rotor bolt, turn the engine over so that the "T" mark on the rotor is aligned with the timing index mark on the stator. When rotating the crankshaft, hold the cam chain up so that it does not jam up around the crankshaft sprocket. When the crankshaft is in position, position the chain so that both sides are equal length.

4. Install the cam so that the "O" mark on the sprocket is at the top of the sprocket (in a line with the crankshaft and camshaft), and connect the cam chain. When installing the masterlink spring clip, the open end of the spring clip MUST face the opposite direction of chain rotation. The cam rotates counterclockwise when viewed from the left-side.

With the "T" mark on the rotor aligned with the index mark, the "O" mark on the cam sprocket should be vertical as shown. Then install the cam chain masterlink (175)



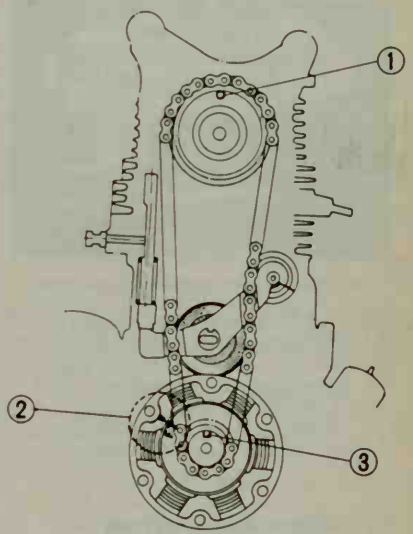
NOTE: *It would be a good practice to replace the cam chain masterlink once removed as a broken cam chain will usually cause quite extensive damage to the engine.*

5. Install the rocker arms, rocker arm shafts, and the cylinder head side housings. New gaskets should be used under the side housings. The rocker arms should be installed onto the same shafts that they were removed from.

6. Release the cam chain tensioner set bolt, the chain will automatically adjust itself. Tighten the set bolt and locknut. Recheck the valve timing. If the "O" mark on the cam sprocket is not at top dead center of the cam sprocket with the "T" mark on the alternator rotor is aligned with the timing index mark on the stator, the valve timing will have to be reset.

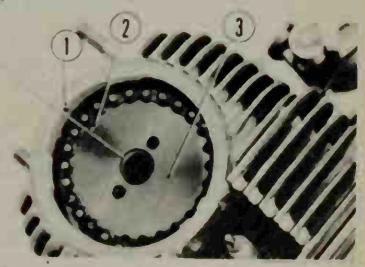
If the timing is correct, the breather cover gasket and the breather cover can be installed. Tighten the head nuts in the order shown in the accompanying illustration. Tighten the bolts in increments of a few ft lbs until they are all tightened to the proper torque of 11.5–14.5 ft lbs.

7. Adjust the ignition timing and the valve clearance



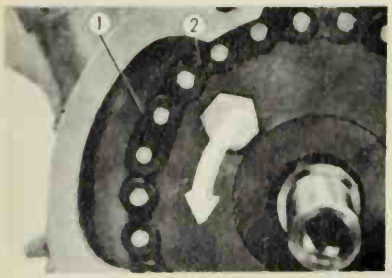
Cylinder head tightening sequence (175)

125



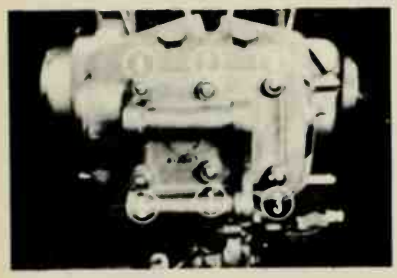
1. Install a new head gasket on the top of the cylinder.

2. Turn the crankshaft so that the "T" mark on the alternator is in line with the timing index mark on the stator. Install the head while routing the cam chain through the passage in the head. Connect the cam chain with the masterlink; be sure that the open end of the masterlink spring clip is facing the opposite the direction of chain rotation (the cam turns counterclockwise when viewed from the left).



Valve timing index marks. 1, sprocket mark; 2, index mark and "T" mark; 3, crankshaft keyway. When the cam chain is joined, the marks must align as shown

3. Install the sprocket so that the "O" mark is at the top of the sprocket (in line with a line drawn from the crankshaft through the camshaft), when the "T" mark on the rotor is aligned with the timing index mark.



When the "T" mark on the alternator rotor is aligned with the index mark, the "O" mark on the sprocket (2) must align with the mark (1) of the cylinder head

Be sure to install the cam chain masterlink with the closed end facing the direction of chain rotation (125)

4. Install the two cam bolts; note that the two bolts are different types and their installation should not be reversed. It would be a good idea to replace these bolts with new ones and install them with thread locking compound. Torque the cam bolts to 11.5–15 ft lbs.

5. Install the point base. Install the spark advancer locating the slot in the back of the advancer to the pin on the cam; secure the place with a 6 mm bolt. Install the breaker points.

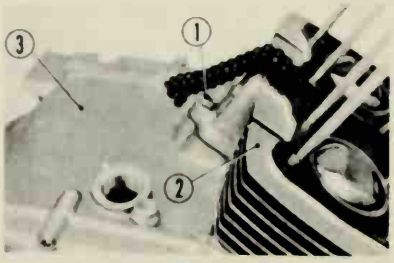
Cylinder head tightening sequence (125)

6. Install the cylinder head cover and the head nuts. Torque the nut in increments of a few ft lbs in the order shown in the accompanying illustration until a torque of 12–15 ft lbs is reached.

7. Adjust the ignition timing, valve tappet clearance, and the cam chain.

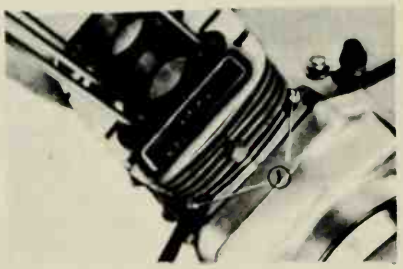
CYLINDER AND PISTON

Removal



1. Remove the cylinder head.

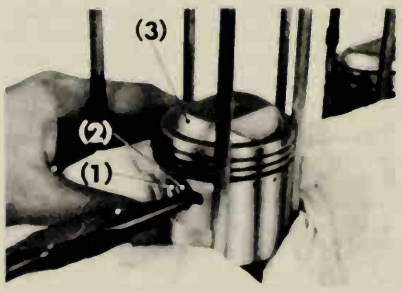
2. Lift off the head gasket. If the head gasket is blown (a piece missing) or shows signs of leakage, inspect the cylinder head closely for warpage in this area.



3. Remove the cylinder hold-down bolt(s) located at the rear of the cylinder, or on the left-side of the cylinder (125).

4. Using the alternator rotor bolt, turn the crankshaft until the pistons are at the top of their strokes. Lift the cylinder up until the bottom of the pistons can be seen at the bottom of the cylinder, then stuff a clean rag around each of the connecting rods. This will prevent the rods from falling against the crankcase when the cylinders are removed and also keep foreign matter from entering the crankcase.

NOTE: *If the cylinder resists removal, tap around the bottom of the cylinder with a plastic mallet. When doing this be careful that the cooling fins are not damaged as will happen if they are struck at an angle. Never attempt to remove the cylinder by prying against the cooling fins.*

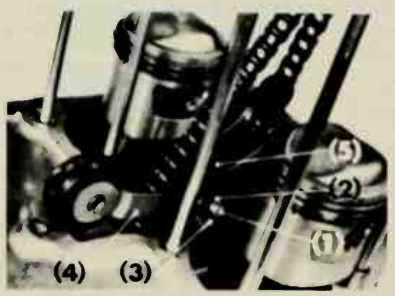


Cylinder bolt (1) (175, 200)

Cylinder bolts (1) (125)

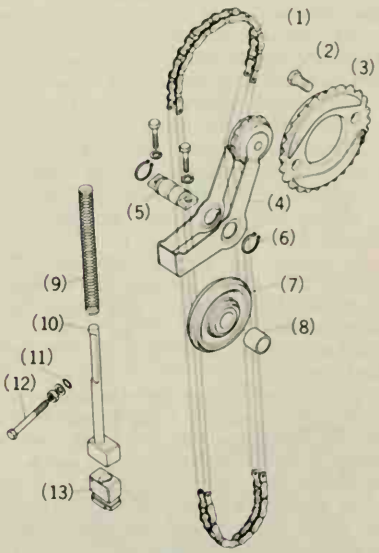
5. With the rag still in place around the connecting rods, remove the wrist pin circlips. The easiest way to remove the circlips is with a pair of needlenose pliers. First rotate the circlip until the opening is near the cutout in the piston. Grasp the circlip near the end-gap and twist in while pulling out. The circlips should never be reused once removed.

6. Push the wrist pin out of the piston by hand if possible. If the pin resists removal, gently head the piston crown with a propane torch and try to push out the pin. Take care when heating the piston not to overheat it; this may distort it. If the pin still resists removal, the factory tool will have to be used. This tool has a band that fits around the piston and a screw device which is screwed in to push out the pin.



Removing the wrist pin circlips

CAUTION: *Never attempt to remove the wrist pin by tapping it out, as the connecting rod or the big end bearing will be damaged in the attempt.*



7. When the wrist pin is removed, the piston can be lifted from the connecting rod. As soon as the piston is removed it should be marked so that it can be installed in the proper cylinder.

8. 175, 200: Remove the two bolts securing the cam chain guide roller to the upper crankcase, and remove the roller assembly. Remove the cylinder base gasket. To remove the pivot pin from the tensioner arm, remove the circlip from either side and slip the pin out.

Inspection

1. The piston and bore specifications in the "Engine Specifications" chart are for standard pistons. Oversize pistons have the oversize stamped on the piston crown. Oversize pistons are available in four oversizes from Honda (0.25, 0.50, 0.75, and 1.0 mm). New pistons come with the wrist pin and rings. If an oversize piston is needed due to a worn bore or worn or damaged pistons, obtain the piston first then have the cylinder bored so that the piston-to-cylinder wall clearance is 0.025–0.050 mm (0.001–0.002 in.).

2. If only piston rings are to be replaced with rings of the same size (standard with standard or oversize with the same oversize), the cylinders must be honed and the ridge at the top of the cyl-

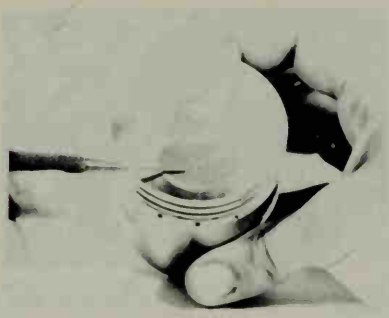
inder removed. The ridge at the top of the cylinder is the upper limit of the top ring's travel. The top ring will wear so that it is mated perfectly with the ridge, however, a new ring will hit the ridge and collapse the piston. Honing the cylinder will aid in seating the new rings.

3. When rings are installed on the pistons, the manufacturer's mark must face *up*; ring end-gaps should be spaced 120° apart around the piston, with no end-gap directly at the front or rear of the piston or directly above the wrist pin.



If a multi-piece oil ring is fitted, position the end gap of the expander 120° from that of the lower compression ring, and the end-gaps of the oil rails 20–30 mm (0.8–1.2 in.) on either side of the expander end-gap.

Installation

1. Install a new wrist pin circlip into the left-side of the right piston and into the right-side of the left piston. If the piston has an arrow stamped on the top, install the piston so that the arrow is pointing to the front of the engine (exhaust side). If the piston has "IN" stamped on the top, install the piston so that the mark is to the rear (intake side) of the engine.

When installing the wrist pin circlips, be sure that the end-gap of the circlip is either at the top or the bottom of the circlip groove and that it is properly seated in the groove.

2. Install the bushing into the cam chain guide roller (200). Hold the guide roller in place in the tensioner arm and slip the pivot pin through the tensioner

The arrow on the piston crown must point toward the front (exhaust side) of the engine

arm and guide roller. Secure the pivot pin in place with the two circlips.

3. Install the tensioner arm assembly between the cylinders with the small roller toward the rear of the engine. Install the two mounting bolts and lockwashers. Torque the bolts to 7–9 ft lbs.

4. Install a new cylinder base gasket and two locating pins to the upper crankcase mating surface.

5. Position the piston on the connecting rod so that the wrist pin holes line up with the connecting rod small end, and install the wrist pin after coating it with oil. Place a cloth under each piston to cover the hole in the crankcase and install the remaining circlip. Be sure that the circlip end-gap is either at the top or bottom of its groove.

6. Pull the cam chain up so that it runs on either side of the tensioner arm pivot pin.

7. Position the pistons at the top of their stroke. If piston bases are available, install them under the pistons, and position the pistons so that they are resting on the base. Coat the piston skirt and rings with clean motor oil; also coat the cylinder walls. Slide the cylinders down over the cylinder studs and pull the cam chain up between the cylinders. If a ring compressor is available, install it on the pistons. If not, have an assistant compress the rings as the cylinders are lowered over the pistons. Make sure that the ring end-gaps are still spaced 120° apart, and that the locating pins are installed in the upper crankcase. Install the cylinder hold-down bolt.
stalled in the upper crankcase. Install the cylinder hold-down bolt.

8. Install the locating pins in the top of the cylinder. Coat the head gasket with a thin coat of oil and position it on the cylinder.

9. Install the cylinder head.

CRANKCASE COVER COMPONENTS

The following sections deal with removal, installation, and inspection procedures for those components located beneath the left and right crankcase covers.

These parts can be serviced with the engine in the frame.

Note the following points:

1. Always drain the oil before removing the right or left front crankcase covers.

2. Any oil seals fitted to the covers (such as kick-starter or gearshift shaft seals) should be carefully checked each time the cover is removed. If the lips of the seal are torn or damaged, or if the seal leaks, remove it by prying it out of the cover with a small screwdriver or hooked tool. Take care not to use the cover itself as a leverage point without protecting it from possible damage.

To install a new seal, press it in with a block of wood which will cover the entire seal. Be sure that the seal is driven straight in until flush with the outer surface of the case, and not cocked to one side. Grease the lips of the seal before inserting any shaft into it. Where the seal must pass over splines on a shaft, ensure that there are no sharp edges from damaged splines which may tear the seal.

3. It is necessary to remove the centrifugal oil filter before the clutch housing can be removed. This requires a special wrench.

Right Crankcase Cover

The right crankcase cover houses the centrifugal oil filter, the clutch, oil pump, external shifter mechanism, and the primary drive.

REMOVAL AND INSTALLATION

1. Remove the oil filler cap and drain the oil.

2. Remove the kick-starter pinch-bolt and pull the kick-starter off its shaft.

3. On CB models, remove the right exhaust pipe.

4. 200 models: Remove the clutch cover and disconnect the clutch cable.

5. Remove the mounting screws and remove the crankcase cover noting the location of any locating pins.

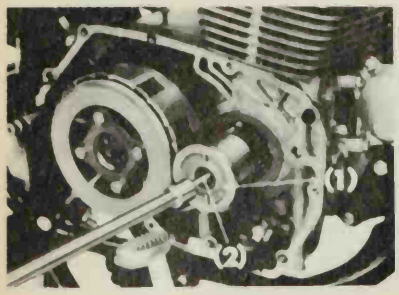
6. Installation is in the reverse order of removal, however, note the following points:

a. Install a new cover gasket;

b. Be sure that the two locating pins are in place between the cover and the crankcase;

c. Inspect the kick-starter shaft seal in the cover. If the lips are torn or damaged the seal should be replaced before installation.

Centrifugal Oil Filter



REMOVAL AND INSTALLATION

1. The oil filter can be removed through the access cover in the right crankcase cover on 125, 175 models. On 200 models, the right crankcase cover must be removed.

2. Remove the screw from the center of the filter cap and pull the cap off the filter housing by screwing an 8 mm bolt into the center, or by using a pliers.

3. Bend back the locktabs from the filter nut in the center of the filter housing. Hold the crankshaft from turning while removing the filter nut with special wrench (Tool No. 07916-2830000). Once the nut is removed the filter housing can be removed from the crankshaft.

4. To install the filter, slide the filter housing onto the end of the crankshaft. Install the tab washer into the filter housing so that the slot in the large tab is

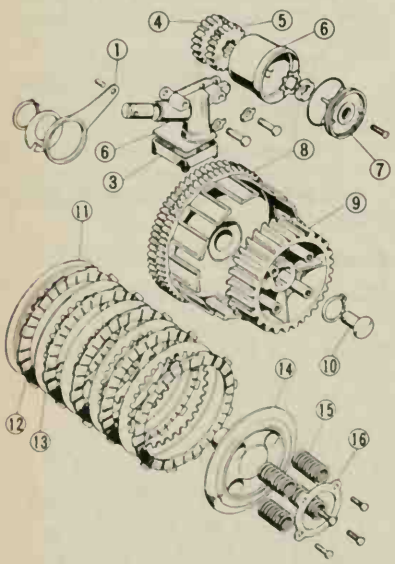
located over a set of splines inside the filter housing. Install the filter nut with the chamfered side toward the engine, and bend the tabs of the tab washer into the slots in the filter nut.

5. Install the filter cap into the filter housing, noting that the vanes on the cap must fit into the splines in the filter housing. Before installing the filter cap, be sure that the O-ring is in place on the cap, and that it is in good condition.

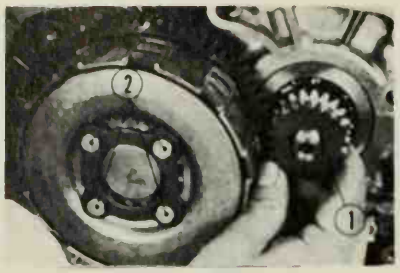
Clutch and Primary Drive



REMOVAL

125, 175

1. Remove the right crankcase cover and the centrifugal oil filter as described previously. Remove the outside primary gear.



2. Remove the four clutch spring bolts. These bolts should be loosened gradually and evenly in an X pattern to avoid distorting the pressure plate. Remove the spring retainer plate, the clutch springs, the pressure plate, and the pressure plate lifter.

3. Remove the friction and steel clutch plates, note that the steel plate at the rear of the hub is a special plate and must be installed first upon assembly. Remove the 20 mm snap-ring from the center of the clutch hub and remove the hub.

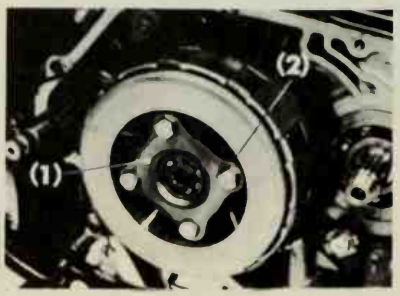
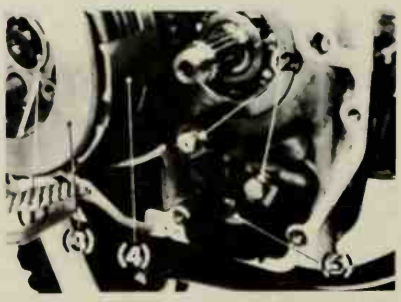
4. Bend back the tabs securing the oil pump mounting bolts, and remove the bolts. The clutch housing and the oil pump assembly can now be removed together.



5. Remove the inside primary gear from the end of the crankshaft. Remove the clutch pushrod from the center of the mainshaft. It may be necessary to apply the clutch lever so that the pushrod will protrude from the mainshaft.

6. Remove the oil pump from the pump rod. Push the pin out of the oil pump piston and remove the piston from the rod. Remove the 26 mm snap-ring from the back of the clutch housing and remove the side washer and the pump rod. Remove the filter screen from the bottom of the oil pump.

200



1. Remove the right crankcase cover and the centrifugal oil filter as previously described. Remove the primary drive gear from the end of the crankshaft.

2. Loosen the four lifter plate bolts gradually and evenly in an X pattern until they are all loose and then remove them. Remove the lifter plate with the lifter piece, and the clutch springs.

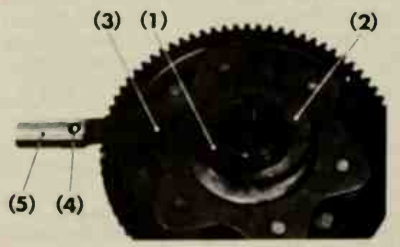
3. Remove the 20 mm snap-ring from the center of the clutch hub, and remove the hub together with the clutch plates and the pressure plate.



To remove the clutch assembly, remove the snap-ring (1) and oil pump bolts (2)

4. To remove the plates from the hub, first lift off the 5 friction plates and the 4 steel plates between them. Remove the 92 mm set ring from the hub and lift off the hub plate, the clutch disc spring, and the clutch disc spring seat.

5. Remove the two bolts securing the oil pump in place, and remove the clutch housing together with the oil pump.

6. Pull the pump from the pump rod. Push the pin out of the oil pump piston and remove the piston. Remove the snap-

ring from the back of the clutch hub, and remove the pump rod side washer, and the pump rod.

INSPECTION

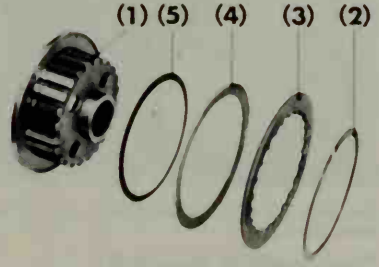
Refer to the specifications charts at the end of this section for clutch dimensions.

Refer to "Lubrication System" for oil pump inspection procedures.

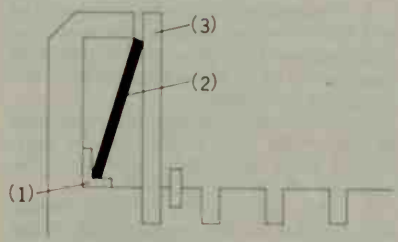
INSTALLATION

125, 175

1. Slip the pushrod into the center of the mainshaft. Be sure that the domed end of the rod is on the clutch side.
2. Install the inside primary gear onto the end of the crankshaft.
3. Install the oil pump connecting rod to the back of the clutch housing, install the side washer. Fit the tab on the side washer into the hole in the clutch housing, and secure in place with the snap-ring. Fit the oil pump piston to the connecting rod and install the piston pin. Oil the piston and insert it into the bore of the oil pump.
4. Install the clutch housing and the oil pump at the same time. Use a new gasket behind the oil pump. Mount the oil pump with the two mounting bolts and bend the side of the lockplates up against the flats on the head of the bolts. Be sure that the lockplates are secured to the oil pump by the large tab on the bottom. Use new lockplates if necessary.
5. Install the clutch hub on the mainshaft and secure with a snap-ring. Install the pushrod and the pressure plate lifter. Install the special steel plate onto the hub first, then install a friction plate, steel plate, and so on until all of the plates are installed. The top plate should be a friction plate.
6. Install the pressure plate, clutch springs, spring retainer plate, and bolts. Tighten the bolts gradually and evenly in an X pattern until they are tight.



When installing the primary gears, line up the punch marks (1)



7. Install the remaining primary drive gear so that the punch mark on the gear is aligned with the punch mark on the inside gear, then install the centrifugal oil filter. When installing the oil filter locknut, be sure that the chamfered side is facing the engine.
8. Install the right crankcase cover.

200

1. Install the clutch pushrod into the center of the mainshaft so that the domed end is facing the clutch.
2. Install the oil pump connecting rod to the back of the clutch housing, install the side washer. Fit the tab on the side washer into the hole in the clutch housing, and secure in place with the snap-ring. Fit the oil pump piston to the connecting rod and install the piston pin. Oil the piston and insert it into the bore of the oil pump.
3. Install the clutch housing and the oil pump at the same time. Use a new gasket behind the oil pump. Mount the oil pump with the two mounting bolts and bend the side of the lockplates up against the flats on the head of the bolts. Be sure that the lockplates are secured to the oil pump by the large tab on the bottom. Use new lockplates if necessary.
4. Install the primary gear onto the end of the crankshaft.

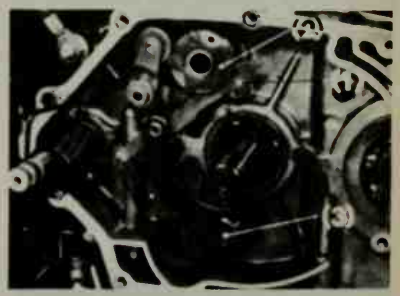
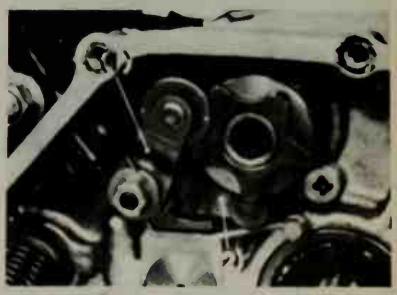
5. Install the clutch disc spring seat, clutch disc spring, the hub steel plate, and the 92 mm set ring onto the hub as shown in the accompanying illustration. Install a friction plate, a steel plate, and so on until all of the plates are in place, the top plate should be a friction plate. Install the pressure plate to the rear of the hub.
6. Install the hub assembly into the clutch housing, and secure it in place with the snap-ring.
7. Install the clutch springs into the hub. Install the spring retainer plate and the bolts. Tighten the bolts gradually and evenly in an X pattern.
8. Install the centrifugal oil filter onto the end of the crankshaft. When installing the oil filter locknut be sure that the chamfered side is facing the engine.
9. Install the right crankcase cover and adjust the clutch.

Shifter Mechanism



REMOVAL

1. Remove the right crankcase cover and the clutch as previously described.
2. Remove the shift lever and the left rear crankcase cover. Remove the circlip from the shifter shaft on the left-side.



Remove the circlip (2) from the shifter shaft (1) to remove the shaft

3. Pull the shift arm down to disengage the fingers from the shift drum and pull the shaft out from the right-side.
4. Remove the nut from the drum stopper stud and remove the drum stopper, drum stopper spring, drum stopper collar, neutral stopper, stopper arm plate, and neutral stopper spring.

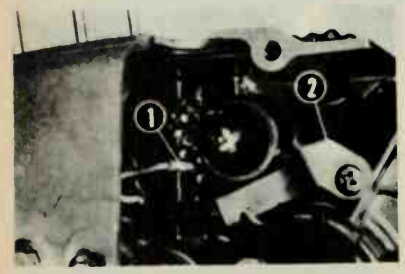
Shift arm (1), shift drum (2), shift shaft (3)

Shift drum stopper (1) and neutral stopper (2)

INSPECTION

1. Check that the drum stopper collar has not been crushed. If this has happened, replace it.
2. Check the splines on the gearshift shaft. If the splines are broken or torn to such an extent that it is difficult to properly secure the shift lever, replace the shaft.
3. Check the shift arm. Be sure that it is not bent. Check that the fingers of the shift arm are not worn or bent.
4. Check the condition of the springs in the shift linkage, especially the shift lever return spring. If any spring has lost its tension, or fails to hold its component properly, it must be replaced.
5. Check that the return spring pin is secure in the case.

INSTALLATION



1. Install the neutral stopper spring, stopper arm plate, neutral stopper, drum stopper collar, drum stopper spring, and the drum stopper onto the drum stopper stud. Install the flat washer and the nut. Check the drum stopper and the neutral stopper are free to move. If not, the nut is too tight or the drum stopper collar is crushed.
2. Coat the shift shaft with a light coat of grease and slip it through the right-side of the engine. As the shaft comes through the left-side of the crankcase, install the snap-ring on the shaft. Ensure that the fingers of the shift arm are in contact with the pins in the shift drum.
3. Refit the clutch and the right crankcase cover. On 200 models, be sure to adjust the clutch before operation.

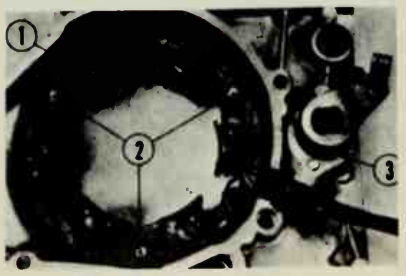
Left Crankcase Cover

The left crankcase cover houses the alternator, starter clutch, neutral switch, countershaft sprocket, and the clutch release mechanism (125, 175).

REMOVAL AND INSTALLATION

1. Remove the pinch-bolt from the shift lever and pull the lever off its shaft.
2. Remove the three mounting screws from the rear cover and remove the cover. Note the location of any locating pins.

Disconnect the neutral switch lead (1) and remove the cable clamp (2)



3. Before removing the front cover, drain the engine oil or remove the battery and tilt the motorcycle at about a 45° angle to the right. Remove the three stator cover mounting screws. Remove the stator cover.
4. Disconnect the alternator wiring from the wiring harness. Disconnect the lead from the neutral switch. Remove the cable clamp from the alternator leads.
5. Remove the mounting screws from the front cover and remove the cover. On 125, 175 models, disconnect the clutch cable from the release mechanism.

NOTE: *On 125, 175 models, be sure not to lose the steel ball from the clutch release mechanism when the cover is removed.*

6. The stator can be removed from the cover once the three mounting screws are removed.
7. To install the covers, attach the stator to the front cover with the three mounting screws. Use a new gasket under the front cover. Be sure to install the two locating pins under each cover.

Drum stopper and neutral stopper components

The stator (1) can be removed by removing the three screws (2)

Countershaft Sprocket

1. Remove the left rear crankcase cover as described previously.
2. To remove the sprocket, remove the two bolts from the sprocket and rotate the lockplate until the tabs on the plate line up with the slots in the countershaft. Remove the lockplate.
3. Either move the rear wheel forward in the swing arm or remove the masterlink from the chain, and pull the sprocket off the countershaft.
4. When refitting the sprocket, install the sprocket on the countershaft. If the masterlink has not been removed, refit the chain to the sprocket before installing the sprocket to the countershaft. Install the lockplate on the countershaft and rotate it until the holes in the sprocket line up with the holes in the lockplate. Install the two bolts and torque to 5.8–8.7 ft lbs.

Alternator and Starter Assembly

REMOVAL

1. Remove the crankcase covers and stator as described previously.
2. Remove the rotor bolt while holding the engine from turning over.
3. Remove the alternator rotor using the factory tool (Tool No. 07933-2160000). The starter clutch is removed with the alternator rotor.
4. Remove the woodruff key from the taper on the crankshaft.
5. The starter clutch can be removed from the back of the rotor after removing the three phillips head screws. Remove the clutch side plate.
6. The starter motor chain can be removed (after removing the sprocket setting plate), by pulling off both sprockets and the chain at the same time.
7. Unbolt the starter motor from the front of the engine, disconnecting the starter motor cable at the motor, and remove the motor tapping the shaft lightly with a plastic mallet if necessary.

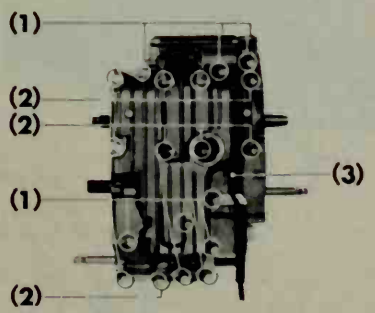
Removing the starter clutch screws from the alternator rotor

INSPECTION

1. For further inspection of the alternator rotor, stator, and starting motor, refer to "Electrical System."
2. Check that the rollers in the starter clutch are free to move. Also check that they all have the same amount of spring tension on them. If any spring feels weak in relation to the others, replace it by removing the roller, spring cap, and spring. Replace the spring and install the cap and roller.
3. Inspect the clutch housing for any cracks. If found defective, it must be replaced.
4. Inspect the surface of the starter sprocket where the rollers contact it. If badly scored, the sprocket and the rollers should be replaced.
5. Inspect the condition of the sprocket teeth. If they are hooked or appear to be worn badly, replace both sprockets and the chain.

Starter clutch components

INSTALLATION



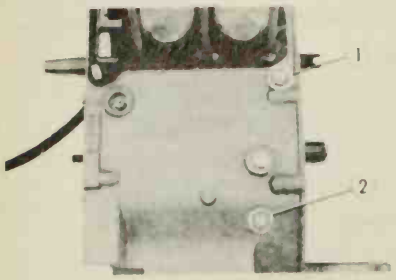
1. Mount the starter motor on the front of the engine with the two mounting screws.
2. Install the starter motor chain and the two sprockets at the same time. Install the starter sprocket setting plate.
3. Mount the starter clutch on the rotor with the three screws. Be sure to install the side plate between the rotor and the clutch.
4. Install the woodruff key in the crankshaft and install the rotor lining up the slot in the rotor with the key in the crankshaft. Draw the rotor down on the crankshaft with the rotor bolt, never strike the rotor as this may affect the magnets.
5. Install the stator in the crankcase cover, then install the cover using a new gasket. Check that the rotor does not come in contact with the stator as the engine turns over. Install the stator cover and the rear cover.

CRANKCASE COMPONENTS

To service the kick-starter, transmission, or the crankshaft, the crankcases will have to be separated. To service the kick-starter and transmission, the left and right crankcase covers and the components beneath them will have to be removed. Service to the crankshaft also necessitates the disassembly of the top end as the cam chain must be removed with the crankshaft (200) or disconnected (125, 175).

Splitting the Crankcases

1. Remove the engine from the frame.
2. If the crankshaft is to be serviced, disassemble the top end as outlined previously.
3. Remove the right and left crankcase covers and the components beneath them.



Lower crankcase bolts: 1, 6 mm; 2, 8 mm; 3, starter motor cable

NOTE: *Loosen the oil filter nut and the rotor bolt before removing the clutch.*

4. Turn the engine upside down and remove the nine 6 mm bolts and nine 8 mm bolts from the lower crankcase. One of these bolts can be reached through the drain plug opening. Remove any mounting bolts from the upper crankcase. Remove the lower crankcase half, tapping around the mating surface with a plastic mallet to free the case half if stuck. The crankshaft and the transmission will remain in the upper half.

Kick-Starter

REMOVAL

1. Split the crankcases as described previously.
2. Remove the return spring from the kick-starter shaft on the outside of the lower crankcase.
3. Remove the circlip from the inside of the shaft and remove the components from the shaft. Slip the shaft out of the case.

INSPECTION

1. Inspect the splines on the end of the kick-starter shaft. If they are damaged to the extent that the kick-starter lever cannot be properly fastened, the kick-starter shaft should be replaced.
2. Check the condition of all circlips. Replace any which are distorted.
3. Inspect the condition of the springs, replacing any which are weak or broken.

The friction spring should be seated properly in the gear

4. Check that the kick gear rotates freely on the shaft gear. If the gear binds, it should be repaired or replaced.

INSTALLATION

1. Install the shaft into the lower crankcase half. Install the components on the shaft as shown in the accompanying illustration. Hold the shaft so that the

2. Remove the neutral switch rotor and the drum stopper from the shift drum. Remove the bearing set plate from the right side of the upper crankcase. Remove the guide pin clips and the guide pins from the shift forks. Mark the location of each shift fork (left, center, and right; or, left and right on four-speed transmissions), and slide the shift drum out of the case from the right-side.

3. The transmission gears can be removed from their shafts after removing the circlips which secure them. All components should be carefully laid out in the order in which they are removed so that they can be installed in their proper locations.

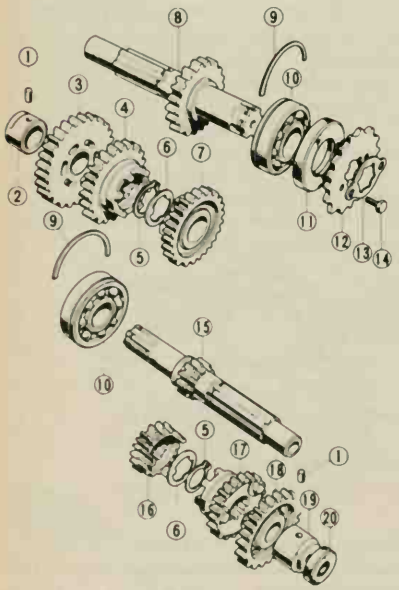
Remove the shift drum (1) and shift forks



INSTALLATION

1. Slip the shift drum into the upper crankcase; as the drum enters the case, install the shift forks. Be sure that the forks are installed in the same position from which they were removed. Install the neutral switch to the end of the shift drum.

2. Install the bearing set plate and the neutral stopper and drum stopper. Position the shift drum in the neutral position as seen by the neutral switch.

3. Assemble the mainshaft and the countershaft. Install the transmission shafts in the upper case. Be sure that the shift forks are fitted to the proper gears. Be sure that the bearings are fitted to the set ring or the locating pins. When properly fitted the bearings should sit flush in the case.

4. The remainder of assembly is in the reverse order of removal.

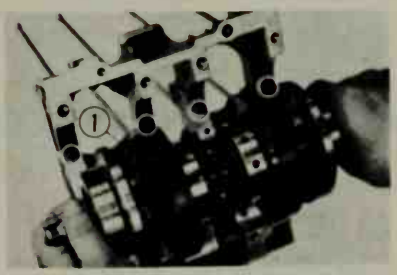
Crankshaft

REMOVAL

1. Remove the top end and split the cases as described previously.
2. The crankshaft can be lifted out of the upper crankcase. On 200 models, the cam chain is removed with the crankshaft

CAUTION: *Do no lose the main bearing locating pins when the crankshaft is removed.*



INSPECTION

1. Mount the crankshaft center main bearings in a set of V-blocks, and measure the run-out of the crankshaft with a dial gauge. Measurements should be taken at either end of the crankshaft and on each of the flywheels. If the run-out exceeds the service limit, the crankshaft should be replaced.

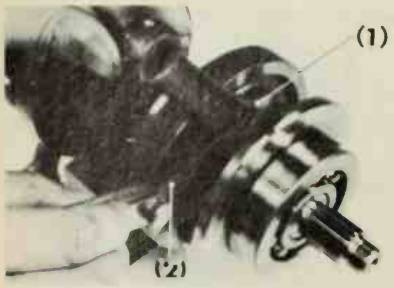
Removing the crankshaft. Note bearing locating pins.

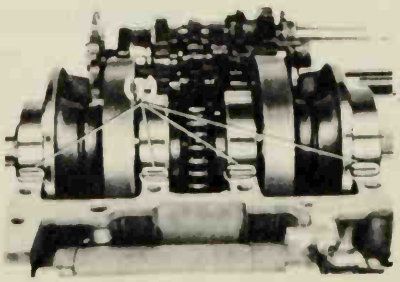
Measuring crankshaft run-out

Transmission (5-speed)



2. With the crankshaft supported at both ends, mount a dial gauge to the top of each main bearing in turn. Attempt to move the outer race up and down. The measurement on the dial gauge is the total radial clearance. If the clearance exceeds the service limit, the crankshaft should be replaced.

3. With the crankshaft firmly supported, fix a dial gauge to the bottom of the connecting rod, and measure the up and down play. The dial gauge will indicate the amount of radial clearance. If the clearance exceeds the service limit, the crankshaft should be replaced.



4. Using a feeler gauge, measure the side clearance of the connecting rod. If the side clearance is beyond the service limit, replace the crankshaft.

5. With an inside micrometer, measure the bore of the connecting rod small end. If the bore is found to exceed the service limit, the connecting rod and the crankshaft should be replaced.

6. Rotate each of the main bearings. They should be smooth and silent. If rough or noisy, they should be replaced.

Measuring connecting rod side clearance

The aligning marks on the crank bearings should be flush with the crankcase surface so that the locating pins will fit properly into the bearings

① Unless otherwise specified

INSTALLATION

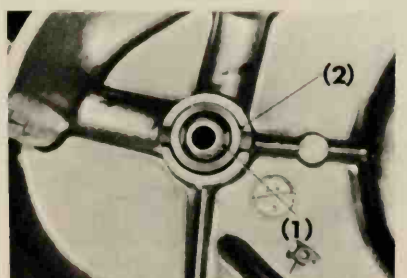
1. Fit the cam chain to the sprocket on the crankshaft.
2. Fit the crankshaft into place. Be sure that the bearing locating pins are properly seated in the upper crankcase half. The aligning marks on the bearing should be flush with the crankcase mating surface.
3. Assemble the crankcases and the top end.

Assembling the Crankcases

1. The crankcase mating surface must be clean and free of any scratches. Minor repairs can be made with an oilstone.
2. Apply a thin coat of sealing compound to the crankcase mating surface. Be careful not to get any of the sealer on the bearings or inside surface of the crankcase.
3. Install the lower case. Make sure that the cases mate properly before installing the crankcase bolts. If they do not, check that all of the bearing locating pins are in place.
4. Install the crankcase bolts and tighten them evenly and gradually in an "X" pattern, starting from the inside and working out.
5. Install the crankcase cover components and the top end as described previously.

LUBRICATION SYSTEM

These Honda twins are of the wet sump type. All models have a plunger-type pump driven from the clutch housing by way of a connecting rod. Before entering the pump, the oil passes through an oil filter screen to remove any large particles. Before being pumped to the cylinder head, the oil is further filtered through a centrifugal oil filter before being pumped under pressure to the crankshaft assembly and the transmission shafts.



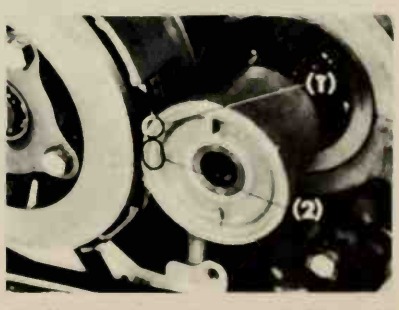
CENTRIFUGAL OIL FILTER

Removal

1. Remove the right crankcase cover.
2. Remove the 6 mm screw from the center of the filter cap. Screw an 8 mm screw into the cap and pull the cap out of the housing using the screw, or remove it with a pliers.
3. Hold the crankshaft from turning by either placing the transmission in gear and applying the rear brake or by wedging a soft (copper or brass) bar between the primary gears. Bend back the locktabs on the tabbed washer and remove the special 16 mm locknut using the factory tool (Tool No. 07961-2830000). Remove the tabbed washer and the filter housing.

Inspection

1. Clean all parts in a clean solvent and allow to dry.
2. Inspect the condition of the filter capscrew. If the head is rounded or if the threads are stripped, it should be replaced.
3. Inspect the filter cap O-ring. If it is deformed, torn, or cracked, it must be replaced.
4. Check the condition of the tabs on the tabbed washer. If they are weak or missing, the washer must be replaced.
5. Check the 16 mm locknut for condition. If the slots on the outside of the nut are badly damaged or the threads are chipped or stripped, the nut should be replaced.



To remove the oil guide from the side cover, line up the slot in the retaining circlip (1) with the tab in the inside of the guide (2)

6. Inspect the oil guide in the right crankcase cover (200) or in the filter cover plate (125, 175). It should be free to move in and out. Push the guide in, it should have enough spring force behind it to push it out. To remove the guide, line up the opening on the retaining circlip with the tab on the guide, the guide can now be pulled from its housing and the spring behind it removed. Replace any damaged parts.

Installation

1. Install the filter housing on the crankshaft, then install the tabbed washer. The large tab on the washer must fit over one of the set of splines in the inside of the housing. Install the locknut

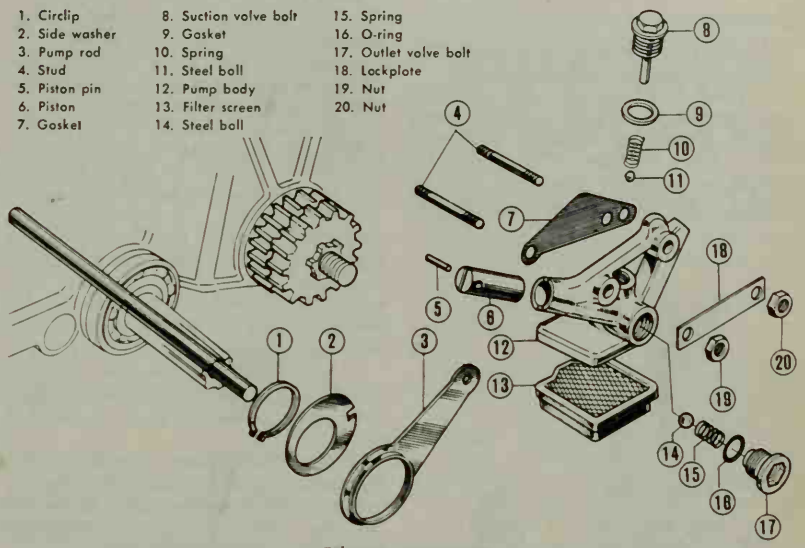
On 200 models, line up the tab on the filter cap (2) with the mark on the filter housing (1)

with the chamfered side facing the engine, and tighten with the factory tool (Tool No. 07961-2830000).

2. Install the filter cap using a new O-ring if necessary, and secure in place with a 6 x 20 mm screw. The vanes on the filter cap must fit into the splines in the filter housing. On 200 models, the tab on the cap must align with the mark on the housing.

OIL PUMP AND FILTER SCREEN

The oil pump and filter screen are removed and installed with the clutch housing. Refer to "Engine and Transmission."



Inspection

1. Calculate the clearance between the oil pump connecting rod and the clutch housing. The standard clearance is 0.001–0.003 in. (0.025–0.075 mm). If the clearance exceeds 0.006 in. (0.15 mm), replace parts as necessary to bring the clearance to the standard specification.

2. Calculate the clearance between the pump piston and the pump bore. The standard clearance is 0.001–0.0025 in. (0.025–0.063 mm). If the clearance exceeds 0.007 in. (0.17 mm), the pump assembly (pump, piston, and rod) should be replaced as a unit.

3. Make a visual inspection of the piston and bore in the oil pump. If either is scored, replace the pump as an assembly.

4. 125, 175 models: On most models the ball valves can be removed for inspection by removing the valve cap, washer, spring, and ball. Inspect the ball for any signs of wear. If the ball is worn, replace the pump as an assembly.

Oil pump components

5. 200 models: The pump operation can be checked after assembly. Start the engine and allow it to warm up until it will idle with the choke off. Loosen the left rear head capnut; if the pump is operating properly, oil should begin to seep out the gasket surface. After checking operation, torque the head nut to 13–16 ft lbs.

6. Remove the filter screen from the bottom of the pump and wash in clean solvent. Inspect the screen for any puncture marks. If the screen mesh is broken to any extent, the screen must be replaced.

7. Check the oil pump gasket for condition. If defective in any way, it must be replaced. It is recommended that the gasket be replaced regardless of apparent condition.

8. Inspect the condition of the mounting bolt or nut lockplate and replace it if the tabs are fatigued.

FUEL SYSTEM

CARBURETOR

Removal and Installation

1. Unscrew the carburetor cap and pull the throttle slide assembly out of the carburetor. If the slide assembly is to be disassembled, see the procedure below. If not, place a small plastic bag around the assembly to keep out dirt, and place it out of the way. Note that mishandling the assembly may necessitate replacement of the slide or needle.

2. Check that the fuel petcock is shut off, and disconnect the fuel line from the carburetor.

3. Remove the float bowl drain plug, and drain off any gas in the float bowl. Disconnect any overflow or breather tubes.

4. Loosen the carburetor or the manifold mounting nuts or bolts, then remove them.

5. Loosen the air cleaner hose clamp or band. Remove the carburetor.

6. Installation is in the reverse of the above, but note the following points:

a. Be sure that the carburetor mounting flange O-ring is installed in its groove before fitting the carburetor.

b. When tightening the carburetor or manifold flange nuts, do so evenly to prevent warpage.

c. Lubricate the throttle slide if desired with a molybdenum or graphite lubricant. Insert it into the carburetor with the slide cutaway facing away from the engine. Be sure that the slot in the slide is engaged with the tab in the carburetor body;

d. Be sure that the slide goes in easily, and especially that the needle enters the needle jet. Do not push or force the slide into place. If resistance is noted, it is probable that the needle is cocked to one side and is not entering the jet;

e. Tighten the carburetor cap and check throttle operation. The slide must move freely up and down.

Disassembly

1. If disassembly of the throttle slide components is desired, compress the return spring against the carburetor cap, disengage the cable from the slide, take out the spring clip, needle, and needle clip. If the clip must be removed from the needle, note which groove it is located in so that it can be installed in the same location unless tuning changes are to be made.

2. Flip up the retainer on the float bowl and separate the float bowl from the carburetor body. Do so carefully, to avoid damage to the floats. Remove and discard the float bowl gasket.

NOTE: *If the float bowl is stuck, tap carefully with a plastic mallet to break the seal.*

3. Push out the float pivot pin with a small dowel, and take out the floats. Remove the float needle from its seat. Unscrew the seat itself.

4. Unscrew the main jet.

5. Unscrew the jet holder and push the needle jet out from the top of the carburetor using a small wooden dowel.

6. Unscrew and remove the pilot jet.

7. Remove the pilot air and throttle stop screws and springs.

Assembly

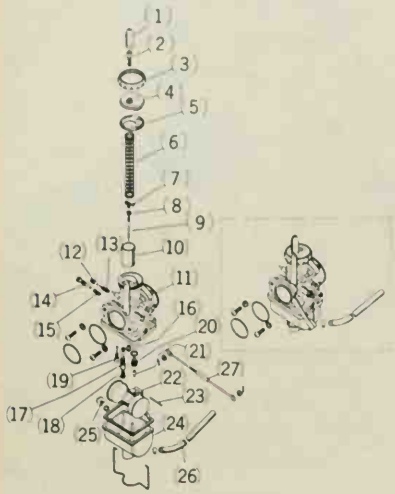
Assembly is basically the reverse of the above, but note the following points:

1. Float bowl gaskets and manifold and needle jet O-rings (where fitted) should always be replaced with new ones. Other O-rings or fiber gaskets should be carefully inspected and replaced if less than perfect in condition. Check O-rings for tears or cracks; fiber gaskets for crushed condition.

2. Exercise care when installing jets. Install the needle jet, jet holder, main jet, pilot jet, and float needle seat.

Some models have an O-ring on the needle jet which must be in place.

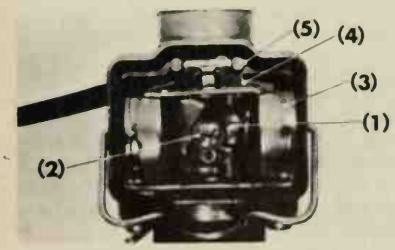
CAUTION: *Do not overtighten the jets as they are made of soft brass which is easily damaged.*



3. Install the float needle into its seat. Hold the floats in place and install the pivot pin.

4. Assemble the throttle slide so that the cutaway on the throttle slide is facing the air cleaner.

5. Install the pilot air screw, turning it in until lightly seated, then backing it out the proper number of turns as listed in the chart.



6. After completing assembly, install the carburetor on its manifold. If the carburetor bolts to the manifold, make sure that the bolts or nuts are tightened evenly, but not overtightened.

7. Check for fuel or air leaks; make final adjustments to the throttle stop and pilot air screws.

FUEL PETCOCK AND LINES

Cleaning

1. Unscrew and remove the sediment bowl, take out the O-ring, and filter screen.

2. Clean the metal parts in solvent. Check that the filter screen is not punctured, and that the O-ring is not torn or otherwise damaged.

3. Run a little gas through the petcock to flush out any dirt. Catch the gas in a suitable container. Turning the petcock to "Reserve" for a few seconds should remove the better part of any water or dirt in the bottom of the fuel tank.

4. Check petcock operation in all postitions. There must be no fuel flow when the petcock lever is turned to the "Stop" position.

5. Install the filter screen, O-ring, and sediment bowl in that order. Check for leaks before operating the motorcycle.

Disassembly

At somewhat extended intervals, the petcock should be removed from the fuel tank and cleaned.

1. Drain the fuel tank completely. Disconnect the fuel lines from the petcock. Remove the sediment bowl, O-ring, and filter screen.

2. Unscrew the nut which holds the petcock to the fuel tank (200 models), or remove the phillips head screw from the inside of the petcock above the filter screen (125, 175), and remove the petcock.

3. Remove the two screws from the fuel lever setting plate, and remove the setting plate, lever spring, lever, and gasket.

Assembly

1. Install the fuel valve gasket, lever, lever spring, and setting plate. Secure with the two screws.

2. Be sure that the petcock O-ring or gasket is in place and install the petcock on the fuel tank. Install the sediment bowl filter screen, O-ring, and sediment bowl.

3. Be sure that the fuel lines are firmly secured at their connections and the safety circlips are in place.

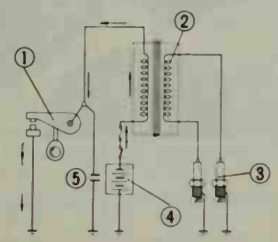
ELECTRICAL SYSTEM

The same basic type of electrical system is used on all models covered in this manual.

Ignition is by means of battery-and-coil, the battery also being used to power the lights and accessories.



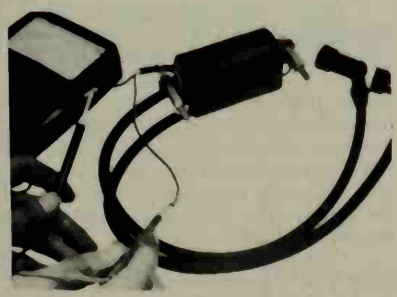
Battery charging is accomplished by means of an alternator with a permanently-magnetized rotor. Alternator output (AC) is changed to direct current (DC) by the rectifier and this current charges the battery. On late model 175s and the 200, a voltage regulator is fitted to ground excess alternator output.

IGNITION CIRCUIT TESTS

The ignition circuit consists of the battery, a set of breaker points, condenser, ignition coil, spark plug leads and caps, and the spark plugs.

One set of points is used along with a single ignition coil. Both plugs fire at the same time, although only one cylinder is on the compression stroke at a time. Therefore, there is a waste spark at one cylinder each time the engine fires.

The contact breaker set is mounted on a plate and is opened and closed by a breaker cam on the left-side of the camshaft. The ignition coil and condenser are mounted beneath the gas tank.



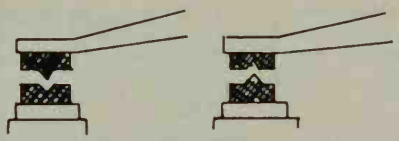
Ignition circuit: 1, breaker points; 2, coil; 3, spark plugs; 4, battery; 5, condensers

1. Noise suppressor spark plug caps are fitted, which are designed to eliminate radio interference and provide a hotter spark by means of a resistor in the cap.

Sometimes the resistor breaks down, and the cap then becomes an open circuit. Remove the cap from the plug lead, and hold the lead about ⅛ in. away from the cylinder head, while kicking over the engine. If a good spark is now evident, the cap was at fault. Replace both caps if one was defective.

2. If new points have just been installed, a no-spark condition can be caused by improperly installed or damaged insulating washers on the points primary wire terminal.

3. The ignition coil windings should be checked for continuity, using an ohmmeter.



Checking the ignition coil primary winding for continuity

a. Disconnect the two low-tension coil leads and check for continuity between them. This is a check of the primary winding. If there is no continuity, replace the coil since the winding is broken internally;

b. Check for continuity across the two high tension (spark plug) leads. Resistance should be very high, but continuity must exist. If resistance is low or infinite, the secondary winding insulation is breaking down or the winding is broken. The coil must be replaced in either case.

If the condition of the coil is still questionable, replacing it temporarily with one known to be good is recommended.

4. The condenser can be checked if a capacitance tester is available. Condensers should have a capacitance of approximately 0.3 mf. Checking with a "megger" (high-voltage ohmmeter) should yield a resistance of 10m ohms or better at 1,000v. Replace the condenser if it fails either test.

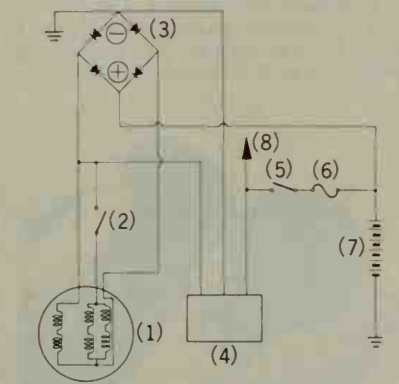
A defective condenser will cause mounds and matching depressions on the point contact surfaces

NOTE: *After testing, ground the condenser lead against the case to discharge it.*

As noted above, sparking at the points, or points which pit or burn rapidly would indicate a defective condenser. Bad condensers will cause mounds and matching depressions on the points, as illustrated.

5. If the trouble is a misfire, and the tests above do not pinpoint the problem, check the condition and operation of the automatic timing advance unit.

CHARGING CIRCUIT TESTS



The charging circuit consists of the alternator, rectifier, a voltage regulator (where applicable), and the battery.

1. In the event that the battery overcharges, check the battery itself, and the voltage regulator.

2. If the battery discharges quickly, or fails to hold a charge, check the battery, the regulator, rectifier, and alternator.

Voltage Regulator

A bad voltage regulator may cause the battery to go dead, or may overcharge it causing electrolyte loss, short light bulb life, etc. The regulator is located beneath the battery box, and is rubber mounted. It can be tested with an ohmmeter, continuity tester, or ammeter.

Charging circuit: 1, alternator; 2, headlight switch; 3, rectifier; 4, voltage regulator; 5, main switch; 6, fuse; 7, battery; 8, load

1. If the battery goes dead, disconnect the three regulator leads (yellow, green, and black).

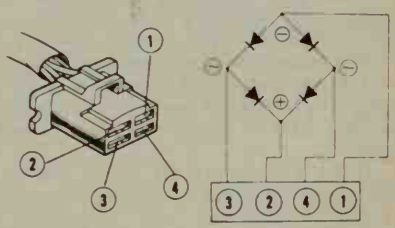
2. With an ohmmeter or continuity light, check for continuity between the yellow lead and the green lead. Check for continuity between the yellow lead and ground.

There must not be continuity in either case. If there is, the regulator must be replaced.

3. If an ammeter is available, connect it in series with the battery positive wire. Start and run the engine at more than 2,000 rpm. If the ammeter indicates that the battery is discharging, disconnect the regulator yellow lead and repeat the test. If the battery now shows that it is receiving a charge, the regulator must be replaced. If no change is noted, proceed with the rectifier and alternator tests which follow.

4. If the battery overcharges, check as follows:

Assuming that the battery is in good condition and *fully* charged, start the engine and connect a good voltmeter across the battery terminals. Run the engine at 4,000 rpm. The voltage across the battery should increase to between 14–15 volts, but not more. If the meter reads more than 15 volts, the regulator must be replaced.



NOTE: *This test will not be valid unless the battery is fully charged. To check this, run the engine until the voltage stabilizes, then disconnect the regulator black lead. If the voltage increases, the results of the test were valid.*

5. When mounting the regulator, be sure that the rubber dampers are in place. The regulator could be damaged by excess vibration.

Rectifier

The rectifier is located behind that battery or under the battery case.

The rectifier should be checked in the event of insufficient battery charging. Tests can be carried out with a continuity light or a standard (low-voltage) ohmmeter.

Rectifier leads: 1, green; 2, red/white; 3, yellow; 4, pink

CAUTION: *Do not apply high-voltage to the rectifier.*

1. Disconnect the leads and remove the rectifier from the machine.

2. The test involves testing current flow through the rectifier in both directions. The rectifier consists of four

diodes. When in working condition, a diode will pass current in one direction only.

If the diode passes current in both directions, or in neither direction, it is defective. If any of the diodes are defective, the rectifier must be replaced.

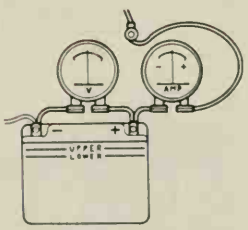
3. Connect the negative lead of the tester to the green wire, and the positive lead to the yellow, red/white, and pink wires in turn.

In each case, note whether or not there is continuity.

NOTE: *On an ohmmeter, "continuity" will be indicated by a resistance of 5–40 ohms. "No continuity" by a resistance of 100 or more ohms.*

4. Now reverse the tester connections, connecting the positive tester lead to the green wire, and the negative to each of the others in turn.

In every case, the reaction of the tester must be the opposite of the first test: i.e., if the first test showed continuity between two leads, reversing the tester connections must show no continuity.



Current flow in both, or in neither, directions for any two leads indicates that the rectifier is defective and must be replaced.

Alternator

The alternator should be checked in the event of low or no battery charging not attributable to the other components.

1. A dynamic output test can be carried out if a voltmeter and ammeter are available. The battery *must* be fully charged or the test may be invalid.

Hook up the voltmeter across the battery terminals, disconnect the battery red/white lead and connect it to the ammeter. Connect the other side of the ammeter to the battery positive terminal.

Checking alternator output

Disconnect the black regulator lead.

Start the engine and compare the voltmeter and ammeter readings with lights off and lights on (high-beam) at the given rpm.

If the readings are not within 10% of the given specifications, the alternator should be replaced.

NOTE: *The alternator should not be excessively hot when this test is carried out.*

2. Using an ohmmeter or continuity tester, a static stator test can be carried out.

Disconnect the alternator wiring at the plastic connector.

3. Check for continuity between the white, the yellow, and the pink leads. Continuity must exist, or the stator assembly has a broken wire and it must be replaced.

4. Check for continuity between the yellow lead and the stator core. If continuity exists, there is a short, and the stator must be replaced.

5. Check for cracked or melted insulation or scored or burned coil core ends.

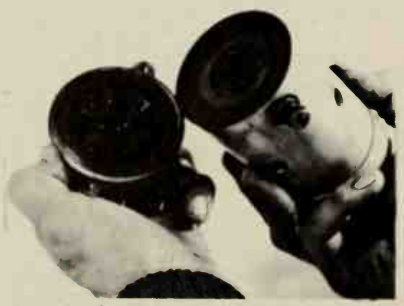
STARTER MOTOR

1. If the starter motor spins when the button is pushed, but the engine does not, the starter clutch is defective. Refer to "Engine and Transmission," for starter clutch removal and inspection procedures.

2. If the warning lights dim when the starter button is pushed, but the engine and starter do not turn over, the battery may be too low, or the starter may be defective.

3. If nothing happens when the starter button is pushed, either the starter solenoid is defective, or there is a loose wire in the electric starter circuit.



Removal and Disassembly

1. Disconnect the lead at the starter motor.

2. Remove the alternator cover, both sections of the left crankcase cover, and disconnect the neutral switch lead.

3. Remove the alternator rotor.

4. Remove the starter sprocket setting plate (secured by a phillips screw), and remove the two sprockets and chain together.

Removing the output side end plate

5. Remove the two screws which secure the starter motor, and tap the starter out of the case.

6. To disassemble the starter, remove the two long phillips screws and remove the end plates.

NOTE: *Exercise caution when removing the output side end plate as this contains the reduction gears.*

7. Disconnect the starter carbon brush leads (2) and remove the brush mounting plate.

Removing the brush side end plate

Disassembly past this point is not necessary.

Inspection

1. Use an ohmmeter or continuity tester to check the starter motor.

2. Check for continuity between each of the commutator segments. There must be continuity between all of them. If there is a dead spot, the starter must be replaced.

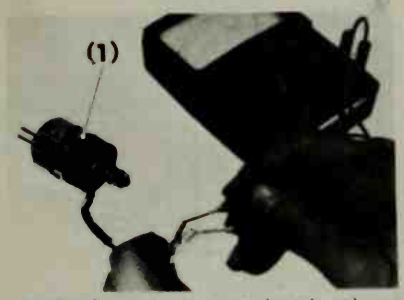
3. Check for continuity between the armature core and the commutator; there must be none. If continuity exists, the starter must be replaced.

4. Check for continuity between the starter lead terminal and the brush leads. Continuity must exist or the starter must be replaced.

5. Measure the length of each carbon brush. Replace them if either is less than 5 mm (0.2 in.). Standard (new) brush length is 11.0–12.5 mm (0.4–0.5 in.). Replace any brush which is pitted or cracked.

6. Clean the commutator surface thoroughly with a solvent. Check that there is no scoring on the commutator surface. The mica insulation should undercut the commutator segments by at least 0.3 mm (0.012 in.). If less than this, the mica should be undercut using a piece of a hacksaw blade or the like. Be sure to clean the commutator surface thoroughly after this operation. Remove any sharp edges.

7. Check the brush springs and replace them if deformed or if they will not hold the brush firmly against the commutator.



Assembly and Installation

1. Reverse the above procedures. Be sure that the output side O-rings are in place.

2. After assembling the starter, check that the armature will turn without excessive binding.

Starter Solenoid

1. The starter solenoid can be checked by disconnecting the high-tension lead from the starter motor, and pushing the starter button. The solenoid should click when the button is pushed.

Checking for continuity across the solenoid primary leads

2. If it does not, use an ohmmeter or continuity light to check for continuity across the solenoid's primary leads (black and yellow/red). If continuity does not exist, replace the solenoid.

3. Connect a fully charged 12-volt battery to the primary leads, then check for continuity across the high-tension leads. If there is no continuity, replace the solenoid.

ELECTRICAL SWITCHES

All electrical switches are easily checked with an ohmmeter or self-powered continuity light after disconnecting the switch leads at the plastic connectors.

NOTE: *Wire color codes may differ on some older models.*

Ignition Switch

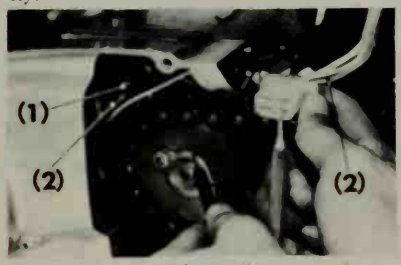
1. With the key turned to the first position, check for continuity between the black and red leads. If continuity does not exist, replace the switch.

2. With the key in the first position, continuity must exist between the brown and the brown/white leads.

3. With the key in the second position, continuity must exist between the red and brown leads.

Brake Light Switches

1. Check for continuity across the front brake light switch terminals (black and green/yellow). Continuity should occur when the brake lever has moved 10–20 mm (0.4–0.8 in.), measured at the tip of the lever.



2. Check for continuity between the black and green/yellow leads to check the rear brake light switch. Continuity should occur when the brake pedal has moved about 25 mm (1 in.). This switch is adjustable.

Kill Button

1. The kill button should show no continuity between the black and the black/white leads when in either "off" position. When in the "run" position, there must be continuity.

Neutral Switch

1. Remove the left crankcase cover. With the transmission in Neutral, check for continuity between the switch and the crankcase. There should be continuity.

Checking neutral switch operation

2. When the transmission is in gear, there should be no continuity.

Horn

1. If the horn will not function, connect a 12-volt battery directly to the horn terminals. If the horn does not sound, it is defective.

2. If the horn does sound, check the horn button by disconnecting the light green lead in the headlight and check for continuity between the lead and ground, which should be present when the horn button is pushed.

Headlight Switch

EXCEPT 200T

1. When the switch is "off," there should be no continuity between the leads except the brown/white and white leads on 200 cc models.

2. When the switch is in the high-beam position (H), there should be continuity between the yellow/white and the yellow leads, and between the black, blue, and brown/white leads.

3. When the switch is in the low-beam position (L), there must be continuity between the yellow/white and yellow leads, and between the black, white, and brown/white leads.

200T

There is no headlight switch; the dimmer switch is fitted to the left handlebar.

To check the dimmer: in the "Lo" position, continuity should exist between the white and black/white leads. In the "Hi" position, continuity should exist between the black/white and black leads.

Turn Signal Switch

1. When the left-hand turn signal is activated, there will be continuity between the gray lead and the orange lead.

2. When the right-hand switch is activated, continuity will exist between the gray lead and the light blue lead.

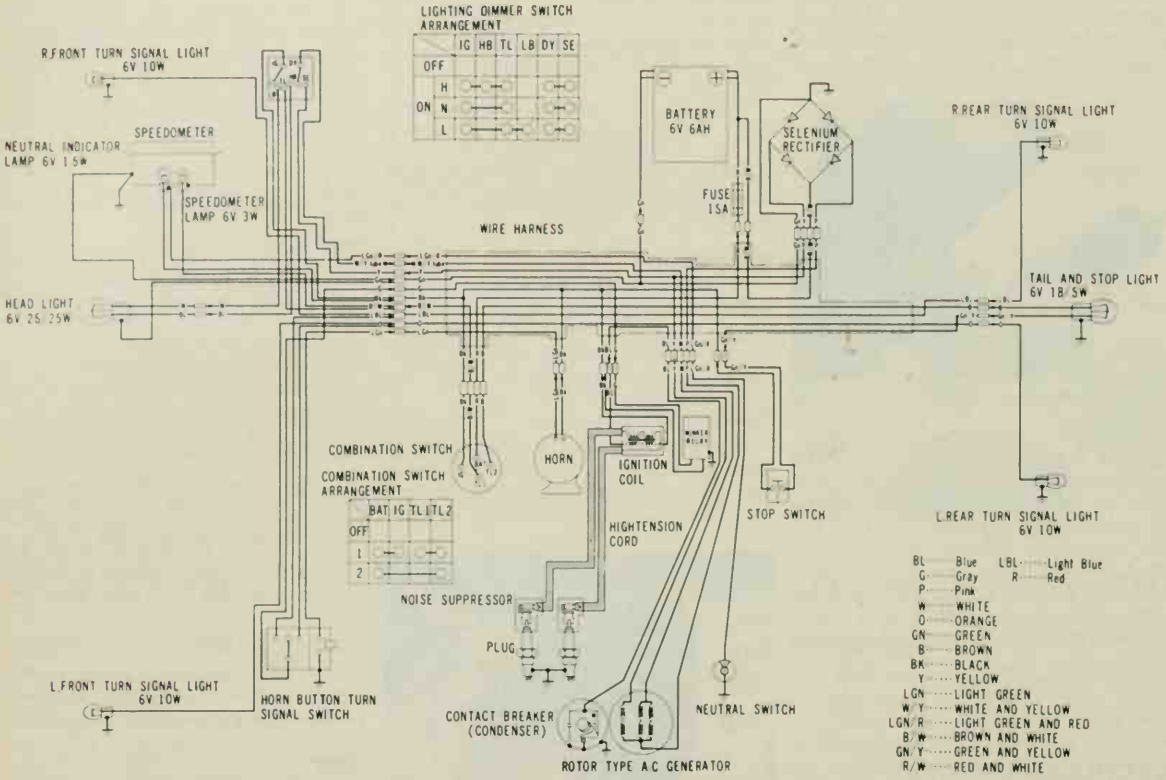
Starter Button

1. If nothing happens when the starter button is pushed, and the solenoid seems correct, check the starter button.

200T

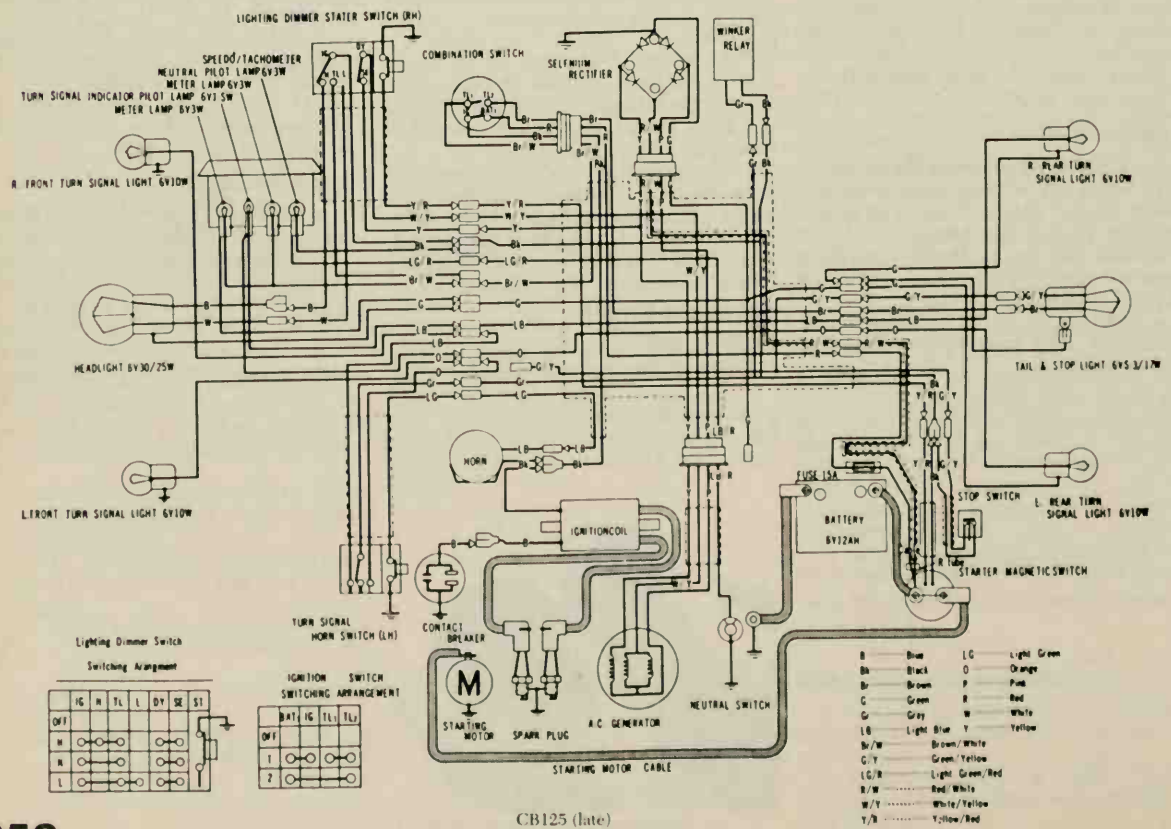
a. Disconnect the starter button leads. When the button is free, continuity should exist between the black and black/white leads;

b. When the button is depressed, continuity should exist between the black and yellow/red leads.



NOTE: *The starter button shuts off the headlight when the starter button is pushed.*

OTHER MODELS



a. Disconnect the yellow/red starter button lead. Check for continuity between the yellow/red switch lead and ground. Continuity should exist only when the starter button is pushed.

NOTE: *After separating the starter button housing, spray the button contacts with electrical connector cleaner.*

CHASSIS

WHEELS, BRAKES

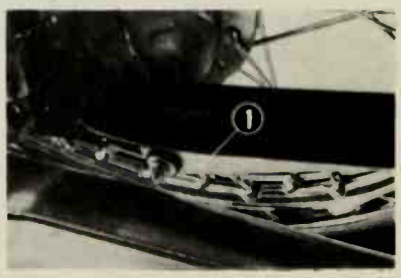
Front Wheel Removal and Installation

DRUM BRAKE

1. Remove the phillips head screw securing the speedometer cable to the brake plate and disconnect the cable.
2. Loosen the locknut on the front brake cable adjuster at the handlebar lever, and screw the adjuster into the lever housing to increase the amount of slack in the cable. Remove the cotter pin from the front brake arm, pull the arm back by hand, and disconnect the cable. Unscrew the locknut on the lower cable adjuster (on the brake plate), until it is removed from the adjuster. Remove the cable and adjuster from the brake plate.
3. Bend back the tabs on the lockplate securing the brake anchor bolt (on the brake plate), and remove the bolt.
4. Remove the cotter pin from the axle nut and loosen the axle nut a turn or two. Support the front wheel off the ground by placing the motorcycle on the center stand and installing a support under the engine. Remove the axle nut, and pull the axle out using a phillips head screwdriver or similar tool inserted through the hole in the axle.
5. Remove the front wheel and remove the side collar from the left-side of the hub and place it and the axle nut on the axle for safekeeping.
6. Refer to the following wheel component service sections if necessary.
7. To install the wheel, insert the side collar into the oil seal on the left-side of the hub, apply some grease to the lips of the oil seal before installing the side collar. Hold the wheel in place between the forks and slip the axle into place, after coating it lightly with light grease. Connect the speedometer cable while rotating the wheel slowly, secure the cable with the set screw. Install the brake anchor bolt. Be sure that the tabs on the lockplate are in good condition and bend the tabs up against the flats on the head of the bolt. Tighten the axle nut to the proper torque which can be found in the "Chassis Torque Specifications" chart. Using a new cotter pin to secure the axle nut is recommended.

Be sure that the lockplate tabs (2) are bent against the flat of the anchor bolt (3)

DISC BRAKE



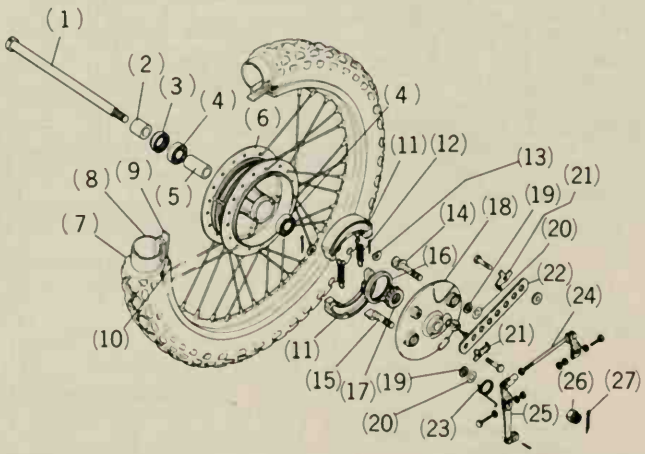
1. Disconnect the speedometer cable from the drive housing at the front wheel after removing the phillips head set screw.
2. Remove the cotter pin from the axle nut and loosen the axle nut a few turns.
3. Support the front wheel off the ground by placing a stand under the engine.
4. Remove the axle nut and pull the axle out using a phillips head screwdriver or similar tool.

CAUTION: *Do not operate the brake lever when the front wheel is removed. To do so will advance the ratchet adjuster to a point where the disc will not fit between the pads when the wheel is installed. If this should happen, the caliper will have to be disassembled and the adjusting screw in the brake arm loosened. Refer to the "Front Disc Brake" section.*

5. Remove the speedometer drive housing from the right-side of the hub and the side collar from the left-side.
6. To install the wheel, apply some grease to the inside of the oil seal in the right-side of the hub, and install the side collar into the oil seal. Apply a small amount of grease to the inside works of the speedometer drive housing, install the housing on the right-side of the hub.
7. Place a light coat of grease on the axle, hold the wheel in place with the disc located between the disc pads and slip the axle into place from the right-side. Position the speedometer drive housing so that the cable is not excessively bent when connected to it. Install the axle nut and tighten to the specified torque which can be found in the "Chassis Torque Specifications" chart. With the nut torqued in the proper range, line up a hole in the axle with a slot in the nut and install a new cotter pin.

Rear Wheel Removal and Installation

1. Remove the exhaust system (CB models only).
2. Remove the adjusting nut from the end of the brake rod. Apply the rear brake and remove the rod from the brake arm. Place the clevis pin, spring, and adjusting nut on the brake rod for safekeeping.
3. Remove the masterlink from the rear chain. Remove the chain from the sprocket and install the masterlink on one end. Do not remove the chain from the countershaft sprocket.
4. Remove the cotter pin, nut, plain washer, and rubber washer from the brake anchor bolt and separate the brake anchor from the brake plate.



Rear brake anchor

5. Remove the cotter pin from the axle nut, and remove the nut. Pull the axle out from the right side, and remove the wheel.

NOTE: *Place the wheel spacers, and the chain adjusters on the axle in the order in which they were removed and screw on the axle nut.*

6. To install the wheel, hold the wheel, axle spacers, and chain adjusters in place and slip the axle through. Install the axle nut hand-tight. Wrap both ends of the chain around the sprocket and install the masterlink. Adjust the chain tension.

8. Slip the clevis pin into the brake arm and insert the brake rod through it. Screw on the adjuster nut until the brake lever has about 1 in. (25 mm) free-play. Tighten the axle nut.

Wheel Bearings

Removal of the wheel bearings necessitates removing the hub oil seals. These must be replaced with new ones upon reassembly.

REMOVAL

1. Remove the wheel and take out the brake plate (drum brakes). On disc brake wheels, remove the speedometer drive mechanism.

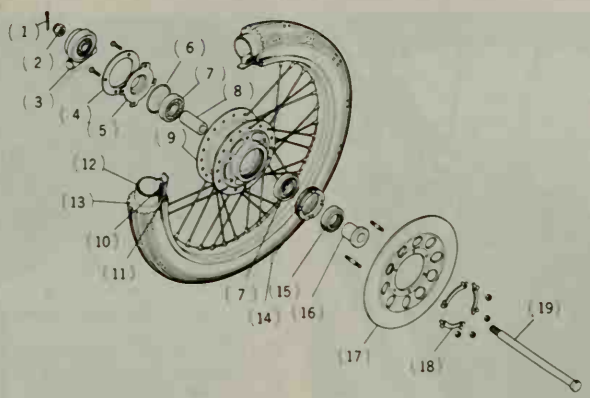
2. Drum brake wheels: On rear wheels, remove the circlip securing the sprocket to the hub and tap the sprocket off. Remove the oil seal from the side of the hub opposite the brake plate, and the snap-ring from beneath the oil seal. On front wheels, remove the oil seal from the right-side of the hub.

3. Disc brake wheels: Remove the four screws from the right-side of the hub and remove the speedometer drive retainer, retainer cover, and the O-ring. Unscrew the bearing retainer from the left-side of the hub being careful not to damage it. The oil seal can be removed from the retainer for replacement if damaged.

4. To remove the wheel bearings use a blunt punch and hammer. Remove the bearing in the left-side of the hub first. Reach through the center of the hub and tap the inside of the bearing evenly around its circumference to remove it. Be sure that the bearing does not become cocked to one side on removal. After the first bearing has been removed, remove the spacer tube from the center of the hub. Remove the second bearing using a driver large enough to cover the inside race of the bearing. A round piece of hardwood can be used. If the bearings resist removal, gently heat the bearing bosses in the hub with a propane torch and then try to tap them out.

INSTALLATION

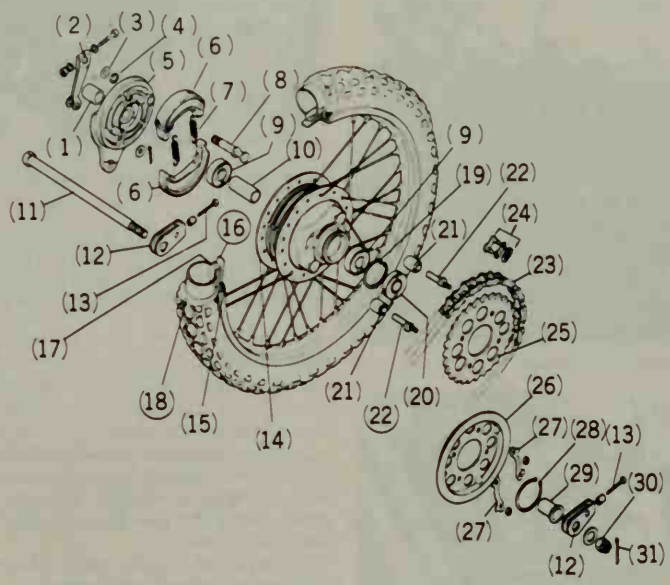
Assembly is in the reverse order of disassembly; however, note the following points:



1. Obtain a good grade of wheel bearing grease (such as Lithium or Moly) to lubricate the wheel bearings.

2. Pack the wheel bearings until they are completely filled.

3. Apply some grease to the inside of the hub and drive one of the wheel bearings into its seat. Install the retainer or snap-ring if so equipped. Install the spacer tube and drive the other bearing into its seat. The sealed surface of the wheel bearings must face the outside of the hub.



NOTE: *When a bearing retainer is fitted, the bearing closest to the retainer should be installed first. Then install and tighten the retainer, spacer and the other bearing.*

4. Install any oil seals. Be sure that they are driven straight into their seats. Coat the lips of the seals with grease before installing the axle.

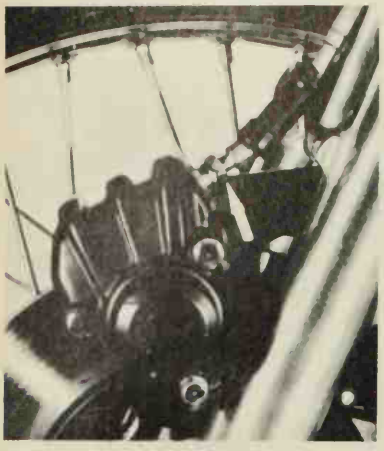
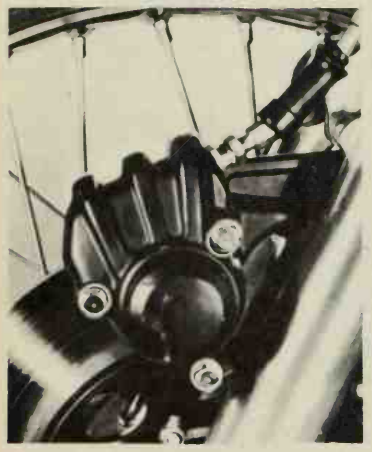
Front Disc Brake



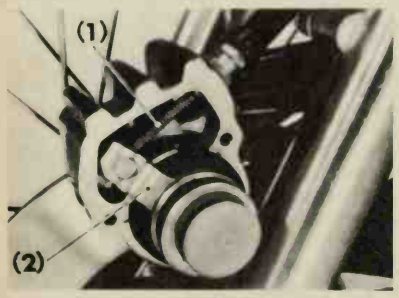
DISASSEMBLY

1. Slide the rubber boot on the lower part of the brake cable up on the cable to expose the brake cable adjuster in the caliper body. Loosen the locknut on the adjuster, and screw the adjuster into the caliper body as far as it will go.



2. Remove the three 6 mm bolts from the caliper cover, and remove the cover and the ratchet fixing spring. Pull the ratchet adjuster from the brake arm. Remove the brake arm, and disconnect the brake cable.

CAUTION: *Cover the brake arm in a clean cloth or a plastic bag to prevent dirt from entering the inside of the mechanism. The brake arm should not be disassembled; if defective, it should be replaced.*



3. The thrust guide plate can now be removed from the caliper body. To remove the disc pads, screw one of the cali-

Remove the thrust guide plate (3), and use a 6 mm bolt (2) to withdraw pad (1)

per cover bolts (6 mm) into the threaded hole in the back of pad A (the pad to the outside of the disc). Using the bolt, pull the pad out of the caliper. Remove the front wheel. Pad B (pad to the inside of

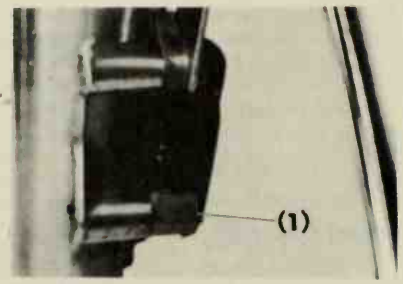
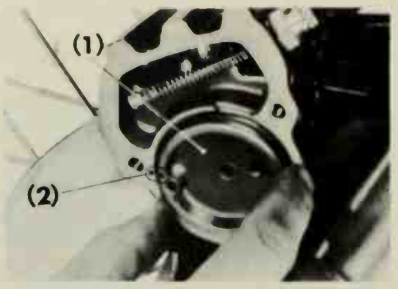
the disc) can be removed by pushing on the lockpin on the back of the caliper body. Remove the pad from the left-side of the caliper.

Disc cover (1), caliper body (2), caliper joint (3), caliper pivot pin (4)



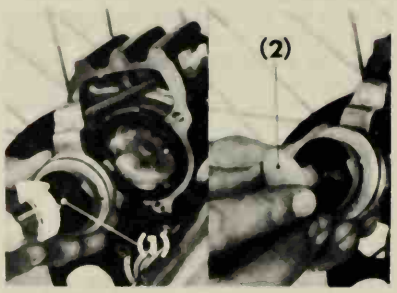
4. Remove the two 6 mm and one 8 mm caliper mounting bolts from the left fork leg. Remove the disc cover, caliper body, caliper joint, and caliper pivot pin.

INSPECTION



1. Inspect the brake pads for wear. If either pad is worn past the red wear limit line, replace both pads.
2. If the pads are scored they should be replaced. Minor score marks can be removed with sandpaper; however, take care to sand the pad flat and parallel to the disc surface.
3. Inspect the condition of all O-rings. Replace any which are damaged.

ASSEMBLY



1. Install an O-ring on the caliper pivot pin and apply some chassis grease to the pin. Slip the pin through the caliper and install the remaining O-ring on the top of the pin. Slip the caliper joint over the end of the pin. Install the caliper assembly to the left fork leg, locating the disc cover to the lower (8 mm) mounting bolt. Be sure that the pivot pin is installed correctly and that the lockplate is in place on the lower mounting bolt.
2. Place a small amount of silicon grease (KS62M) on the back of pad B, and install pad B into the right-side of the caliper, locating the lockpin through the hole in the back of the caliper.
3. Install the front wheel.
4. Place a new O-ring on pad A and coat the entire circumference of the pad with a thin layer of silicon grease (KS62M). Install the pad into the caliper aligning the punch marks on the pad and the caliper body as the pad is installed.

Be sure that the caliper pivot pin (1) is installed correctly

When installing pad "A" (1), line up the punch marks (2)

Turn the adjusting screw (1) counterclockwise until resistance is felt. Install the ratchet adjuster (2)

5. Install the thrust plate guide into the caliper. Connect the brake cable to the brake arm. With a small screwdriver, turn the adjusting screw in the center of the brake arm counterclockwise until resistance is felt. The adjusting screw should turn freely. Install the brake arm.
6. Install the ratchet adjuster, locating it into the slot in the adjusting screw. Install a new caliper cover gasket, the caliper cover, and ratchet fixing spring. Secure the cover with the three cover bolts.
7. Screw the adjusting bolt out of the caliper body all the way. Then screw in the adjuster until there is slack in the cable. From this position turn the adjuster out another 2 to 3 turns.
8. Operate the hand lever about 10 times. The lever should automatically adjust itself to the proper free-play of 20–30 mm (0.8–1.2 in.), measured at the tip of the lever.
9. After adjustment is correct, slip the rubber boot over the cable adjuster. Raise the front wheel off the ground and check that the wheel spins freely.

PAD REPLACEMENT

1. The procedures for removing and installing the pads for replacement are given under "Front Disc Brake—Disassembly" and "Assembly." However,

Step 4 "Disassembly," and Step 1 under "Assembly" can be omitted.

CABLE REPLACEMENT

1. Remove the cover from the left-side of the caliper. Screw the cable adjuster into the caliper body as far as possible. Remove the brake arm with the ratchet adjuster in place and disconnect the cable from the brake arm. Screw the adjuster out of the caliper body and remove the cable from the caliper.
2. Remove the rubber boot from the hand lever, disconnect the cable from the lever, and remove the cable.
3. Connect the new cable to the hand lever and replace the rubber boot.
4. Screw the cable adjuster on the new cable all of the way into the caliper body. Connect the cable end to the brake arm and install the brake arm into the caliper body. Install the caliper cover. Turn the cable adjuster out of the caliper until there is no slack in the cable and then turn the adjuster out another 2 to 3 turns.
5. Operate the hand lever about 10 times. The lever should automatically adjust itself to the proper free-play of 20–30 mm (0.8–1.2 in.), measured at the tip of the lever.

BRAKE DISC

The brake disc normally requires no service of any kind. However, if the disc becomes scored for any reason, it should be replaced and a new set of pads should be installed. A badly scored disc will reduce the effectiveness of the brake and shorten pad life considerably. If the front brake lever oscillates or fluctuates when the brake is applied at speed, the indication is that the brake disc is warped or bent. Check the runout of the disc with a dial indicator and replace it if run-out exceeds 0.012 in. (0.3mm). To replace the disc:

1. Remove the front wheel.
2. Bend back the locktabs, unscrew the six nuts, and remove the disc from the hub.
3. Mount the new disc on the hub and tighten the nuts evenly, using new locktabs to secure the nuts.
4. Examine the brake pads and replace them if they are close to the limit of wear or have worn in an unusual pattern.

Drum Brake Service

All models use a single-leading shoe rear brake, while, with the exception of the CB200, a single or twin-leading shoe is used on the front brake. Hondas use brakes in which the lining is bonded to the shoe. Lining and shoe, therefore, are purchased and replaced as a single unit.

1. Brakes can be inspected in place on the brake plate.
2. Inspect the lining for wear. There should be at least 0.06 in. (1.5 mm) of lining left at the thinnest point, or the linings must be replaced.
3. Inspect the linings for scoring or grooves. These may be caused by particles of dirt which have entered the drum. If badly scored, the shoes should be replaced. If scoring of the shoes is evident, it would be wise to inspect the brake drum for the same type of damage.

Removing brake shoes from the plate

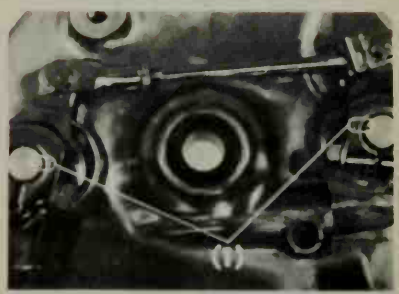
Be sure that there is no oil or grease present on the linings. Oil-impregnated linings must be replaced. If the linings do show this condition, determine the source of the lubricant: defective wheel bearing oil seals, excessive chain lube, etc.

4 If the linings are usable, rough up the surface with sandpaper. Then clean the linings thoroughly with alcohol or lacquer thinner. Clean the brake drum with the same solvent.

5. To disassemble the brake plate, simply grasp each shoe and fold them toward the center of the brake plate as shown. They may be installed using the same method.
6. Remove the brake springs. Remove the brake lever pinch-bolt(s) and pull the lever(s) off the splined brake camshaft(s).

NOTE: *The plurals refer to twin-leading shoe brakes.*

7. Push the brake cam(s) out of the plate from the outside using hand pressure or by tapping with a plastic mallet. Note the presence of any shims on the cam(s) and be sure they are in place when the brake plate is reassembled. Remove the dust seal(s) from the brake plate.
8. Check that the brake lever pinch-bolts are not bent. This can easily happen if they are overtightened. Replace any bolts in this condition. Inspect the brake lever splines and replace the lever(s) if these are worn or torn.
9. Inspect the splines on the brake cam(s). These should be in good condition. Check that they can rotate freely in the brake plate passage. If it will not, use a fine grade of sandpaper on the camshaft and the surface of the brake plate passage.
10. Clean the cam(s) thoroughly in a solvent to remove any old grease, rust or corrosion. Use sandpaper or emery cloth to polish the cams. Clean off any residue; before reassembly, smear the cams with chassis grease.
11. Inspect the brake plate for cracks or fractures, and replace it if necessary.
12. On twin-leading shoe brakes, the brake plate linkage should be checked for wear, especially on high mileage machines, and replaced if necessary.
13. Check the condition of the brake springs, noting any twisted or fatigued hooks. Replace any broken, rusted, or old springs with new ones.
14. Clean all parts thoroughly with a suitable solvent, making a special effort to remove the dust and built-up dirt from the backing plate.
15. When reassembling the hub, note the following points:



a. Ensure that the brake cams are lubricated with chassis grease and that any shims which were on the cams are in place;

b. The use of new dust seals is recommended;

c. Lubricate the brake shoe pivot points with a little grease;

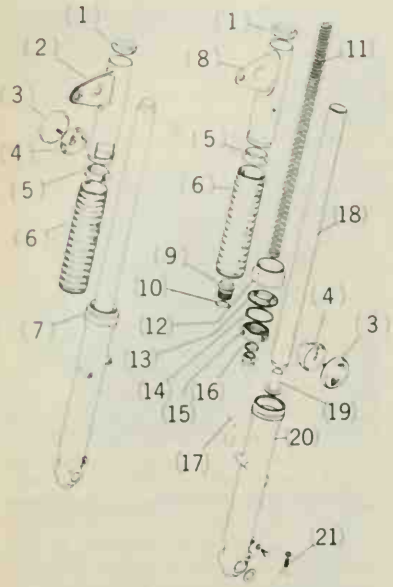
d. Install the shoes as on removal. Hook them together with the springs, and fold them down over the brake cam(s) and pivot(s);

e. Install the brake lever(s) so that the punch mark on the lever is in line with the punch mark on the brake cam, if fitted.

When installing the brake rod, line up the punch marks (1)

FRONT FORKS

Removal



1. Loosen the fork filler caps at the top of each fork leg. If the upper triple clamp is not fitted with fork leg pinch-bolts, the filler caps will have to be removed.
2. Support the front wheel off the ground by placing a stand under the engine. Remove the front wheel.
3. On disc brake models, remove the caliper from the left fork leg.
4. Remove the front fender.
5. Loosen the lower triple clamp pinch-bolts. Loosen the upper triple clamp pinch-bolts (if fitted). Spread the lower triple clamp with a small wedge and pull the fork legs out from the bottom one at a time.

Disassembly

CB/CL200, 175K7

The procedure is given for one fork leg, but it applies to both.

1. Remove the filler cap from the top of the fork tube and pour the oil into a suitable container to be disposed of.
2. Remove the spring(s) from the top of the tube.

3. Turn the fork upside-down and rest it on a block of hard wood. With an impact driver and the proper bit remove the allen bolt from the bottom of the slider. These bolts are installed with thread locking compound and trying to remove them without an impact driver will result in rounding the head of the bolt.

When the bolt is removed from the bottom of the slider, the damper rod complete with piston ring, and the rebound spring can be removed from the top of the fork tube.

5. The tube can now be pulled out of the slider. The piston will remain in the slider. Once the tube is pulled out the oil seal in the slider will have to be replaced.

6. Remove the dust cover and snap-ring from the top of the slider and pry out the oil seal with a hooked tool. The pin wrench from the Honda tool kit may be used by slipping the hooked end under the seal and tapping the handle with a hammer. A strip of copper or other soft metal can be used between the top of the slider and the handle of the wrench to protect the slider.

ALL OTHER MODELS

The procedure is given for one fork leg, but it applies to both.

1. Remove the filler cap from the top of the fork leg and pour the oil into a suitable container to be disposed of. Remove the fork spring.

2. Remove the dust seal, snap-ring, and washer from the top of the slider. Grasp the slider in one hand and the fork tube in the other and pull them apart with a sharp jerk.

3. Remove the circlip from the bottom of the fork tube, then the piston, two circlips, the sliding bushing and oil seal.

Inspection

ALL MODELS

1. Wash all metal parts in a solvent and dry.

2. Inspect the fork slider for cracked, broken, or distorted axle brackets, worn inner bore surfaces, damaged threads, or dents which have affected the inner bore. Replace the slider if defective in any of the above ways.

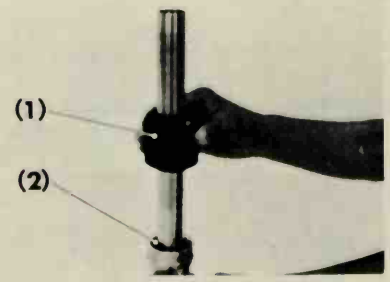
3. Inspect the fork tubes for condition: the chrome plating must be intact throughout. Check for damaged threads, and worn or scuffed inner or outer surfaces. Check the tubes for straightness. This is done by placing the tubes in a set of V-blocks and checking the run-out with a dial gauge. If the tube is bent more than 0.060 in. as indicated by the gauge, it must be replaced.

4. 200, late 175: Inspect the piston ring for scoring or wear.

5. Check the filler cap O-ring for cracks or any other signs of wear. Replace it if damaged.

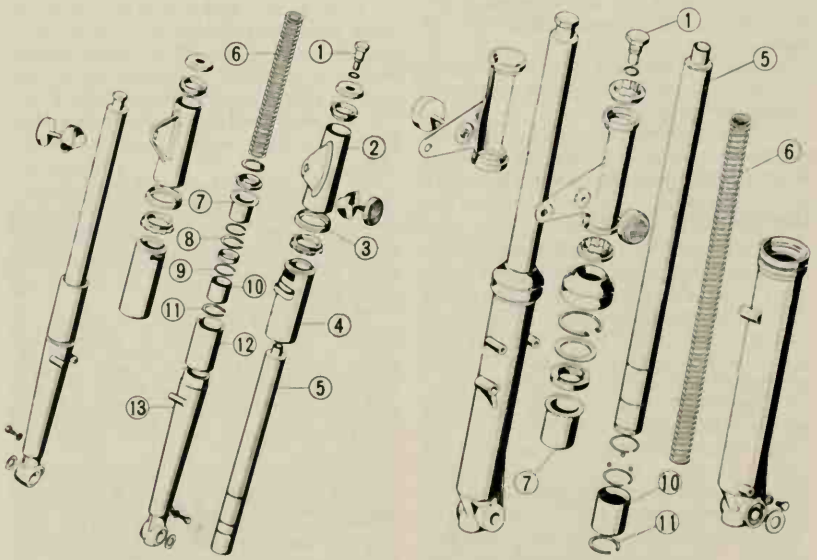
6. Check the general condition of the fork springs. Replace any which are badly rusted, have collapsed coils, etc. Compare the lengths of corresponding springs. They should be of approximately equal length. If the springs differ in length by more than ¼ in., both springs should be replaced.

7. Inspect the inside surfaces of the piston and sliding bushing for signs of wear or score marks. Replace as necessary. Place the sliding bushing on the fork tube and check for excessive play. The bushing should be a close fit.



8. Coat all parts with ATF before assembly. New oil seals must always be used.

Assembly



200, LATE 175

1. Be sure that the piston is in the slider. Lubricate the new oil seal with ATF and install it into the top of the slider. Place a block of hard wood over the seal and drive it straight into the slider as far as possible. Then place the old seal on top of the new one and drive them in until the new one clears the snap-ring groove in the slider. Take out the old seal. Be sure that the new seal is straight in the slider. The distance from the top of the oil seal to the snap-ring groove should be the same all around the seal. Install the snap-ring. Lubricate the lips of the seal.

2. Install the rebound spring and damper rod in the fork tube. Carefully install the slider on the tube. Replace the fork springs and cap temporarily. Turn the fork upside down and install the bolt in the bottom of the slider. The threads of this bolt should be coated with thread locking compound.

3. Fit the drain plugs; be sure to install the gaskets.

4. Remove the cap and fill the forks with the proper amount of ATF. Note that the amount added to rebuilt forks will be slightly more than for a normal fork oil change.

ALL OTHER MODELS

1. Install a new oil seal on the fork tube. Be sure to lubricate the seal with ATF before placing it on the tube.

2. Install the sliding bushing on the tube with the flange on the bushing facing the top of the tube. Install the two circlips, piston, and bottom circlip. All of the circlips must be a snug fit on the fork tube; if not replace them. Slide the fork spring into the tube from the bottom.

3. Place the fork tube into the slider and drive the oil seal into its seat in the top of the slider. Replace the washer, snap-ring, and dust seal.

4. Fill the fork leg with the proper amount of oil. Replace the top washer, O-ring, and filler cap.

Installation

ALL MODELS

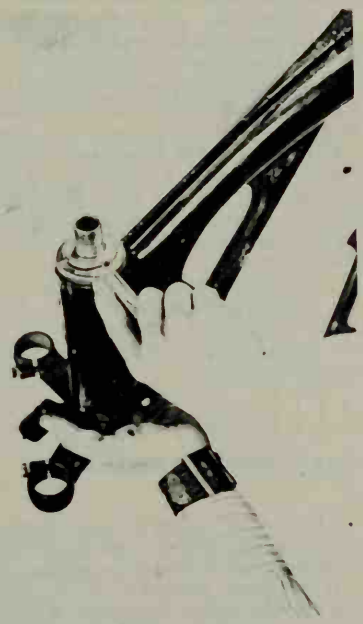
1. Refit the fork tubes through the triple clamps. The top of the fork tube should be even with the top of the upper triple clamp.

2. Tighten the pinch-bolts on the lower triple clamp, and then tighten the fork filler caps and the pinch-bolts on the upper triple clamp, in that order.

3. Fit the front wheel and check the operation of the forks.

STEERING STEM ASSEMBLY

Bearing Adjustment



On models equipped with a friction steering damper, the damper should be loosened (counterclockwise) as much as possible so that it does not interfere with the bearing movement while checking or adjusting the bearing. If an oil damper is fitted, remove it from the steering stem.

1. The steering stem bearings are uncaged #8 balls. They are adjusted by means of a ring nut beneath the upper triple clamp.

2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender, place your other hand beneath the lower triple clamp at the frame lug.

3. Attempt to move the forks by pulling up on the tip of the fender. If play or movement can be felt at the lower triple clamp, the bearings are adjusted too loosely or are worn.

4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.

Adjusting steering head bearings

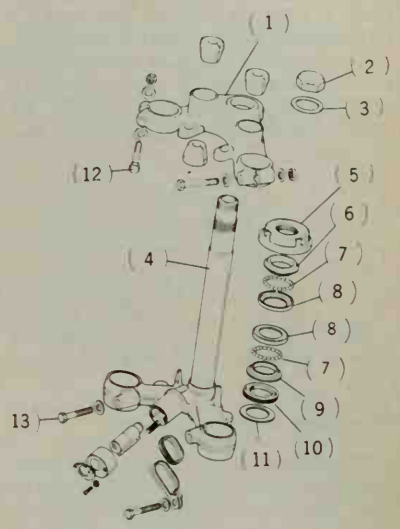
5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The forks should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

6. To adjust the bearings, remove the front wheel, front forks, handlebars, and the upper triple clamp. The bearings are adjusted by means of the adjuster nut under the upper triple clamp.

7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above. Temporarily install the forks, upper triple clamp, and the steering stem nut to check the adjustment.

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Disassembly



1. Remove the front wheel, front forks, and handlebars. If a friction steering damper is fitted, remove it by removing the two cotter pins from under the lower triple clamp, and unscrewing the damper rod and removing the friction plates. If an oil shock damper is fitted, unbolt it from the lower triple clamp.

2. Unscrew the steering stem nut and disconnect the speedometer and tachometer cables from their instruments. Remove the upper triple clamp.

3. Disconnect the wiring inside the headlight shell, and remove the headlight shell and the fork ears.

4. Loosen the steering stem adjuster nut with a pin wrench, then hold the steering stem up while unscrewing the adjuster nut the rest of the way off. Remove the steering stem top cone race and the ball bearings from the top race.

5. Carefully pull the steering stem out from the bottom. Some of the ball bearings from the lower race will probably fall out at this time so be prepared for this.

12. Upper triple clamp pinch-bolt
13. Lower triple clamp pinch-bolt

Removing the steering stem

6. Remove the bottom cone race, dust seal, and dust seal washer from the steering stem if they are to be replaced. These will have to be pried off with a chisel, therefore only remove them if necessary.

7. The bearing races in the frame lug are a press-fit and should not be removed unless replacement is necessary. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable punch and tapping the race evenly around its circumference to remove it from the inside of the

frame lug. Be sure that the race does not become cocked in its seat upon removal.

New races are installed with a suitable sized bearing driver, i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.

Removing the frame races with a drift

These races can also be installed using a block of hardwood of sufficient size to cover the race in place of a bearing driver.

Inspection

1. Wash the ball bearings in a suitable solvent.
2. Clean all of the old grease from the bearing race surfaces, steering stem, and frame lug.
3. Inspect the bearing race surfaces. They must be clean and smooth. That is free from any cracks, scoring, rust, or indentations. Run your finger around each of the bearing races. Note any roughness or ripples on the race surface. If any imperfections are noted, both the sets of races and all of the balls must be replaced.
4. Check the balls themselves for rust, pitting, scoring, or flat spots. If the balls are found to be defective in any way, the balls and both sets of races must be replaced.

NOTE: *Balls and races must always be replaced in a set as worn races will destroy new balls and worn balls will destroy new races.*

5. Check the dust seal for condition and replace if torn or cracked.
6. Check the steering stem for cracks or a bent condition; this is especially important if the bike has been involved in a spill.

Installation

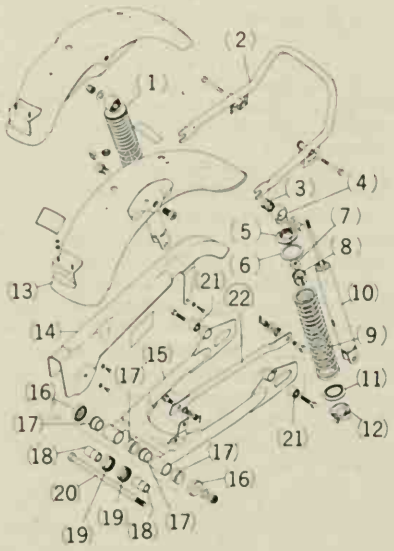
1. Install the dust seal washer, dust seal, and lower cone race on the steering stem. Use a good grade of bearing grease to coat the bottom cone race and the upper race in the frame lug.
2. Embed 18 balls into the grease of each race.
3. When the balls are in place, slip the steering stem through the frame lug and hold it in place while refitting the top cone race and threading on the adjuster nut.
4. Tighten the adjuster nut all of the way by hand, rotating the steering stem to work the grease into the balls.
5. Tighten the adjuster nut until the steering stem turns freely, but has no play.
6. Install the fork tubes, headlight assembly, and upper triple clamp, flat washer, and steering stem nut. Check that the stem moves freely of its own weight from 5°–10° off center; if not, check for:
   a. Steering bearing too tight;
   b. Bent steering stem;
   c. Worn races or balls.
7. Install the front fender, front wheel, and handlebars.

REAR SHOCK ABSORBERS

The damper unit of the rear shock absorbers cannot be serviced; therefore, if defective, the unit must be replaced.

If the shock absorbers are somewhat old, and one fails in the course of normal usage, it would be a good idea to replace both shocks to ensure equal damping characteristics.

CAUTION: *Do not attempt to disassemble the damper unit of the rear shocks. These contain gas under high pressure.*



To check a shock which is removed from the machine, place the bottom end on the ground and use the weight of your body to compress it as much as possible. Release the shock and note the rebound behavior. If the shock returns quickly at first, then slowly returns to the normal length, it is serviceable. If it returns to its normal length all at once, it should be replaced.

SWING ARM

All Models

INSPECTION

1. Disconnect the chain. Remove the rear wheel and sprocket assembly.
2. Remove the shock absorbers and chain guard.
3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced or fixed.
4. Check that the rear wheel mounting plates are parallel.
5. Grasp the legs of the swing arm and attempt to move it from side-to-side. Any
6. Lubricate the new bushings and both the inside and outside of the inner collar with a good chassis grease. Press in

noticeable side-play will indicate that the swing arm bushings and center collars need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

REMOVAL AND INSTALLATION

1. Proceed as above. Then unscrew the swing arm pivot bolt nut, and pull out the pivot bolt.
2. Remove the swing arm.
3. The swing arm should be inspected for cracks or fractures, especially around the welds.
4. After removing the swing arm, the dust seals and the swing arm bushings can be replaced. This should be done every 10,000 miles or more often depending on how the machine is used, or if the bushings are worn.
5. Using a small drift, push the center collar out of the swing arm. Remove the bushings, tapping them out with a long drift and hammer. Once the bushings are removed, they should be replaced.

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*

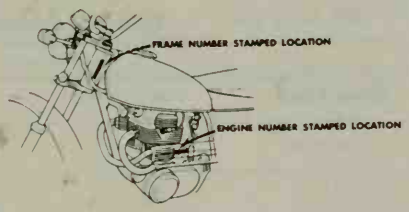
LUBRICATION

Checking Oil Level

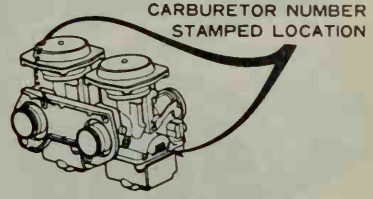
When the motorcycle is on the center stand on level ground, the oil level should be between the maximum and minimum marks on the dipstick with the filler cap resting on the top of the threads of its hole.

Maintain oil level between upper and lower dipstick marks. Note that the dipstick must rest on the top of the threads when checking

Changing Oil



The oil should be changed every 1,000 miles after the break-in period. The oil should be changed when warm.



1. Remove the oil filler cap, and the drain plug. After allowing a minute for the oil to drain, kick the engine over a few times with the kick-starter (be sure that the key is off) to remove any oil in the delivery system.
2. Refit the drain plug and add 1½ qts of the correct grade of oil. Run the engine for a minute or two, then shut it off; wait one minutes and check the oil level. Add oil as necessary to bring the level up to the maximum mark on the dipstick.

Oil Filter

A centrifugal oil filter is used on all models. As the oil passes through the spinning filter, dirt particles are forced to the outside of the filter housing and the clean oil passes through the center of the filter into the right crankcase cover. The filter should be cleaned every 6,000 miles or 12 months.

1. Clean the oil filter in conjunction with an oil change. Drain the oil, but do not reinstall the drain plug.
2. 350 models only: Remove the three screws from the circular cover plate on the right crankcase cover. Remove the cover. Pry slots are provided for a small screwdriver.
3. 360 models only: Remove the right step bar, kick-starter lever, and right crankcase cover.
4. Remove the circlip from the oil filter. Screw a 6 mm (crankcase cover) screw into the center of the filter cap; this will pull the cap off.

filter housing, and secure with the circlip.

8. On 350 models, install the cover plate using a new O-ring or gasket if necessary.

NOTE: *When installing the filter cover plate on 350 models be sure that the oil holes in the cover plate and the right crankcase cover line up.*

9. On 360 models, install the right crankcase cover, kick-starter lever, and right step bar.

Front Forks

1. ATF is recommended for the front forks. If slightly stiffer damping characteristics are desired, use SAE 20 or SAE 30 oil.

2. Fork oil should be changed every 3,000 miles or once every 6 months.

3. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Allow the oil to drain for several minutes into a suitable container, then pump the forks up and down several times. After most of the oil is expelled, turn the forks all the way to the right to completely drain the right fork leg, or all the way to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit the drain plug and tighten it securely.

4. Repeat the procedure with the other fork leg.

5. Support the front wheel off the ground. Remove the fork filler caps from the top of each fork leg; it may be necessary to remove the handlebar holders and place the handlebars out of the way. Loosening the upper triple clamp pinchbolts (if fitted) may make removal easier. On models with internal fork springs, the front end of the motorcycle can be lowered to force the springs out of the fork tubes. Either move the spring to one side or remove it altogether to aid filling the forks.

6. Add the correct amount of ATF to each fork leg. Capacities for each model are given in the "Maintenance Data" chart at the end of this section.

Chassis Lubrication

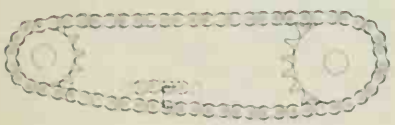
1. The swing arm pivot is fitted with two grease nipples on most models. These should be lubricated with a good grade of chassis grease every 3,000 miles. Grease should be applied until some of it shows at either end of the swing arm.

2. Wheel and steering head bearings are lubricated with bearing grease. This should be done every 6,000 miles.

Late models have the swing arm grease fitting in the middle of the swing arm. Lubricate it in the same manner as the earlier type.

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain



1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.

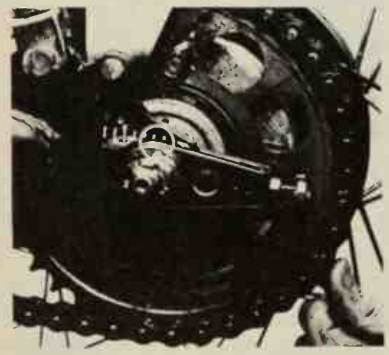
Check chain free-play in the middle of the lower chain run

2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on the center stand so that the rear wheel is off the ground;

b. The transmission should be placed in Neutral;



c. The chain should be clean and well-lubricated;

d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably sprockets which should be replaced as soon as possible.

3. To adjust the chain, first back off the rear brake adjuster nut if a rod-operated brake is fitted.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each chain adjuster bolt.

5. Turn each of the adjuster bolts in or out by equal amounts until the chain tension is approximately correct.

Adjusting chain free-play. Be sure that the adjuster (circle) indicates the same aligning mark on each side of the swing arm.

6. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

7. Tighten the axle nut and check the chain tension. The chain tension should also be checked with the weight of a rider sitting on the motorcycle when it is off the center stand; the chain should still have at least ½ in. of free-play. Correct if necessary. After adjustment is correct, torque the axle nut to the proper torque, 72 ft lbs. Fit a new cotter pin and tighten the adjuster locknuts.

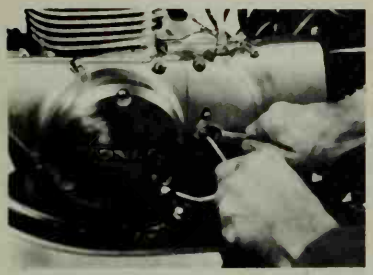
Clutch

Two adjustments are made to the clutch: cable adjustment and pushrod adjustment. Usually the pushrod need not be adjusted unless the clutch malfunctions. Cable adjustment must always be maintained at the proper specification.



Before adjusting the clutch, apply a few shots of chassis grease to the adjuster grease fitting and operate the clutch lever a few times to distribute the grease. The clutch cable should also be well-lubricated.

1. The clutch lever should be able to be moved 10–20 mm (0.4–0.8 in.) measured at the tip of the lever before the clutch begins to disengage. If clutch operation is not satisfactory after this adjustment is made, proceed as follows:

Clutch cable free-play is measured at the tip of the clutch lever

2. Loosen the locknut on the handlebar adjuster and screw the adjuster into the lever housing to give as much slack in the cable as possible.

Adjusting the clutch

3. Loosen the locknut on the cable adjuster located at the top of the left rear crankcase cover, and screw the adjuster into the crankcase cover.

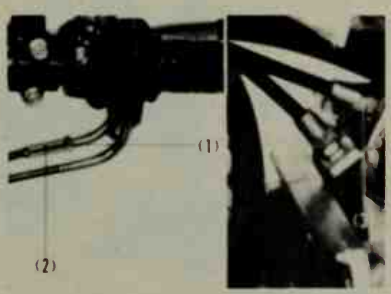
4. Loosen the locknut on the pushrod adjuster located on the left rear crankcase cover. Screw the adjusting screw counterclockwise until a noticeable resistance is felt, then turn the adjusting screw clockwise ¼ turn. Tighten the locknut.

5. Back the cable adjuster on the crankcase out until there is approximately 10–20 mm (0.4–0.8 in.) of free-play measured at the tip of the lever. Tighten the locknut.

6. Minor adjustments can be made at the handlebar adjuster.

7. Use the handlebar adjuster to maintain the correct amount of free-play.

Throttle Cable



The throttle cable free-play should be adjusted *after* the idle speed. The standard throttle cable free-play is 10–15° of grip rotation for all models. The cable should be well lubricated before attempting to adjust free-play.

360 MODELS

1. Loosen the locknut on the cable adjuster located near the twist-grip and screw the adjuster in to give the maximum amount of free-play.

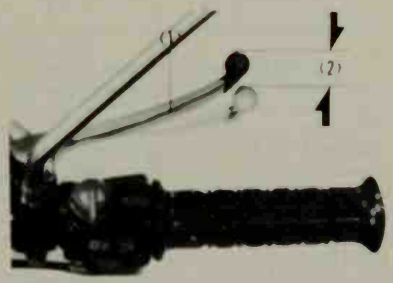
2. Loosen the locknut on the lower adjuster. Turn the adjuster until there is approximately 10–15° of play at the twist-grip, then tighten the locknut.

3. Fine adjustment is accomplished with the adjuster near the twist-grip. Be sure to tighten all locknuts when the adjustment is correct. Check cable operation and free-play when the handlebars

Throttle cable adjusters (2 and 3) and locknut (1) (360)

are cut hard right or left. If it changes, either the cable is too tightly adjusted or is binding somewhere.

350 MODELS

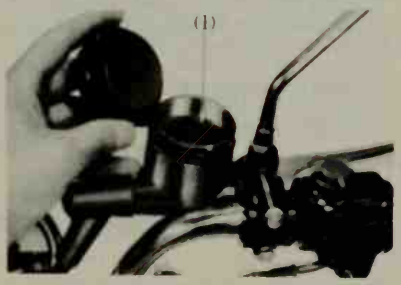


1. Cable free-play is adjusted with the adjuster near the twist-grip. Loosen the locknut on the adjuster and screw the adjuster in or out until free-play is correct. Tighten the locknut.

2. Check that the cable operates smoothly and maintains some free-play when the handlebars are cut all the way to the right or left. If the idle speed changes when this is done, the cable is either too tightly adjusted, or it is binding somewhere along its routing.

Front Drum Brake

1. Use the cable adjuster on the brake plate to allow about 20–30 mm (0.8–1.2 in.) of handlebar lever free-play before the shoes contact the drum. This free-play is measured at the tip of the lever.



2. This free-play can be maintained as the shoes wear by using the adjuster at the handlebar lever.

On front drum brakes, the brake lever should have about 1 in. of movement (measured at the end of the level) before the linings contact the drum

Disc Brake

Disc brakes need no attention other than a periodic check of the fluid level and pad wear.

Maintain brake fluid level at the level line

1. After removing the reservoir cap and rubber diaphragm, check to see if the fluid is up to the level mark on the inside of the master cylinder. If the level is below the level mark, add enough DOT 3 brake fluid to bring the level up to the mark. Reinstall the diaphragm and the cap, and tighten securely.

2. Check the brake pad wear, and replace the pads in a set if either one is worn past the red limit line.

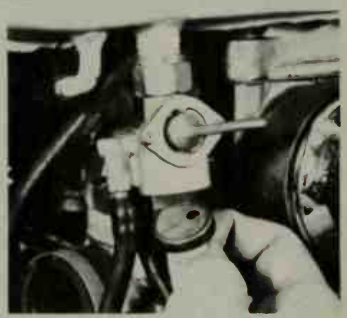
Rear Brake

Use the adjusting nut on the end of the cable or rod so that the brake pedal has 1 in. of free-play before the shoes contact the drum. The pedal height can be adjusted with the stopper bolt.

Check pedal free-play with a rider on the machine.

Brake Light Switch

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch is mounted in a slotted bracket and secured by locknuts. Moving the switch up on the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Do not turn the switch to adjust it as the wires will become twisted and may break. Generally, the brake light should come on just as the linings contact the drum. The front brake light switch is not adjustable and must be replaced if defective.



Steering Stem Bearings

The steering stem bearings should be checked periodically and adjusted if necessary. Refer to the "Chassis" section.

FUEL SYSTEM

1. Fuel system maintenance involves cleaning the petcock and filter, cleaning or replacing the air cleaner, and cleaning the carburetors.

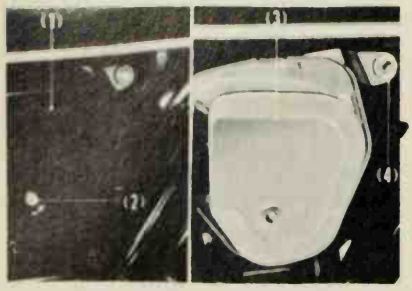
2. The carburetors should be removed, disassembled, and cleaned every 4,000 miles.

Removing the filter screen and O-ring

3. The petcock should be serviced every 3,000 miles. Shut the fuel off, then unscrew and remove the petcock sediment bowl. Take out the O-ring and fuel filter screen. Clean the parts in solvent and inspect the screen for any holes or other defects, replace it if it is damaged in any way. Inspect the O-ring for any cuts or cracks and replace it if necessary. Reinstall the filter screen, O-ring, and sediment bowl. Turn the fuel on and check for leaks.

AIR CLEANER SERVICE

The air cleaner should be serviced or replaced every 1,500 miles or more often depending on conditions.



All Except SL350K1-K2

REMOVAL

1. Open the seat. On CL models the

exhaust system must be removed. Remove the right and left sidecovers.

2. Loosen the air cleaner connecting band. Remove the bolt running through the center of the air cleaners, and the air cleaner element mounting bolt.

Air cleaner cover (1), cover mounting bolt (2), element (3), and element mounting bolt (4)

3. Remove the air cleaner cover and the air cleaner element.

CLEANING

1. Tap the air cleaner to remove any loose dirt. Blow compressed air through the element from the inside out.

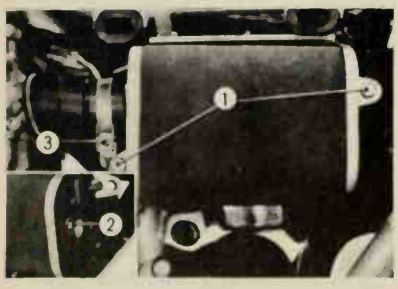
2. Inspect the element and connecting tube for any holes; replace any air cleaner found defective. An oil-impregnated element or one which cannot be cleaned sufficiently should also be replaced.

3. Inspect the area where the element is bonded to the mounting plate. If the bonding is cracked or separated replace the element.

INSTALLATION

1. Installation is in the reverse order of removal.

2. After installing the air cleaners, start the engine and check for any air leaks.



SL 350K1-K2

REMOVAL

1. Remove the plastic sidecovers from both sides.

2. Remove the two mounting bolts, and loosen the connecting tube band. Remove the air cleaner.

3. Remove the bolt from the center of the back of the air cleaner and remove the element.

Foam-type element (SL models): air cleaner mounts (1), element mount (2), carburetor clamp screw (3)

CLEANING

1. Once the air cleaner element is removed, it should be cleaned in a clean solvent such as kerosene.

2. When the air cleaner element has dried thoroughly, soak it in gear oil SAE 90 until it is fully saturated then wring off the excess oil.

3. Inspect the element for any damage, such as holes or a damaged case. Replace any air cleaner found defective.

INSTALLATION

1. Installation is in the reverse order of removal.

2. Start the engine and check for any air leaks. Any air leaks should be corrected as they can cause a lean mixture resulting in possible engine damage.

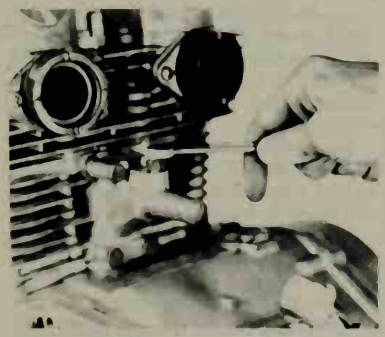
NOTE: *Common tune-up procedures are explained in detail in "General Information."*

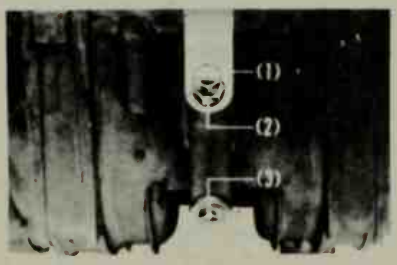
CAM CHAIN ADJUSTMENT



NOTE: *Early 350 models were equipped with an automatically-adjusting, hydraulic-type cam chain tensioner. No adjustment is possible. These early units can be replaced with the improved adjustable units found on later models with no internal engine modification.*

350 Models

1. Remove the left exhaust valve cover and the alternator cover. Remove the spark plugs.
2. Turn the engine over counterclockwise using the rotor bolt until the left exhaust valve just begins to open, then turn the engine in the opposite direction (clockwise) to 90° after the top dead center (ATDC) for the left cylinder. Refer to the accompanying illustration.
3. Loosen the locknut on the tensioner setting bolt and back the setting bolt out a few turns, the tensioner will automatically adjust itself. Tighten the setting bolt and locknut.



The engine is properly set up for cam chain adjustment when the left piston is 90° past TDC of its compression stroke, as indicated by the action of the valves and the position of the alternator rotor marks

Adjusting the cam chain (350)

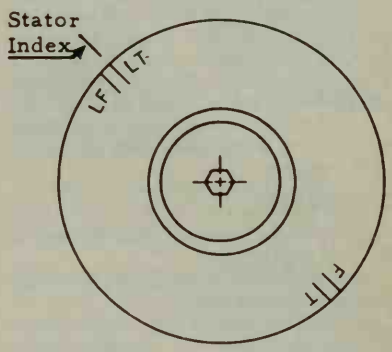
360 Models

1. Remove the stator cover and the left cylinder valve tappet covers. Remove the spark plugs. Using the rotor bolt, turn the crankshaft counterclockwise while watching the left cylinder intake tappet; when the tappet descends all the way and then starts to rise, line up the "LT" mark on the rotor with the index mark on the stator. In this position the left cylinder is at top dead center (TDC) of the compression stroke. Turn the crankshaft another 90° (counterclockwise). The valves should all be closed in this position. This is the only position that the cam chain tensioner may be adjusted in.

Cam chain setting bolt (1), locknut (2), and plunger cap (3) (360)

2. Loosen the setting bolt locknut and back the setting bolt out a few turns, the tension will automatically be adjusted. Tighten the setting bolt and the locknut.
3. If after performing the adjustment outlined above, the cam chain still is excessively noisy, perform the adjustment as described below.

NOTE: *When listening for cam chain noise the valves should be adjusted properly so that tappet noise will not be confused with cam chain noise.*



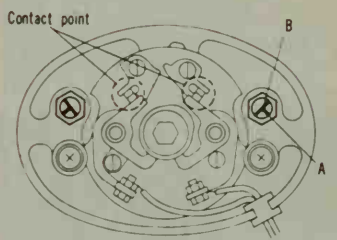
4. Start the engine and as soon as the engine will idle with the choke off, perform the adjustment by removing the plunger cap. Loosen the setting bolt locknut and back out the setting bolt a few turns. Push the tensioner plunger in with a screwdriver until the cam chain is silent and, while maintaining pressure with the screwdriver, tighten the setting bolt and locknut. Do not use more pressure on the plunger than is necessary, as this will overtighten the chain and cause rapid wear of the cam chain and the tensioner components. Install the plunger cap.

VALVE ADJUSTMENT

NOTE: *Valves must be adjusted when engine is cold.*

350 Models

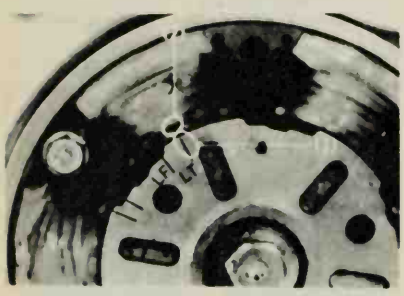
1. Remove the alternator cover, intake and exhaust valve caps, and the point and tach drive housing covers.
2. Remove the spark plugs.
3. Turn the engine over slowly in the normal direction of rotation (the rotor will turn counterclockwise) while observing the left intake valve. When the valve goes down and begins to come up, continue turning the engine over until the "LT" mark on the rotor lines up with the timing index mark on the stator.
4. The left piston should now be at top dead center (TDC) of the compression stroke with both valves closed. Check for clearance at both valves for the left cylinder. Each should have a slight amount of free-play. If they do not, the piston is at TDC on the exhaust stroke. Turn the rotor 360° and check again.



Alternator rotor marks indicating that the left cylinder is at top dead center

5. Valve clearance is 0.05 mm (0.002 in.) for the intake valves and 0.1 mm (0.004 in.) for the exhaust valves.
6. If adjustment is necessary, loosen the locknut on the rocker arm shaft (in the point and tach drive housings) and turn the rocker arm shaft until the adjustment is correct. Tighten the locknut and recheck the adjustment.

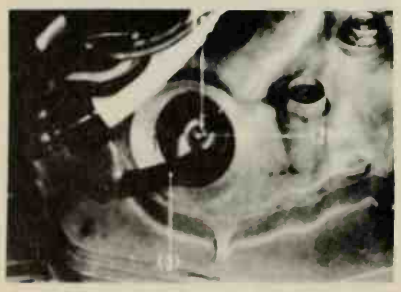
Adjusting the valves (350)



The index marks (A) on the rocker arm shafts (B) must be pointing away from the center of the cylinder head (350)

NOTE: *Each rocker arm shaft has an indicator slot. This slot must face the front of the engine on the exhaust valves and to the rear of the engine on the intake valves.*

7. After completing the adjustment of the left cylinder turn the rotor counterclockwise 180° and align the "T" mark on the rotor with the timing index mark on the stator. The right piston should be at TDC of the compression stroke and clearance should exist at both valves; if not turn the rotor 360°. Repeat the adjusting procedure for the right cylinder. Be sure to recheck the adjustment after tightening the rocker arm shaft locknut. Also check that the indicator slot in the rocker arm shaft is facing away from the center of the engine.



360 Models

1. Open the seat and raise the rear of the fuel tank slightly.
2. Remove the spark plugs, alternator cover, and valve covers.
3. Turn the engine over slowly in the normal direction of rotation (counterclockwise) while observing the left intake valve. When the valve goes down and then starts to rise, continue turning the engine over until the "LT" mark on the rotor lines up with the timing index mark on the stator.

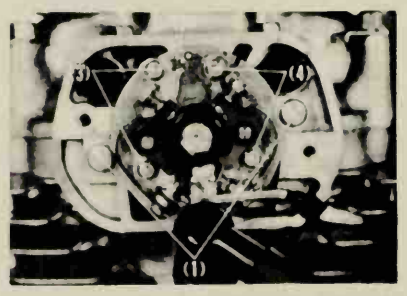
Left cylinder at top dead center when the rotor (1) and stator index mark (2) are aligned (360)

4. The left piston should now be at top dead center (TDC) on the compression stroke with both valves closed. Each valve should have a slight amount of freeplay. If they do not, the piston is at TDC on the exhaust stroke. Turn the rotor 360° and check again.
5. The correct valve clearance is 0.05 mm (0.002 in.) for the intake valves and 0.08 mm (0.003 in.) for the exhaust valves.
6. If adjustment is necessary, loosen the adjuster locknut and turn the adjuster to effect adjustment. Tighten the locknut.

Adjusting the valves: adjuster locknut (1), adjusting screw (2), and feeler gauge (3) (360)

NOTE: *The adjustment may change when the locknut is tightened. Hold the adjuster steady while securing the locknut. Recheck the clearance afterwards.*

7. Turn the rotor 180° counterclockwise and line up the "T" mark on the rotor with the timing index mark on the stator. In this position both valves for the right cylinder should be closed. Adjust the valve clearance as described for the left cylinder above.



CONTACT BREAKER POINTS

Location

1. The points are located in a case on the left-side of the cylinder head, and are operated off the camshaft. The timing advance mechanism is fitted behind the breaker point base plate.

Replacement

1. If replacement of the points is necessary, this is easily accomplished by disconnecting the primary wire from the points, removing the two point securing screws, and taking off the points. Install the new points after thoroughly cleaning off the contact surfaces with a non-oily solvent, and adjust the gap. If a breaker plate assembly is purchased simply disconnect the yellow and blue point wires from the wiring harness and remove the two breaker plate screws. Install the new breaker plate and connect the primary wires. Clean the surfaces of the points and adjust the gap. Whenever the points are replaced, the ignition timing will have to be set.

Breaker plate screws (1), point securing screws (3 and 4), pry point (2) (360)

2. Apply a bit of grease to the breaker cam lubricating wick. Take care not to apply too much to avoid fouling the points.

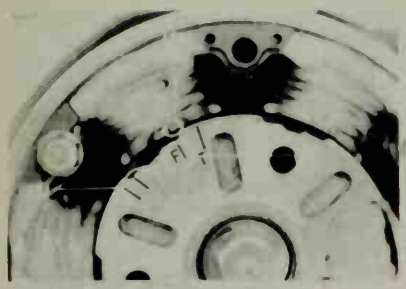
Gapping

Points should be filed (if necessary) and cleaned before gapping.

1. Remove the alternator cover, and points cover.
2. Using the rotor bolt, turn the engine over until one set of points is open to their maximum gap.
3. With the proper feeler gauge, check the gap. The proper specification for all models is 0.3–0.4 mm (0.012–0.016 in.). The feeler gauge should be a slip fit between the points if they are correctly gapped.
4. If adjustment is necessary, loosen the two screws which secure the points to the base plate, and use a thin screwdriver at the pry slot provided to bring the gap to the proper specification.

NOTE: *Loosen the screws just enough to allow the points to be moved. If too loose, the points will snap shut instead of holding the adjustment.*

5. Tighten the screws and recheck the gap. It may change slightly when the screws are tightened.
6. Repeat the procedure for the other set of points.
7. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the set of points should be replaced.



IGNITION TIMING

The method of adjusting the timing is the same regardless of the type of equipment used. The *left* cylinder is set *first* and timing is adjusted by moving the base plate. The points on the left-side of the base plate are those for the left cylinder. After the left cylinder is correctly timed, the right cylinder can be checked, and adjusted if necessary. To adjust the right cylinder timing, the point gap is varied so that the points open at the instant the timing marks align. A change in the point gap of 0.1 mm (0.004 in.) will change the timing 10°. Increasing the point gap will advance the timing, while decreasing it will retard the timing.

If correct timing cannot be accomplished with both point gaps set in the correct range of 0.3–0.4 mm (0.012–0.016 in.), the points should be replaced.

Dynamic Timing

1. Remove the alternator cover so that the timing marks are visible.
2. Hook up the timing light according to the manufacturer's instructions. Most lights use the vehicle's own battery as a power source.
3. Start the engine, aiming the light on the rotor. Note the following:
   a. At idle, the "LF" (left cylinder) mark or the "F" (right cylinder) mark on the rotor should line up with the timing indicator on the stator, depending on which plug the strobe light is connected to;
   b. As the revolutions increase, the "LF" or the "F" mark should be seen to move in a direction opposite that of the crankshaft rotation;
   c. Finally, at full advance (about 3,200 rpm and above), the twin rotor marks must line up with the timing indicator mark on the stator.
4. The full advance reading is the most important. If the rotor marks and the stator indicator do not align, proceed as follows:
5. Time the *left* cylinder *first*. Remove the points cover. Loosen the two screws which secure the breaker base plate just

Rotor timing marks: (1) firing point, (2) stator index, (3) full advance firing point

enough to allow the plate to be turned. Using a thin screwdriver applied at the pry point provided, rotate the plate in the direction necessary so that the timing marks align.

Rotating the plate clockwise advances the timing; rotating the plate counterclockwise retards the timing.

Tighten the base plate screws and recheck the timing.

6. Connect the timing light to the right cylinder and check the timing as for the left cylinder this time using the "F" mark on the rotor.

If the right cylinder timing is incorrect, loosen the two screws which secure the right-side points to the base plate. Open or close the point gap so that the timing marks align as the points open.

7. After the ignition timing is set, recheck the point gaps. Both must still be within the proper specification (0.3–0.4 mm/0.012–0.016 in.).

If either gap is not within this value, increase or decrease it as necessary so that it is. Increase or decrease the other point gap by the same amount. Both must be within the given range.

After making any adjustment to the point gap, the timing will have to be readjusted.

If the gaps have been changed by equal amounts, it will only be necessary to adjust the timing by moving the base plate.

If proper ignition timing is not possible, replace both sets of points, since the fiber heels are probably worn.

Static Timing

1. Remove the alternator cover, points cover, and the left intake valve cover.

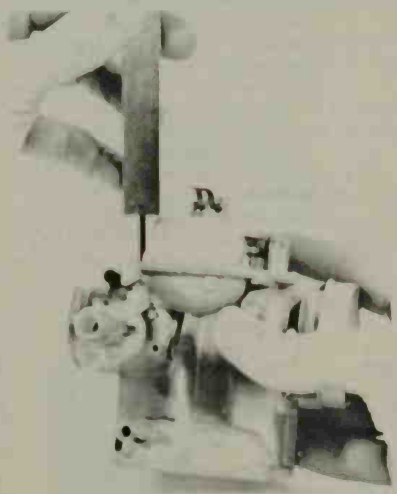
2. Remove the spark plugs and hook up the tester.

3. Turn the engine over so that the left cylinder is on the compression stroke (the left intake valve will go down and come up). Turn the engine over slowly in the normal direction of rotation (counterclockwise). At the instant in which the "LF" mark on the rotor aligns with the index mark on the stator, the points should begin to open as indicated by the reaction of the test light or the meter.

4. If the points open before the marks align, the timing is too advanced. If they open after the "LF" mark passes the index, the timing is too retarded.

5. If the timing is not correct, set the "LF" mark so that it is aligned with the index mark on the compression stroke. Loosen the two screws which secure the breaker base plate and rotate the plate until the light or meter indicates that the points have just opened. Tighten the base plate screws and recheck the timing.

6. After completing the timing for the left cylinder, connect the light or meter to the points for the right cylinder. Turn the rotor 180° counterclockwise until the "F" mark aligns with the index mark; at this point the right set of points should just open. If the timing is incorrect, align the "F" mark with the index mark and increase or decrease the point gap so that the points just open as indicated by the light or meter. Refer to steps 6 and 7 under "Dynamic Timing," above. Tighten the set screws and recheck the timing and the point gap for both cylinders. Note that both gaps must still be within specifications.

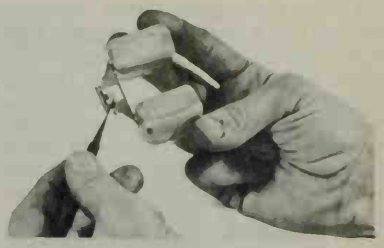


CARBURETOR

Adjusting Float Level

1. Remove the carburetor from the motorcycle.

2. Remove the float bowl. Remove the float bowl gasket.



3. Float level is defined as the measured distance from the float bowl mating surface on the carburetor body (gasket removed) to the top of the floats, when the tang of the float arm is just touching the end of the float needle. A special gauge is available to check the float level although a vernier caliper can also be used.

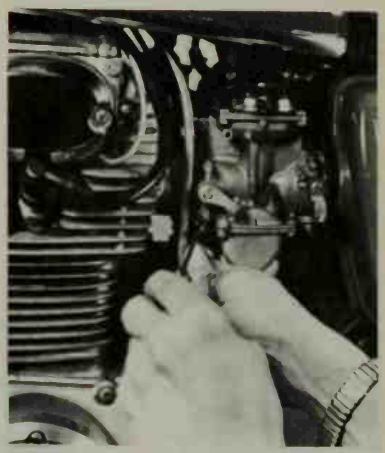
Checking float level

4. With the carburetor held at about a 45° angle, gradually lower the floats until the tang of the float arm just touches the end of the float needle. The tang should not depress the needle, but just contact it. Measure the distance from the carburetor body to the top of the floats. Compare the reading with the proper float level for your machine as given in the "Carburetor Specifications" chart.

5. If the adjustment is necessary, bend only the float arm tang to raise or lower the float level.

Bend the float tang to adjust float level

6. Float level will not be correct if the needle is worn, or if there is foreign matter on the needle seat.



Idle Speed and Mixture

NOTE: *These items must be adjusted when the engine is at operating temperature.*

350 MODELS

1. Ensure that the throttle cable adjustment is approximately correct so that the cable has enough slack to allow the throttle plates or slides (SL 350) to be fully closed.

2. Screw the pilot screw in carefully until it bottoms lightly, then turn it out the number of turns shown in the "Tune-Up Specifications" chart.

Setting the pilot screw

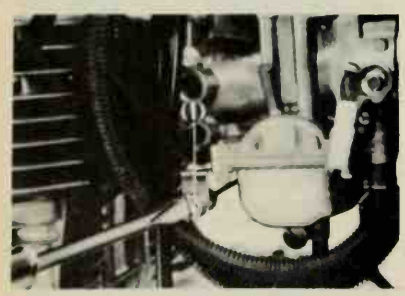
Adjusting the throttle stop screw (350)

3. Start the engine. When operating temperature is reached, unplug one spark plug lead and adjust the throttle stop screw for the other cylinder so that the engine idles as slowly as possible. Then turn the pilot screw in or out until the engine runs smoothly. It should not be necessary to vary the screw more than one half turn in either direction from the given setting.

4. Connect the spark plug lead and run the engine a few moments to allow the engine to clear out. Repeat Step 3 (above) for the other cylinder.

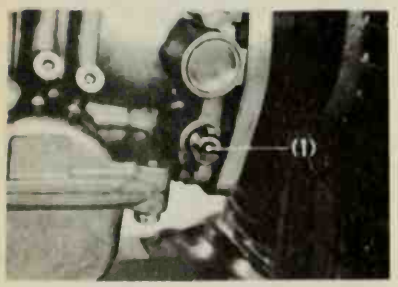
5. Connect both plug leads again and turn each throttle stop screw out by equal amounts until the proper idle is reached.

6. Check that the two carburetors are synchronized by opening and closing the throttle while watching the throttle stop screws. Both screws must begin to move at the same time when the throttle is opened. If one begins to move before the other, use the cable adjusters on the carburetors so that the movement of the stop screws is synchronized.



7. Snap the throttle open and closed several times to make sure that synchronization is maintained.

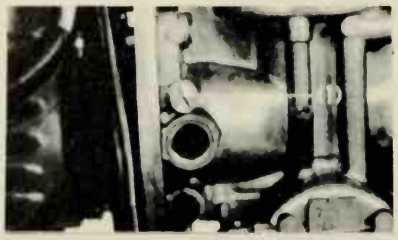
8. Adjust the throttle cable free-play using the adjuster near the twist-grip so that the throttle has 10–15° of free rotation before the stop screws begin to move.



360 MODELS

1. Turn each pilot screw in carefully until it bottoms lightly, then turn each out 1 turn. Using the throttle stop screw, set the idle at 1,200 rpm. Turning the screw in will increase the idle speed.

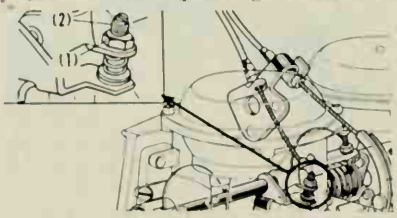
2. Turn the pilot screw for one cylinder in or out until the highest idle speed is reached. Perform this operation



Throttle stop screw (1) (360)

Pilot screw (1) (360)

for the remaining cylinder. Reset the idle speed with the throttle stop screw if necessary.



Vacuum gauge plug (1) (360)

3. If after performing the above operations the correct idle speed cannot be obtained or the exhaust pipe backpressure differs between the two cylinders, synchronize the carburetors as described below.

4. Remove the fuel tank and connect it to the carburetors with longer fuel lines. The fuel tank must be higher than the level of the carburetors. Remove the plugs from the carburetors and install vacuum gauges in their place.

5. Start the engine and note the reading on the gauges. The difference in vacuum between the two cylinders should be less than 2 cm Hg, and both should be within the range of 16–24 cm Hg.

6. If the difference in vacuum between the two carburetors is greater than 2 cm Hg, loosen the locknut on the adjusting screw and turn the adjusting screw in or out until both carburetors are within 2 cm Hg of each other. When the adjustment is complete tighten the locknut and rev the engine up a few times. Recheck the gauges and readjust if necessary.

Adjusting screw (2) and locknut (1)

7. If the carburetors cannot be adjusted so that they are within 2 cm Hg of each other or if either carburetor is out of the range of 16–24 cm Hg, check the following:

a. Air leaks around intake manifold or air cleaner;
b. Ignition timing;
c. Tappet clearance;
d. Compression pressure;
e. Spark plug gap and condition;
f. Punctured carburetor diaphragm.

8. Repeat Steps 1 and 2 to adjust the pilot screw and idle speed

ENGINE AND TRANSMISSION

NOTE: *Common service and inspection procedures for engine components such as pistons, valve assemblies, etc., are given in the "Engine Rebuilding" section under General Information. Specifications for Honda 350/360 engines are given in the charts at the end of this section.*

ENGINE REMOVAL AND INSTALLATION

350

1. Remove the oil filler cap and drain the oil. When the oil is completely drained refit the filler cap and drain plug.
2. Remove the exhaust system.
3. Open the seat and remove the battery. When disconnecting the battery always disconnect the negative terminal first, this will prevent shorting the battery to the frame when disconnecting the positive terminal.
4. Disconnect the starter motor cable (if fitted) from the solenoid.
5. Turn the fuel petcock to the off position and disconnect the fuel lines. Use two small C-clamps to pinch off the fuel balance tube and a spare piece of fuel line. Disconnect the balance tube from one side of the fuel tank, and plug the open side of the tank with the spare piece of pinched fuel line. Remove the tank from its rear mount by pulling back on the rubber strap while lifting up the rear of the tank. Pull the tank up and back to remove it from the front mounts.
6. Disconnect the alternator leads from the wiring harness at the connector. Disconnect the yellow and blue breaker point leads from their connectors.
7. Remove the rear horn mounting bolt and loosen the front bolt, tilt the horn out of the way, as shown.
8. Disconnect the tachometer cable from the engine after removing the phillips head set screw.
9. Remove the stepbar (except SL models) and gearshifter. Remove the four screws from the countershaft sprocket cover and remove the cover with the clutch cable still attached. Take care not to lose the steel ball from the clutch release mechanism when removing the cover.
10. Remove the masterlink from the drive chain. Install the masterlink on one end of the chain for safekeeping.
11. Disconnect the brake rod from the brake pedal, remove the brake pedal pivot bolt, and the brake pedal.
12. Loosen the connecting bands holding the carburetors to the intake manifold and the air cleaners. Disconnect the choke band from the right carburetor. Remove the carburetors and disconnect the throttle cables. On SL models with direct control type carburetors, place the throttle slides in a plastic bag secured with a rubber band around the cable.

Top engine mount (350)

Spacer location (CB, CL)

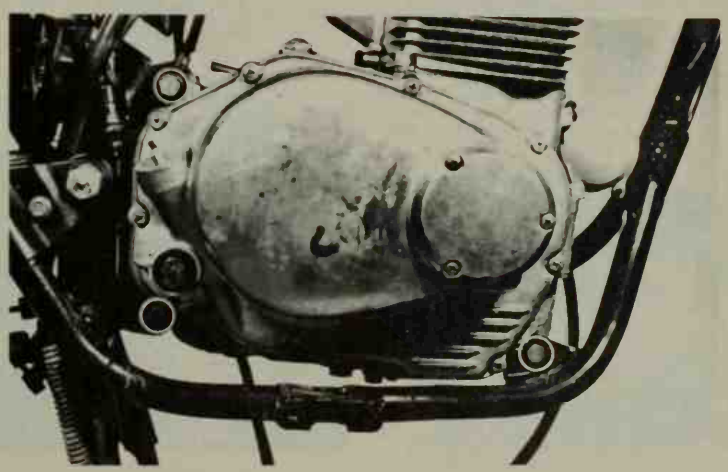
13. Disconnect the spark plug leads. Loosen the spark plugs.
14. Remove the three bolts from the top engine mount and remove the two mounting plates.
15. Remove the nuts from the lower engine mounting bolts. Remove the starter motor cable from the rear mounting bolts and remove all of the mounting bolts. Note that the battery negative cable will be completely disconnected when the nut is removed from the upper rear mount. It should be removed and placed in a safe place.
16. Remove the engine, lifting it out of the right-side of the frame.
17. Installation is the reverse of the removal procedures, however, note the following points:

a. The starter motor cable is held in place by two clamps fastened to the rear engine mounting bolts;

b. The battery negative cable is fastened to the upper rear mounting bolt on the right-side. Be sure to clean all dirt and paint from the frame so that the cable may make a good ground;

c. A spacer is fitted between the frame and the engine on the left front mount (CB, CL models);

d. When connecting the drive chain be sure that the opening in the masterlink spring clip is facing the opposite direction of chain rotation;



e. Install the mounting bolts from the right-side of the frame and the nuts from the left;

f. Check that the steel ball is still in place in the clutch release mechanism when installing the countershaft sprocket cover;

g. Adjust the throttle cables, rear brake, valve clearance, and ignition timing. Be sure that the drain plug is tightened and fill the sump with oil.

360

1. Remove the oil filler cap and drain the engine oil. When the oil has completely drained, refit the filler cap and the drain plug hand-tight.
2. Open the seat and remove the battery. When disconnecting the battery always disconnect the negative terminal first, this will prevent shorting the battery to the frame when disconnecting the positive terminal.
3. Disconnect the starter motor cable from the solenoid.
4. Turn the fuel petcock to the off

Battery negative cable (arrow) and lower engine mounting bolts

position and disconnect the fuel lines from the petcock and remove the fuel tank.

5. Disconnect the yellow and blue breaker point leads from their connectors under the fuel tank.

6. Disconnect the tachometer cable from the engine after first removing the phillips head set screw.

7. Remove the exhaust system.

8. Remove the gearshifter pinch-bolt and pull the gearshifter from the shifter shaft. Remove the four screws from the countershaft sprocket cover and remove the cover with the clutch cable attached. Take care not to lose the steel ball from inside the clutch release mechanism when the cover is removed.

9. Remove the two bolts from the countershaft sprocket. Turn the countershaft sprocket lockplate until the tabs on the inside of the lockplate line up with the slots on the countershaft, and remove the lockplate. Remove the countershaft sprocket and the chain from the countershaft.

10. Loosen the connecting bands holding the carburetors to the intake manifold and the air cleaner. Pull the carburetors straight back until they are free of the intake manifold and remove them from the left-side. Disconnect the throttle cables from the carburetors.

11. Disconnect the alternator wiring from the wiring harness at the connector between the air cleaners. Remove the spark plug leads from the spark plugs.

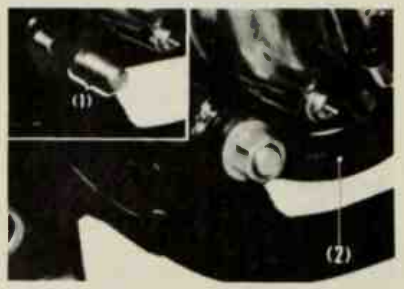
12. Disconnect the brake rod from the rear brake pedal. On CL models, remove the pinch-bolt from the pedal and pull the pedal off the shaft. On CB models, remove the bolt from the end of the pivot shaft and remove the shaft and the pedal.

13. Remove the three bolts from the upper engine mount and remove the two mounting plates.

14. Remove the two bolts from the mounting plate at the upper right mount and the through-bolt. Remove the mounting plate.

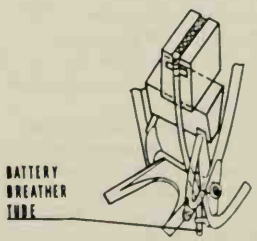
15. Remove the four front mounting bolts, three from the right-side and one from the left-side.

16. Remove the nuts from the lower rear mounting bolt and remove the bolt and the foot pegs.

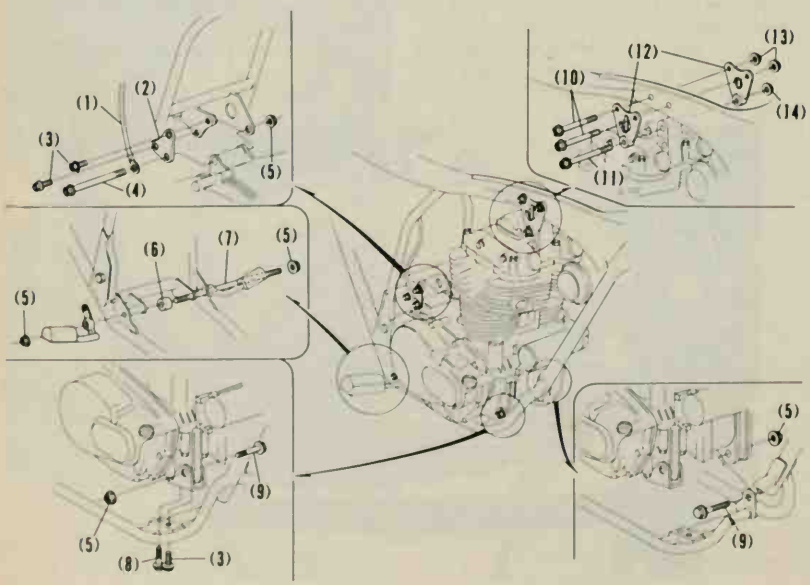


17. Remove the engine from the right-side.

18. Installation is the reverse of the removal procedures. Note the following points:



a. Install the engine in the frame from the right-side;



b. Install the mounting bolts and plates as shown;

c. The battery negative terminal is fastened to the upper rear engine mounting through-bolt. Scrape any rust or paint from the mounting plate before attaching the cable; this will ensure a good ground;

The lower mounting bolt (1) should be threaded equally into each nut; footpeg (2)

Engine mounting bolt and plate locations (360)

d. The lower rear mounting bolt should be threaded equally into each nut;

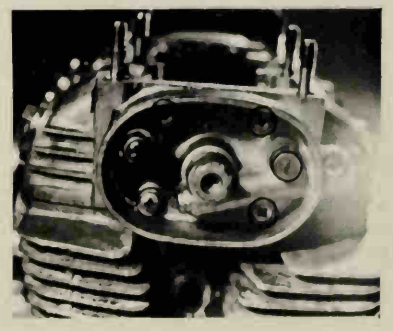
e. Connect the starter motor cable, and route the battery overflow tube as shown;

f. Before installing the countershaft sprocket cover, make sure that the steel ball is in place in the clutch release mechanism;

g. When connecting the fuel lines to the petcock, the right carburetor is connected to the rear outlet on the petcock and the left carburetor is connected to the forward outlet;

TOP END OVERHAUL

Disassembly



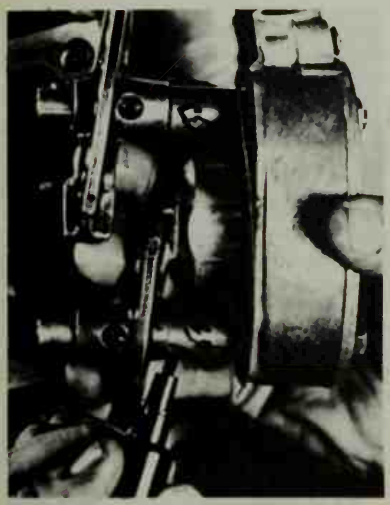
350

1. Remove the engine from the frame as described previously.

2. Remove the chrome covers from the point and tach drive housings. Remove the three phillips head securing screws from the alternator stator cover and remove the cover. Remove the spark plugs.

3. Remove the breaker plate after removing the two phillips head securing screws and disconnecting the yellow and blue leads from the wiring harness. The plate can be marked in relation to the point housing before removal for approximate setting of the ignition timing upon reassembly.

4. Remove the breaker cam bolt and washer from the left-side of the cam. Remove the spark advance unit from the left end of the camshaft; do this by looping a piece of string behind the unit and pulling it off the camshaft.



Rocker arm shaft locknuts and tach drive housing mounting screws

CAUTION: *Note that if the* point cam *is removed from the advance unit it must be installed correctly with the weights fully open; it is possible to install the point cam 180° off, making proper ignition timing impossible.*

5. Loosen the eight cylinder head cap nuts ¼ turn at a time in an "X" pattern until they are all loose, then remove them and the washers beneath them. Remove the top cover, cover gasket, breather plate, and breather plate gasket from the cylinder studs.

6. Remove the four cam chain tensioner mounting bolts and remove the cam chain tensioner and gasket.

7. Using the rotor bolt, turn the engine over until all of the valves are closed. Remove the four locknuts and washers from the eccentric rocker arm shafts (note that these are special washers). Remove the four phillips head screws from the point and tach drive housings, and remove the housings, tapping around the sides with a plastic mallet if necessary to free them. Remove and discard the gasket.

Mark the location of each rocker arm and shaft

8. Remove the rocker arm shafts and the rocker arms marking their position so that they can be installed in their original position upon reassembly.

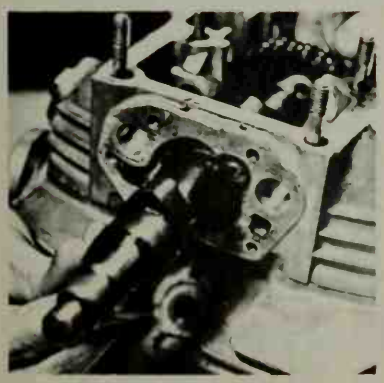
9. Temporarily install the point and tach drive housings, but do not install the mounting screws. Using the rotor bolt, turn the engine over until the "LT" mark on the rotor is approximately 10° after TDC of the exhaust stroke (the exhaust lobe of the left cylinder should be facing the front of the engine) and remove the cam sprocket alignment bolt. Turn the crankshaft 360° so that the remaining cam sprocket bolt (shouldered sprocket setting bolt) can be removed.

10. Remove the point and tach drive housings. Slip the cam out from the right-side of the cam case with the "L" mark on the cam sprocket and the alignment pin for the spark advance unit facing up. Slip a screwdriver through the sprocket to prevent it from falling through the head.

11. Remove the four phillips head screws from the cam case and remove the cam case and gasket.

12. Remove the two head set bolts located near the spark plug holes and lift the head and head gasket off. Note the location of any dowel pins.

13. To remove the cylinders, hold the cam chain up and position the pistons so that they are at the same level. Lift off the cylinders, tapping around the base of the cylinder with a plastic mallet if necessary. Do not allow the pistons to fall against the crankcase.



CAUTION: *The cam chain tensioner roller located between the cylinders is held in place with two rubber pads. Once the cylinders are removed these are easily dropped into the crankcase.*

14. Carefully remove the cylinder base gasket and lift out the rubber pads from the cam chain tensioner roller with needlenose pliers. Slip out the roller pin and remove the tensioner roller assembly.

Removing the tensioner roller assembly

15. Stuff a clean lint-free cloth into the crankcase under the pistons. Remove the circlip from the outside of each piston and push the wrist pin out from the inside. Remove the pistons and mark their location on the inside of the skirt.

Removing the camshaft

Removing a wrist pin circlip

360

The top end can be disassembled for inspection and service with the engine in the frame.

1. Open the seat and remove the fuel tank.

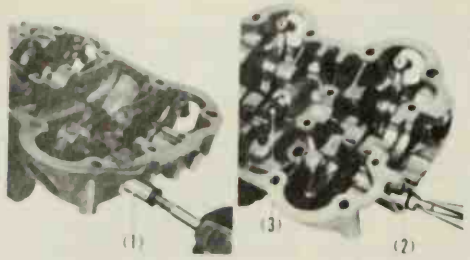
2. Remove the upper engine mounting plates after removing the three mounting bolts.

3. Remove the two phillips head screws from the point cover and remove the cover. Remove the breaker plate after removing the two securing screws and disconnecting the yellow and blue leads from the wiring harness.

4. Remove the spark advance unit from the end of the camshaft. This can be done by looping a piece of string around behind the advance unit and pulling the string. Note that the point cam is a part of the advancer unit, if the point cam is removed from the unit be sure that it is installed correctly. The point cam can be installed 180° off, making correct ignition timing impossible.

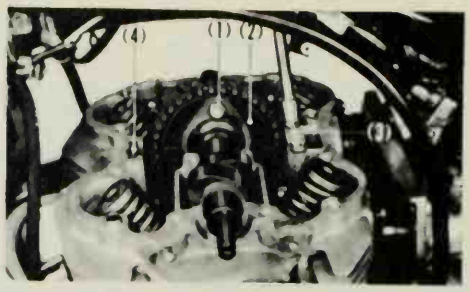
5. Remove the breather cover after removing the four mounting bolts.

6. Remove the spark plugs.



7. Disconnect the tachometer cable from the cylinder head cover after removing the phillips head set screw. Remove the tappet caps from the cylinder head cover.

8. Remove the three phillips head screws from the alternator stator cover and remove the cover. While watching the intake tappet for the left cylinder, turn the engine over with the rotor bolt until the intake tappet goes all of the way down and then rises. Continue turning the crankshaft until the "LT" mark on the rotor is 90° past the index mark on the stator. In this position the left cylinder should be 90° after top dead center (ATDC) of the compression stroke, and all of the valves should be closed.



9. Loosen the 14 cylinder head cover mounting bolts (6-6 mm, 8-8 mm) gradually and evenly in an "X" pattern until they are all loose (two are inside the breather cover), and then remove them. Remove the cylinder head cover working it out the left-side. Be sure not to lose the two dowel pins located between the cylinder head and the cylinder head cover. To inspect the rocker arms and the rocker arm shafts they will have to be removed from the cylinder head cover. To remove the rocker arm shafts from the right-side, unscrew the cap bolt from the cover and screw a 6 mm screw into the end of the shaft. Using the screw, pull the shaft out

Removing the rocker arm shafts (360)

Removing the tensioner holder (3) and tensioner slipper (4)

of the cover, the rocker arm and side spring can now be removed. To remove the rocker arm shafts from the left-side, pry out the rubber plug from the cover and pull the shafts out with a pair of needlenose pliers, remove the rocker arm and side spring.

10. Remove the cam chain tensioner holder from the top of the cylinder head. Remove the tensioner slipper.

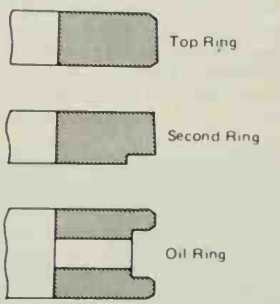
11. Using the rotor bolt, turn the engine over until one of the cam sprocket bolts is at the top of the sprocket, remove the bolt. Turn the crankshaft one complete turn (360°) and remove the remaining bolt.

12. Slip the cam chain off the sprocket and remove the cam and sprocket together. Take care not to let the thrust washers on the right-side of the cam fall into the engine. Slip a screwdriver through the chain to prevent if from falling through the head.

13. Remove the exhaust system and carburetors.

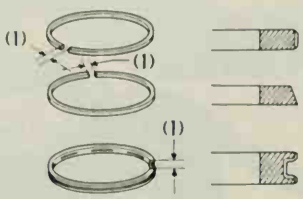
14. Remove the two 6 mm bolts located near either spark plug hole, then loosen the eight cylinder head nuts gradually and evenly in an "X" pattern until they are all loose, then remove them. Lift the head up and off the cylinder studs, tapping it around the bottom with a rubber mallet to break it loose if necessary. Remove the head gasket and the four dowel pins. If the cylinders are to remain in place, slip a screwdriver through the cam chain to prevent it from falling through the cylinders.

15. Hold the cam chain up and position the pistons so that they are the same level in the cylinders. Lift the cylinders up and off the studs. Catch the pistons as the cylinders are removed so that they do not become damaged from hitting the crankcase. Remove the cylinder base gasket and the two dowel pins and stuff a clean lint-free cloth into the crankcase around the pistons.



16. Remove the wrist pin circlip from the outside of each piston, and push the wrist pin out from the inside.

Inspection

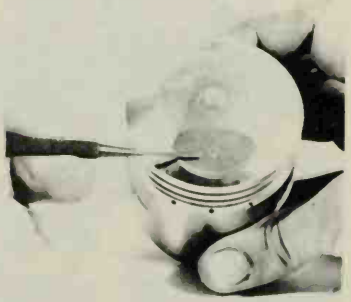


1. 350 models: The minimum outside diameter of the rocker arm shaft is 12.90 mm (0.508 in.).

2. 360 models: The rocker arm shaft-to-rocker arm clearance should not exceed 0.1 mm (0.0039 in.).

3. Before installing the rings on the piston, first note that the two compression rings are not interchangeable. The lower compression ring is wedge-shaped (360) or stepped (350).

Cross-section of 350 piston rings

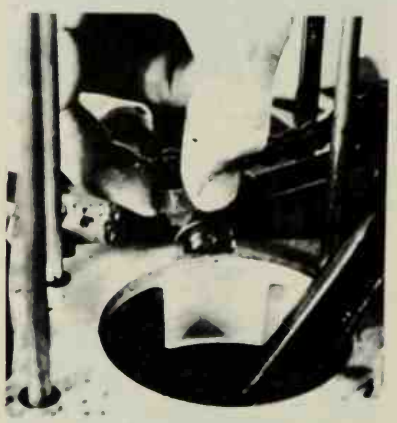


When installing the rings, space the end-gaps 120° apart (1); ring cross-sections show proper installation of 360 cc rings

Also note that rings must be installed with the manufacturer's mark (the small letter near the end-gap) facing up when the rings are in place.

Assembly

350



1. Install a new wrist pin circlip into the left-side of the right piston and into the right-side of the left piston. The arrow stamped on the piston crown must face the front of the engine (exhaust side).

The arrow on the piston crown must point toward the exhaust port (350 shown)

2. Position the piston on the connecting rod so that the wrist pin holes line up with the connecting rod small end, and install the wrist pin after coating it with oil. Place a cloth under each piston to cover the hole in the crankcase, and install the remaining circlip.

3. Install the lower cam chain roller into the cam chain, and then slip the tensioner over the cam chain and roller, then insert the roller pin through the center of the roller. Fit the tensioner assembly in place between the cylinders with the cutouts in the roller pin facing up. Apply a drop of gasket cement to the bottom of each of the rubber inserts and place an insert in each side of the roller pin.

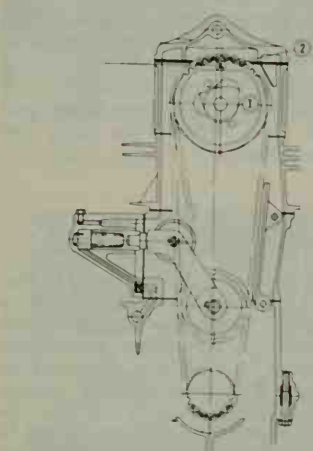
Installing the rubber roller pin inserts

4. Carefully install the cylinder base gasket, when routing the cam chain through the center of the gasket do not lift the tensioner out of place as the rubber inserts may fall into the crankcase.

5. Position the pistons at the same level. Coat the piston skirt and rings with clean motor oil, also oil the cylinder walls. Slide the cylinders down over the cylinder studs and onto the pistons while an assistant compresses the rings as they enter the bore. Make sure that the ring end-gaps are still spaced 120° apart and the two dowel pins are located to the outside front studs.

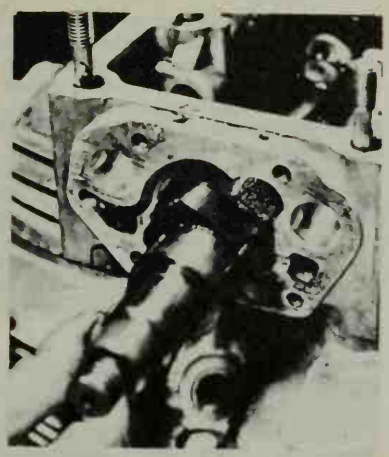
6. Using a piece of hooked wire, pull the cam chain up from between the cylinders. Install the cam chain sprocket into the cam chain so the "L" mark on the sprocket is on the left-side.

7. Make sure that the arrow on each piston is facing the front of the engine and the two dowel pins are located to the



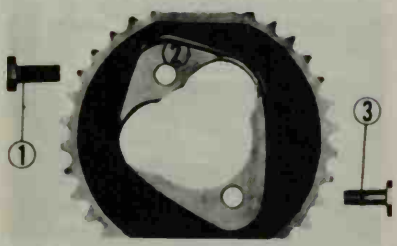
outside front studs. Install the head gasket placing a thin coat of oil on both sides of the gasket to ensure a good seal. Place the cylinder head into position and install the two 6 mm bolts, but do not tighten them to the proper torque until after the head is torqued properly.

8. Place the cam case gasket into position. Install the dowel pins on the outside rear studs and install the cam case. Tighten the four 6 mm mounting screws to 4.3–5.3 ft lbs in an "X" pattern a little at a time. Recheck the torque after the head is installed and torqued.



Installing the cam case while pulling the chain through

9. While holding the cam chain up, turn the engine over with the rotor bolt until the "LT" mark is aligned with the index mark on the stator. With the engine in this position, position the cam chain sprocket so that the "L" mark is at the top. The flat surface on the sprocket rubber damper should be parallel to the cam case mating surface.

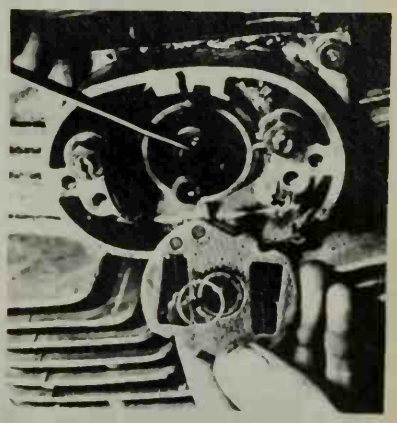


Correct valve timing: the "LT" mark on the alternator rotor is aligned with the stator index mark and the flat surface of the sprocket (1) rubber should be parallel with the upper surface of the cam case (2)

10. Slip the cam into the cam case and through the sprocket. When installing the cam, the spark advance aligning pin should be on the top of the cam. When

Install the camshaft through the right-side of the cam case

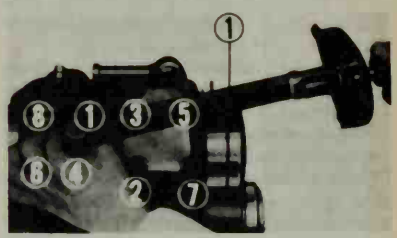
Sprocket setting bolt (1), sprocket (2), and alignment bolt (3)



the cam is in place, install the cam sprocket setting bolt. There are two different sprocket bolts, their installation must not be reversed. The sprocket setting bolt is threaded full length and should be installed in the top of the sprocket when the "L" mark is up. Hold the cam up and turn the crankshaft 360°, this will position the sprocket so that the sprocket alignment bolt may be installed (this is a shouldered bolt).

NOTE: *These bolts should be replaced with new ones once removed. They should also be coated with thread locking compound before installing them.*

11. Install the rocker arm and shafts making sure that they are installed in their original positions. The cam lobes should all be facing down for easy installation of the rockers. Install the tach drive and point housings making sure to coat the inside of the bearings before installing them on the cam. Do not use force to install the housings, hand-pressure is all that is necessary if the cam is in the right position (all lobes facing down; 90° after TDC compression stroke left cylinder).



12. With clearance between all four rocker arms and the cam, set a dial gauge to the side of the cam sprocket and measure the cam side clearance. If the clearance is greater than 1.0 mm (0.04 in.), remove one of the side housings and install thrust washers until the clearance is within the standard specification of 0.2–0.6 mm (0.008–0.024 in.). Thrust washers are available from Honda in 0.1 and 0.2 mm sizes. Again check the side clearance with the side housing installed and properly torqued. Note that the side clearance can only be measured with both housings properly torqued.

13. Install the spark advance unit, locating the pin on the camshaft to the slot in the advance unit. Install the breaker points making sure that there is a flat washer on each of the securing screws.

Engage the pin on the cam with the slot in the timing advance mechanism

14. Push the tensioner pushrod into the tensioner housing and lock it there with the set bolt. Mount the tensioner in position on the rear of the cylinders with the four mounting bolts. Release the set bolt and the tensioner will automatically adjust itself. Tighten the set bolt and the locknut.

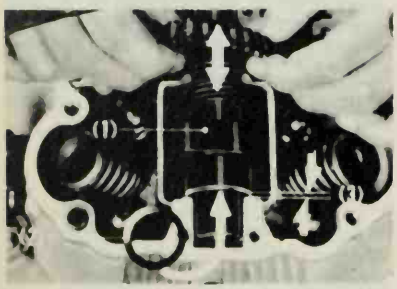
Cylinder head nut torquing sequence (350)

15. Install the breather plate gasket, breather plate, top cover gasket and top cover. Install a washer and capnut on each of the cylinder studs and tighten them gradually and evenly in an "X" pattern, starting from the inside and working out until the proper torque of 13–14.5 ft lbs is reached.

16. The remainder of assembly is in the reverse order of the removal procedures.

360

1. Install a new wrist pin circlip into the left-side of the right piston and into the right-side of the left piston. The arrow stamped into the piston crown must face the front of the engine (exhaust side).



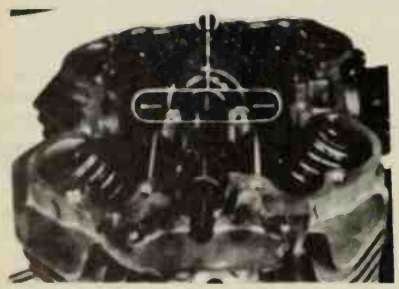
2. Position the piston over the connecting rod so that the wrist pin holes are in line with the connecting rod small end. Coat the wrist pin with clean engine oil and insert it into the piston until it is centered between the wrist pin circlip grooves. Install the remaining circlips making sure that they are firmly seated in

the grooves.

NOTE: *Placing a clean rag under the pistons when installing the circlips will prevent the circlips from falling into the crankcase in the event of a mishap.*

3. Install the cylinder base gasket and the two dowel pins. The dowel pins are located at the front of the engine around the outside cylinder studs.

4. Position the pistons at the same level and coat the piston skirt and rings with clean engine oil, also coat the cylinder walls with oil. Slide the cylinders down over the studs and onto the pistons while an assistant compresses the rings as they enter the bore. Make sure that the ring end-gaps are still spaced 120° apart and that no end-gap is located to the front or rear (90° from the wrist pin) of the cylinder.

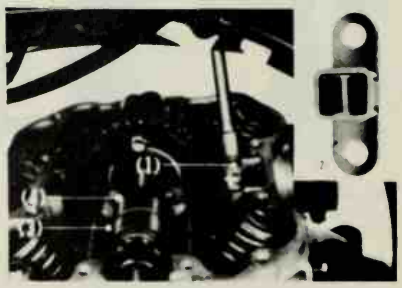


Installing camshaft thrust washers (2) to adjust side-play (3)

5. Using a hooked piece of wire, pull the cam chain out from between the cylinders.

6. Before installing the head, check the camshaft side clearance. This is done by placing the cam in the head with a dial gauge fixed to one end and measuring the amount the cam can be moved sideways. If not within the standard specification 0.07–0.3 mm (0.003–0.012 in.), correct by installing thrust washers to the right-side of the cam. Thrust washers are available in two sizes: 1.0 and 1.1 mm.

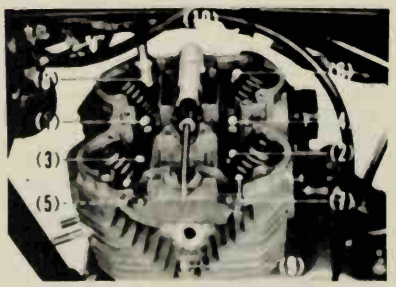
7. Install the head gasket placing a light coat of oil on each side to ensure a good seal. Install a dowel pin to each of the four outside studs, and lower the head into position while pulling the cam chain through the center of the head.



8. Hold the cam chain up and turn the crankshaft until the "LT" mark on the rotor is aligned with the index mark on the stator. With the crankshaft in this position install the cam sprocket so that the aligning marks on the sprocket are facing the left-side of the engine and are parallel to the cylinder head mating surface. Install the camshaft making sure that the thrust washers are in place on the right-side of the cam. Rotate the cam until the holes in the sprocket and cam align and install one of the securing bolts. Turn the crankshaft 360° and install the remaining sprocket securing bolt. Rotate the crankshaft 360° to the "LT" mark and check that the aligning marks on the cam sprocket are still parallel to the head mating surface.

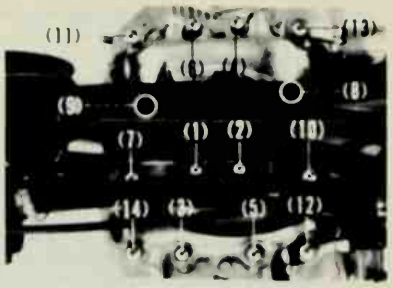
After aligning the "LT" mark on the alternator rotor, install the cam sprocket so that the aligning marks (1) are parallel to the cylinder head mating surface

NOTE: *Coat the cam bolts with thread locking compound before installing them.*



9. Install the cam chain guide to the front of the cylinder head. Install the tensioner slipper and the tensioner holder to the rear of the cylinder head. The narrow side of the holder must face the cam sprocket. Install the oil seal on the left-side of the camshaft.

Installing the cam chain tensioner holder



10. Torque the head nuts in the pattern shown in the accompanying illustration. Torque 10 mm nuts to 21.7–24.6 ft lbs and 6 mm bolts to 5.1–8.0 ft lbs. The bolts should be clean and lightly oiled to obtain accurate readings.

11. Using the rotor bolt, turn the engine over until all of the cam lobes are facing down. Pour oil over the cam, fill the oil baths with oil, and coat the cam bearings. Place a thin coat of sealing agent on the mating surface of the cylinder head cover. Take care that the sealer does not come in contact with the bearing surfaces.

Cylinder head tightening sequence

12. Install the cylinder head cover and tighten the bolts evenly and gradually, in the pattern shown in the accompanying illustration, until the proper torque is reached. Note that a cable clamp is fitted to the rear outside bolt on either side, and that bolts numbered 3, 5 in the illustration are fitted with a washer.

Cylinder head cover tightening sequence

13. Install the spark advance unit on the end of the cam noting that the pin on the cam is fitted in the slot in the advance unit. Install the contact breaker points.

14. Adjust the cam chain tension, tappet clearance, ignition timing, and point gap.

CRANKCASE COVER COMPONENTS

Right Crankcase Cover

REMOVAL AND INSTALLATION

1. Remove the oil filler cap, the drain plug, and drain the engine oil.

2. Remove the kick-starter pinch-bolt and pull the kick-starter off its shaft.

3. Remove the right exhaust pipe (CB models).

4. Remove the right footpeg (360 models).

5. Remove the cover mounting screws (12 on 360 models, 10 on 350 models) and remove the cover.

6. Installation is in the reverse order of removal, however, note the following points:

   a. Install a new cover gasket;

   b. Be sure that the two dowel pins are in place between the cover and the crankcase.

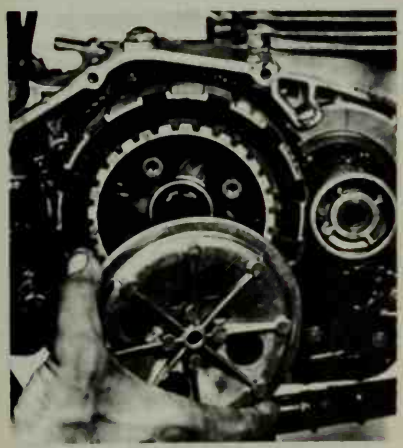
Centrifugal Oil Filter

REMOVAL AND INSTALLATION

1. Remove the snap-ring from the centrifugal oil filter. Screw a 6 mm screw or bolt into the filter cap and using the bolt pull the cap from the filter. A crankcase cover screw can be used. Remove the filter cap O-ring. Bend back the locktabs on the lockwasher and, holding the engine from turning over, unscrew the 16 mm locknut from the inside of the oil filter using the special Honda Tool No. 07916-283000 for 360 models, or Tool No. 07086-28301 for 350 models. Remove the oil filter housing, lockwasher, and spring washer.

2. To install the filter, install the filter housing on the end of the crankshaft. Install the cone shaped washer with the side marked "OUTSIDE" facing away

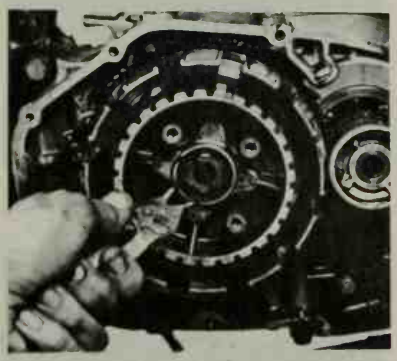
Oil filter housing (1), spring washer (2), lockwasher (3), and filter nut (4)



from the engine. Install the tabbed lockwasher, fitting the slot in the large tab over a set of splines in the filter housing. This will keep the washer from turning. Install the filter locknut onto the crankshaft and tighten with the factory tool, then bend the tabs on the washer into the slots in the filter nut.

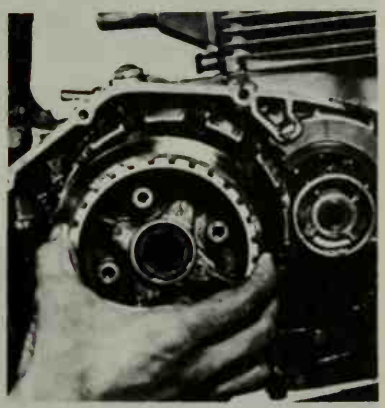
3. Install the filter cap noting that the vanes on the cap must fit into the slots in the filter housing. Secure the cap in place with a snap-ring; be sure that the snap-ring is firmly seated.

Clutch and Primary Drive



REMOVAL AND INSTALLATION

1. Remove the right crankcase cover.



Removing the clutch pressure plate

2. Remove the four clutch spring bolts, washers, and the clutch springs. Remove the clutch pressure plate, the lifter, and the pushrod.

Removing the clutch hub snap-ring

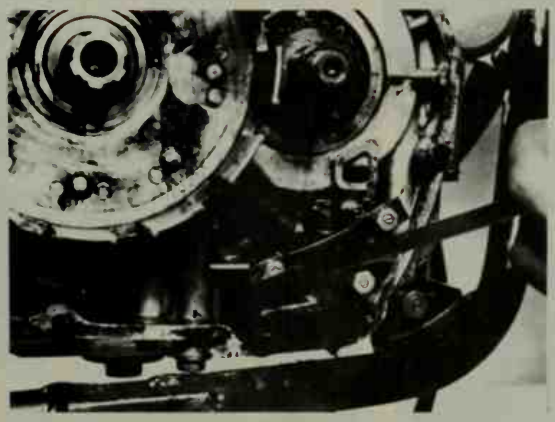
Removing the clutch hub

3. Remove the friction and steel clutch plates. Remove the 25 mm snap-ring from the center of the clutch hub and remove the hub. Remove the stop ring and remove the steel plate from the hub.

4. Remove the centrifugal oil filter as described previously. On 350 models, remove the outside primary gear. On 360 models, remove the oil pump idler gear and shaft.

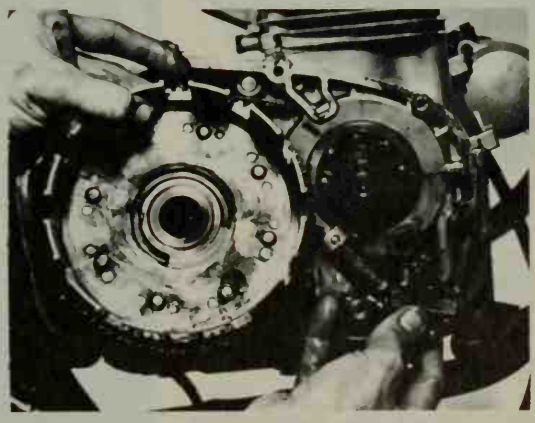
5. 350 models: Bend back the locktabs on the oil pump set plate, and remove the three mounting bolts.

6. The clutch housing can now be removed. On 350 models, the oil pump is removed with the clutch housing. The primary gear on 360 models and the inside primary gear on 350 models can now be removed.



Removing the oil pump connecting rod

On 350 models to remove the oil pump connecting rod from the clutch housing, remove the snap-ring then lift off the side washer and the connecting rod. The piston can be removed from the connecting rod by pushing the piston pin out with a small drift.



7. To install the clutch, install the primary gear to the end of the crankshaft. 350 models have two primary gears, install only the spacer and inside one at this time in that order.

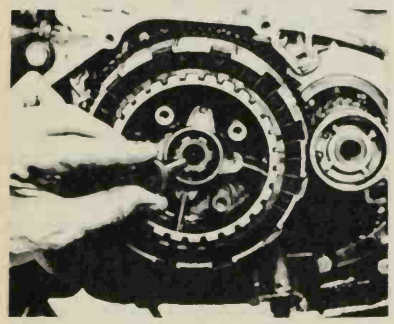
8. 350 models: Install the oil pump connecting rod to the back of the clutch housing, install the side washer, fit the tab on the side washer into the hole in the clutch housing, and secure in place with the snap-ring. Fit the oil pump piston to the connecting rod and install the piston pin. Oil the piston and insert it into the bore in the oil pump. Install the clutch housing and the oil pump at the same time. Use a new gasket behind the oil pump.

9. Install the clutch housing (and oil pump on 350 models) slip the clutch pushrod through the center of the mainshaft. On 350 models, mount the oil pump with the three mounting bolts and

Bending down the oil filter locktabs

Removing the clutch housing and oil pump together (350)

Special steel plate (1), clutch hub (2), and stop-ring (3) (360)



bend the sides of the lockplate up against the flats on the heads of the bolts. Use a new lockplate if necessary.

10. Install the special steel plate on the clutch hub and secure in place with the stop ring.

11. Install the clutch hub on the mainshaft and secure with a snap-ring. Install the clutch plates starting with a friction plate and then a steel plate and so on until all the plates are in place. The top plate should be a friction plate.

12. Fit the pressure plate lifter to the center of the clutch hub, then install the pressure plate, clutch springs, washers, and bolts. Tighten the bolts gradually and evenly in an "X" pattern until they are tight.

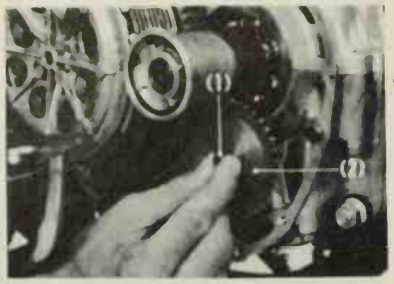
13. Install the remaining primary gear on 350 models, then install the centrifugal oil filter. On 360 models, install the oil pump idler gear and shaft.

Installing the pressure plate lifter

Oil Pump and Filter Screen

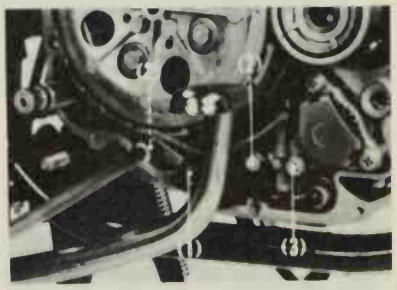
REMOVAL AND INSTALLATION

1. On 350 models, the oil pump and filter screen are removed and installed with the clutch housing. Refer to the preceding "Clutch Removal and Installation" section.



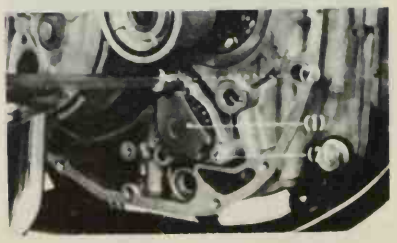
2. The following steps refer only to 360 models.

3. Remove the right crankcase cover as described previously.

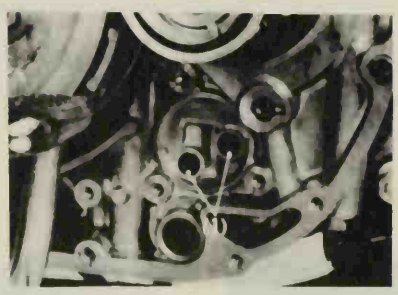


4. Remove the idler gear and shaft.

5. Remove the three mounting bolts from the oil filter screen and remove the screen. Remove the two remaining mounting bolts from the oil pump and remove the pump.



6. Complete inspection procedures for the oil pump and filter screen can be found in "Lubrication System."

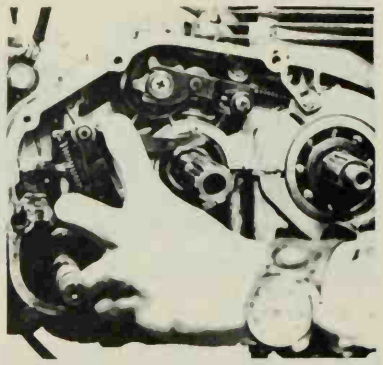


Removing the idler gear (2) and shaft (1) (360)

Oil filter screen (1) and mounting bolts (2 and 3) (360)

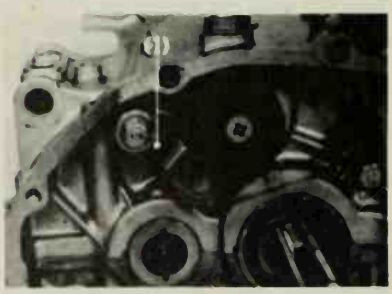
Oil pump (1) and mounting bolts (2) (360)

Oil pump O-rings (1) (360)



7. Install the oil pump and filter screen in the reverse order of removal, however, note that the two O-rings behind the pump must be in good condition. If in doubt as to their condition, replace them with new ones.

Shifter Mechanism



REMOVAL AND INSTALLATION

1. Remove the right crankcase cover and clutch as described previously.

2. Remove the shift lever pinch-bolt and pull the shift lever off the shift shaft.

Removing the shift arm

Shift drum stopper (360)

and install the mounting bolts. Do not overtighten the bolts. Coat the shift shaft with a light coat of grease and slip it through the right-side of the engine. Ensure that the fingers of the shift arm are in contact with the pins in the shift drum.

5. Refit the clutch and the right crankcase cover.

Left Crankcase Cover

REMOVAL AND INSTALLATION

1. Remove the pinch-bolt from the shift lever and pull the lever off its shaft.

2. Remove the four mounting screws from the rear cover and remove the cover.

NOTE: *Take care not to lose the steel ball from the clutch release mechanism when the cover is removed.*

3. Disconnect the clutch cable from the clutch release mechanism inside the cover.

4. Before removing the front cover, drain the engine oil. Remove three stator cover mounting screws. Remove the stator cover.

5. Disconnect the alternator wiring from the wiring harness. On 360 models, remove the carburetor to reach the connector. Disconnect the neutral switch lead from the neutral switch.

6. Remove the crankcase cover. The stator can be removed from the cover once the three mounting screws are removed.

7. To install the covers, attach the stator to the front cover with the three mounting screws. Use a new gasket under the front cover. Be sure to install the two dowel pins under each cover.

Clutch Release Mechanism

1. To remove the clutch release mechanism from the cover, unscrew the ad-

Clutch release mechanism

juster locknut from the adjuster screw. Unhook the return spring from the inside of the cover and the release mechanism can be removed from the case.

2. Clean all of the parts in solvent.

3. Inspect the adjuster screw for damaged threads. Inspect the clutch adjusting cam and release lever for wear from the ball retainer.

4. Check the dust seal for condition. If it is cracked or torn or shows signs of age, it should be replaced.

5. Clean the boss in the case with solvent.

6. Grease all parts before installing them into the case. Be sure to install the flat washer under the adjuster locknut.

Countershaft Sprocket

1. Remove the left rear crankcase cover as described previously.

2. To remove the sprocket, remove the two bolts from the sprocket and rotate the lockplate until the tabs on the plate line up with the slots in the countershaft. Remove the lockplate.

3. Either move the rear wheel forward in the swing arm or remove the masterlink from the chain, and pull the sprocket off the countershaft.

4. When refitting the sprocket, install the sprocket on the countershaft. If the masterlink has not been removed, refit the chain to the sprocket before installing the sprocket to the countershaft. Install the lockplate on the countershaft and rotate it until the holes in the sprocket line up with the holes in the lockplate. Install the two bolts and torque to 5.8–8.7 ft lbs.

Alternator and Starter Assembly

REMOVAL

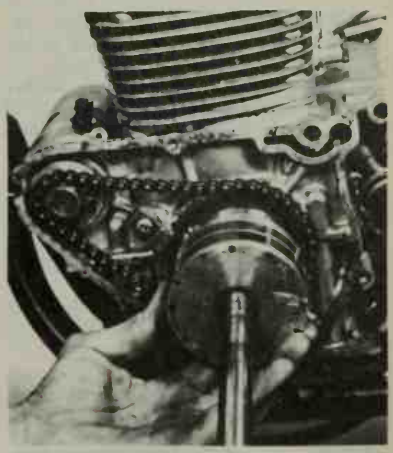
1. Remove the crankcase covers and stator as described previously.

2. Remove the rotor bolt while holding the engine from turning over.

3. Remove the alternator rotor using the factory rotor puller. In most cases the rear axle can be used in place of the puller; screw the axle into the center of the rotor until it is firmly seated. Slip a rod through the hole in the head of the axle and tap the rod with a hammer. If the rotor resists removal, use the factory puller. The starter clutch is removed with the rotor.

4. Remove the woodruff key from the taper on the crankshaft.

5. The starter clutch can be removed from the back of the rotor after removing the three phillips head screws. Remove the clutch side plate.

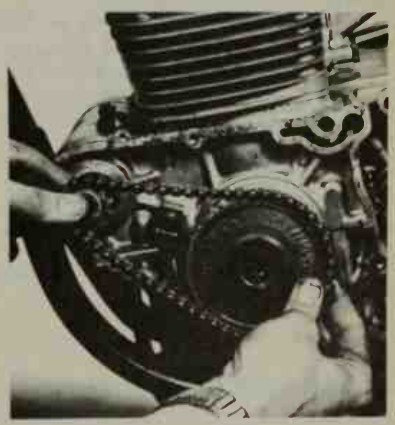


6. The starter motor chain can be removed by pulling off both sprockets and the chain at the same time.

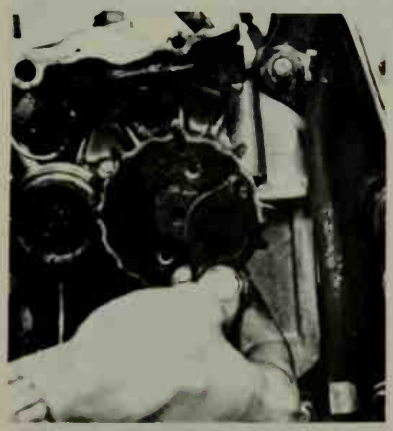
7. Unbolt the starter motor from the front of the engine, disconnecting the starter motor cable at the motor, and remove the motor tapping the shaft lightly with a plastic mallet if necessary.

INSPECTION

1. For further inspection of the alternator rotor, stator, and starting motor, refer to "Electrical System."



2. Check that the rollers in the starter clutch are free to move. Also check that they all have the same amount of spring tension on them. If any spring feels weak in relation to the others, replace it by removing the roller, spring cap, and spring. Replace the spring and install the cap and roller.



Removing the rotor with the rear axle

Check condition of the starter clutch and rollers

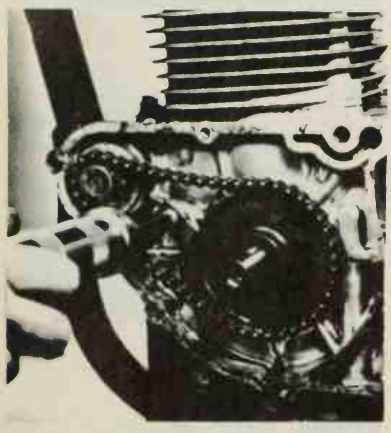
Removing the starter sprockets and chain

Removing the sprocket lockplate

Removing the rotor bolt

Starter clutch components

3. Inspect the clutch housing for any cracks. If found defective, it must be replaced.



4. Inspect the surface of the starter sprocket where the rollers contact it. If badly scored, the sprocket and the rollers should be replaced.

5. Inspect the condition of the sprocket teeth. If they are hooked or appear to be worn badly, replace both sprockets and the chain.

INSTALLATION

1. Mount the starter motor on the front of the engine with the two mounting bolts.

2. Install the starter motor chain and the two sprockets at the same time. Install the starter sprocket setting plate.

Be sure that the starter sprocket set plate is secured

3. Mount the starter clutch on the rotor with the three screws. Be sure to install the side plate between the rotor and the clutch.

4. Install the woodruff key in the crankshaft and install the rotor lining up the slot in the rotor with the key in the crankshaft. Draw the rotor down on the crankshaft with the rotor bolt, never strike the rotor as this may affect the magnets.

5. Install the stator in the crankcase cover, then install the cover using a new gasket. Check that the rotor does not come in contact with the stator as the engine turns over. Install the stator cover and the rear cover.

CRANKCASE COMPONENTS

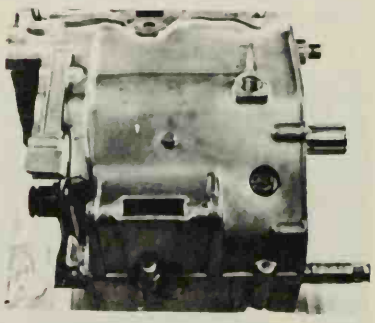
To service the kick-starter, transmission, or the crankshaft, the crankcases will have to be separated. To service the kick-starter and transmission, the left and right crankcase covers and the components beneath them will have to be removed. Service to the crankshaft also necessitates the disassembly of the top end as the cam chain must be removed with the crankshaft.

Splitting the Crankcases

1. Remove the engine from the frame.

2. If the crankshaft is to be serviced, disassemble the top end as outlined previously.

3. Remove the right and left crankcase covers and the components beneath them.



NOTE: *Loosen the oil filter nut and the rotor bolt before removing the clutch.*

4. Remove the neutral stop bolt from the upper case after bending back the locktab. Remove the spring and ball beneath the bolt.

5. Remove the crankcase bolt(s) from the upper crankcase (1 on 360 models, 2 on 350 models). Turn the engine upside down and remove the remaining crankcase bolts from the lower crankcase. Remove the lower crankcase half, tapping around the mating surface with a plastic mallet to free the case half, if stuck. The crankshaft and the transmission will remain in the upper half.

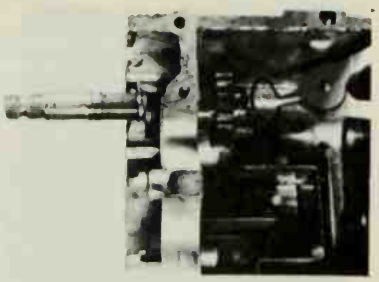
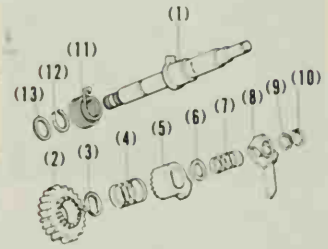
Kick-Starter

REMOVAL



1. Split the crankcases as described previously.

2. Remove the washer, circlip, and return spring from the kick-starter shaft on the outside of the lower crankcase.



3. Remove the circlip from the inside of the shaft and remove the components from the shaft. Slip the shaft out of the case.

INSTALLATION

1. Install the shaft into the lower crankcase half. Install the components on the shaft as shown in the accompanying illustration. Hold the shaft so that the stop on the shaft is against the stop in the lower crankcase when installing the internal components. Be sure that the ratchet guide plate (360 models) or the friction spring (350 models) is seated properly in the crankcase.

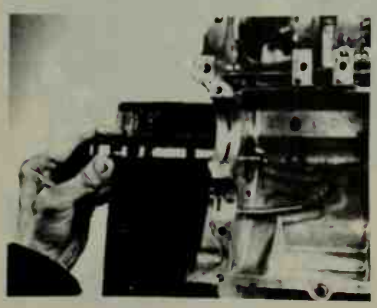
Transmission

REMOVAL

1. Split the crankcases as described previously. The transmission shafts can be lifted out of the top case.

2. 350 models: Remove the neutral switch rotor and the drum stopper from the shift drum. Remove the guide pin clips and the guide pins from the shift forks. Mark the location of each shift fork (left, center, and right) and slide the shift drum out of the case from the right-side.



3. 360 models: Remove the shift drum stopper and stopper spring. Remove the shift fork guide shaft after marking the location of the two shift forks (left or right), remove the forks taking care not to lose their guide pins. Remove the guide pin clip and guide pin from the remaining shift fork and slide the drum out the right-side of the case.

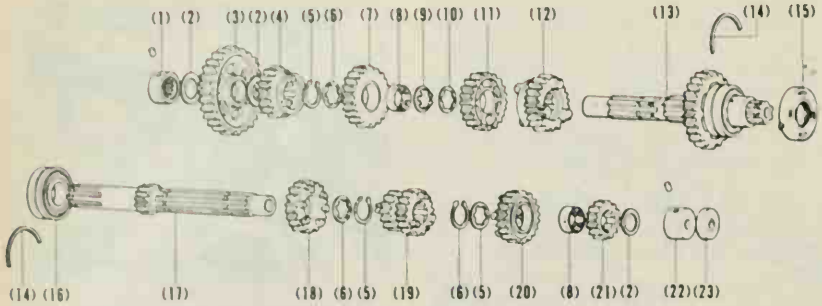
Removing the shift drum

4. The transmission gears can be removed from their shafts after removing the circlips which secure them. All components should be carefully laid out in the order in which they are removed so that they can be installed in their proper locations.

INSTALLATION

1. Slip the shift drum into the upper crankcase; as the drum enters the case, install the shift fork(s). Be sure that the fork(s) are installed in the same position from which they were removed. Install the neutral switch to the end of the shift drum.



2. Position the shift drum in the neutral position (as seen by the neutral switch) and install the neutral stopper ball, spring, lockplate, and bolt. Bend the lockplate up against the flat on the head of the bolt.

3. 360 models: Install the shift fork shaft, inserting it through the shift forks as it enters the case. Install the guide pins and check that they fit into the grooves in the shift drum.

4. Assemble the mainshaft and the countershaft as shown in the accompanying illustration. Install the transmission shafts in the upper case. Be sure that the shift forks are fitted to the proper gears.

Be sure that the bearings are fitted to the set ring or the locating pins. When properly fitted the bearings should sit flush in the case.

5. The remainder of assembly is in the reverse order of removal.

Crankshaft

REMOVAL

1. Remove the top end and split the cases as described previously.

2. 360 models: Remove the cam chain tensioner arm and lift out the crankshaft and cam chain together.

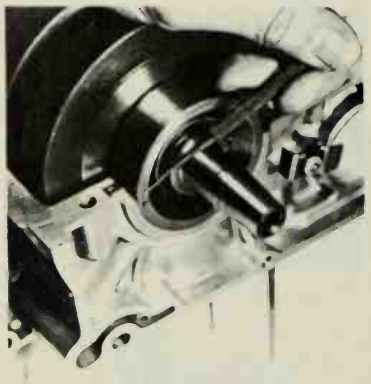
Cam chain tensioner arm (1) (360)

3. 350 models: Loosen the four main bearing cap bolts gradually and evenly until they are all loose and then remove them. Lift the crankshaft and cam chain out of the case together.

CAUTION: *Do not lose the main bearing locating pins when the crankshaft is removed.*

INSPECTION

1. Mount the crankshaft center main bearings in a set of V-blocks, and measure the run-out of the crankshaft with a dial gauge. Measurements should be taken at either end of the crankshaft and on each of the flywheels. If the run-out exceeds the service limit, the crankshaft should be replaced.



2. With the crankshaft supported at both ends, mount a dial gauge to the top of each main bearing in turn. Attempt to move the outer race up and down. The measurement on the dial gauge is the total radial clearance. If the clearance exceeds the service limit, the crankshaft should be replaced.

3. With the crankshaft firmly supported, fix a dial gauge to the bottom of the connecting rod, and measure the up and down play. The dial gauge will indicate the amount of radial clearance of the rod bearing. If the clearance exceeds the service limit, the crankshaft should be replaced.

4. Using a feeler gauge, measure the side clearance of the connecting rod. If the side clearance is beyond the service limit, replace the crankshaft.

5. With an inside micrometer, measure the bore of the connecting rod small end. If the bore is found to exceed the service limit, the connecting rod and the crankshaft should be replaced.

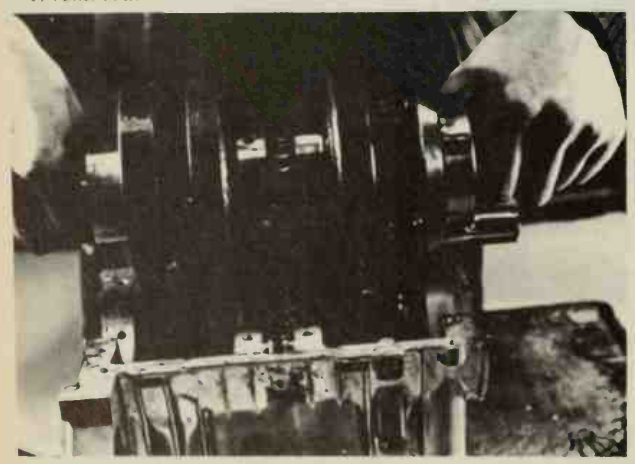
6. Rotate each of the main bearings. They should be smooth and silent. If rough or noisy, they should be replaced.

Seat the bearing locating pins into the cut-out in the case

INSTALLATION

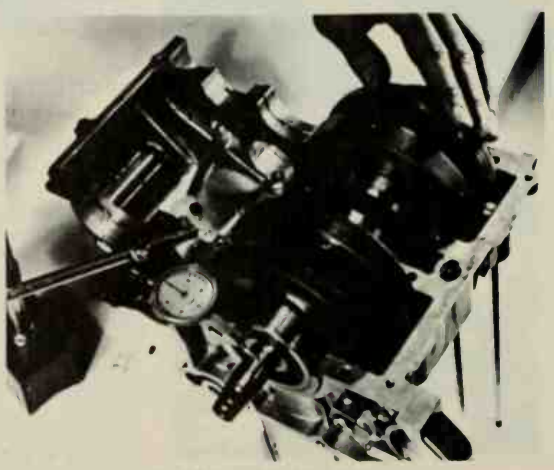
1. Fit the cam chain to the sprocket on the crankshaft.

2. Fit the crankshaft into place. Be sure that the bearing locating pins are properly seated in the upper crankcase half.



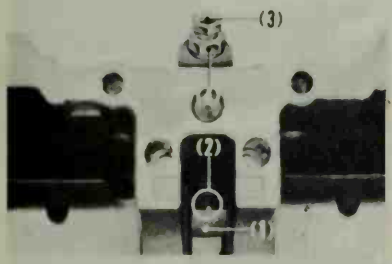
3. 360 models: Install the cam chain tensioner arm.

4. Install the main bearing cap (350) and tighten the four bolts gradually and evenly in an "X" pattern until the proper torque of 15.9–17.4 ft lbs is reached.



5. Assemble the crankcases and the top end.

360 Cam Chain Tensioner



The cam chain tensioner can be removed from the lower case by loosening the setting bolt and pulling the tensioner push bar and springs from the inside. When installing the tensioner push bar, the mark on the pad must face up. Push the push bar in to compress the springs and tighten the setting bolt.

Removing the crankshaft

Checking crankshaft run-out

Mark (2) on tensioner push bar (1) must face upward (360)

Assembling the Crankcases

1. The crankcase mating surface must be clean and free of any scratches. Minor repairs can be made with an oilstone.

2. Apply a thin coat of sealing compound to the crankcase mating surface. Be careful not to get any of the sealer on the bearings or inside surface of the crankcase.

3. Install the lower case. Make sure that the cases mate properly before installing the crankcase bolts. If they do not, check that all of the bearing locating pins are in place.

4. Install the crankcase bolts and tighten them evenly and gradually in an "X" pattern, starting from the inside and working out.

5. Install the crankcase cover components and the top end as described previously.

LUBRICATION SYSTEM

CENTRIFUGAL OIL FILTER

Removal

1. Remove the right crankcase cover.

2. Remove the snap-ring from the filter cap. Screw a 6 mm screw into the center of the cap and, using the screw, pull off the cap.

3. Hold the crankshaft from turning by placing the transmission in gear and applying the rear brake. Bend back the tabs on the lockwasher and remove the special 16 mm locknut using the factory tool (Tool No. 07916-2830000). Remove the tabbed lockwasher, and the filter housing.

Inspection

1. Clean all parts in clean solvent and allow to dry.

2. Inspect the snap-ring. It should be replaced if it is distorted or is a loose fit in the filter housing.

3. Inspect the filter cap O-ring. If it is deformed, torn, or cracked, it must be replaced.

4. Check the 16 mm locknut for condition. If the slots on the outside of the nut are badly damaged or the threads are chipped or stripped, the nut should be re-

placed.

5. Check the condition of the tabs on the lockwasher, if they are weak or missing, the washer must be replaced.

6. Inspect the condition of the cone-shaped washer. If the washer appears to be flat, it should be replaced.

Installation

1. Install the filter housing on the crankshaft, then install the cone-shaped washer, lockwasher, and locknut.

NOTE: *On 360 models and late model 350s, one side of the cone-shaped washer is marked "OUTSIDE." This side must face away from the engine. If the washer is not marked, the convex side should face away from the engine. It is recommended that this washer be replaced with a new one whenever it is removed. When installing the tab lockwasher, the slot in the large tab must fit over the splines inside the filter housing.*

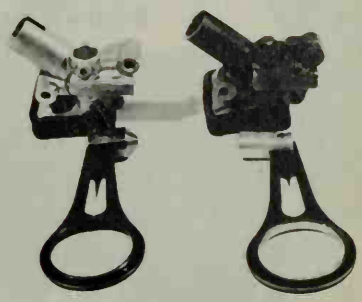
When installing the locknut, be sure that the chamfered side is facing the engine.

2. Tighten the locknut to 32.6–39.7 ft lbs for 360 models and 21.7–23.1 ft lbs for 350 models. Bend the tabs on the lockwasher into the slots in the filter nut.

3. Install the filter cap and O-ring. Be sure that the vanes of the filter cap are fitted into the slots in the filter housing. Be sure that the circlip is firmly seated.

OIL PUMP AND FILTER SCREEN

350 Models



On 350 models, the oil pump and filter screen are removed and installed with the clutch housing. Refer to the "Engine and Transmission" section.

INSPECTION

NOTE: *CB/CL350K3,K4 and SL350K1,K2 were equipped with a larger oil pump than the early models. A new pump assembly can be installed on the early models to provide better lubrication. However, if this is done, be sure to install new crankcase cover gaskets, as they were also modified. The new pump can be identified by the alloy pump body and steel piston. The*

Early and late model oil pumps

early pump body was a steel casting with an alloy piston. Note that if this modification is made the entire pump assembly must be changed.

1. Inspect the bore in the oil pump. If it is scored, the pump housing and piston should be replaced.

2. Check the condition of the pump piston. If it is scored, it should be replaced.

Check the pump piston for scoring (350)

3. CB/CL350,K1,K2/SL350: If a micrometer is available, measure the diameter of the pump piston. If found to be less than 15.930 mm (0.627 in.), the piston should be replaced.

4. CB/CL350,K1,K2/SL350: With an inside micrometer, measure the pump bore if found to be larger than 16.1 mm (0.634 in.), the pump housing and piston should be replaced.

5. Remove the suction valve bolt from the top of the pump (if fitted), and the steel ball beneath it. If the ball shows signs of wear, the pump should be replaced.

6. Remove the filter screen from the bottom of the pump and wash in clean solvent. Inspect the screen for any puncture marks. If the screen mesh is broken to any extent, the screen must be replaced.

7. Check the oil pump gasket for condition. If defective in any way, it must be replaced. It is recommended that this gasket be replaced regardless of apparent condition.

8. Inspect the condition of the mounting bolt lockplate and replace it if the tabs are fatigued.

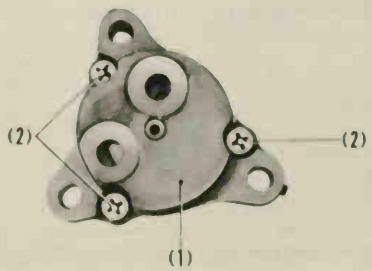
REMOVAL AND INSTALLATION

1. Remove the right crankcase cover. Refer to Chapter 4 if necessary.
2. Remove the idler gear and shaft.
3. Remove the three mounting bolts from the oil filter screen, and remove the screen. Remove the two remaining mounting bolts from the oil pump and remove the pump.
4. Install the oil pump and filter in the reverse order of removal, however, note that the two O-rings behind the pump must be in good condition. If in doubt as to their condition, replace them with new ones.



DISASSEMBLY

To disassemble the pump, remove the three phillips head screws from the rear of the pump and pull the pump halves apart.

NOTE: *It is not recommended that the pump be disassembled. If the pump is suspected of being defective, it should be replaced as a unit rather than making an effort to repair it.*

INSPECTION

1. Inspect the condition of the oil pump drive gear and idler gear. If any teeth are chipped, broken, or missing, replace the gears and inspect the primary gear for the same damage.
2. Measure the clearance between the two rotors. If the clearance exceeds the service limit, replace the pump.
3. Measure the side clearance of the rotors. If the side clearance exceeds the service limit given at the end of this chapter, replace the pump.

Disassemble the pump (1) by removing the three screws (2) (360)

FUEL SYSTEM

CARBURETOR

For an operational theory, general inspection procedures and a carburetor troubleshooting chart, refer to the "Carburetor" section under "General Information."

Direct-Control Type

REMOVAL AND INSTALLATION

1. Unscrew the carburetor cap and pull the throttle slide assembly out of the carburetor. If the slide assembly is to be disassembled, see the procedure below. If not, place a small plastic bag around the assembly to keep dirt out, and place it out of the way. Note that mishandling the assembly may necessitate replacement of the slide or needle.
2. Turn the fuel supply off at the petcock, and disconnect the fuel line from the carburetor.
3. Remove the float bowl drain plug, and drain off any gas in the float bowl. Disconnect any overflow or breather tubes.
4. Loosen the intake manifold and air cleaner connecting bands. Remove the carburetor.
5. Installation is in the reverse order of the above, but the following points should be noted:
   a. Lubricate the throttle slide if desired with a molybdenum or graphite lubricant. Insert it into the carburetor with the slide cutaway facing the air cleaner. Be sure that the slot in the

slide is engaged with the tab in the carburetor body;

b. Be sure that the slide goes in easily, and especially that the needle enters the needle jet. Do not push or force the slide into place. If resistance is noted, it is probable that the needle is cocked to one side and is not entering the needle jet;

c. Tighten the carburetor cap and check throttle operation. The slide must move freely up and down. The throttle return spring must have enough tension to snap the slide to its fully closed position if the throttle is opened and released;

d. Connect the fuel line from the right carburetor to the rear outlet on the petcock, and the fuel line from the left carburetor to the front outlet on the petcock. Secure the fuel lines in place with a spring clip;

e. Turn the fuel on and check for leaks. Start the engine and check for air leaks around the intake manifold and the air cleaner.

DISASSEMBLY

1. If disassembly of the throttle slide components is desired, compress the return spring against the carburetor cap, disengage the cable from the slide, take out the spring clip, needle and clip.

2. With the carburetor upside down, flip up the retainer and separate the float bowl from the carburetor body. Do so carefully to avoid damage to the float.

3. Push out the float pivot pin with a small drift, and remove the float. Remove the float needle from its seat. Unscrew the seat itself.

4. Using a small screwdriver, remove the main jet, pilot jet, pilot air screw, and throttle stop screw.

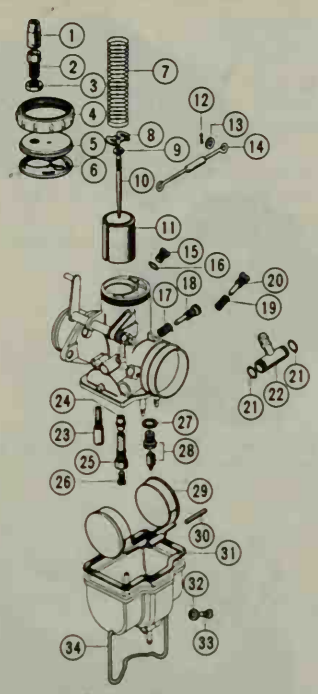
5. Unscrew the main jet holder using the correct size wrench. The needle jet can now be removed from above the main jet holder.

ASSEMBLY

Assembly is basically the reverse of the disassembly procedures, but note the following points:

1. Float bowl gaskets and jet O-rings should always be replaced with new ones. Other O-rings and fiber gaskets should be carefully inspected and replaced if less than perfect in condition. Check O-rings for tears and cracks; fiber gaskets for a crushed condition.

2. Exercise care when installing jets, they are made of soft brass and are easily damaged if overtightened. Install the needle jet, main jet holder, main jet, pilot jet, and float needle seat.



3. Install the float needle into its seat. Hold the floats in place and install the pivot pin. Install the float bowl.

4. Assemble the throttle slide.

5. Install the pilot air screw, turning it in until lightly seated, then backing it out the proper number of turns as listed in the chart at the end of this section.

6. After completing assembly, install the carburetor on its manifold.

7. Check for fuel or air leaks; make final adjustments to the throttle stop and pilot air screws.

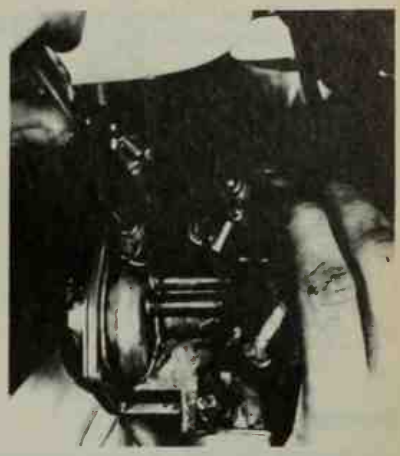
Constant-Velocity Type

REMOVAL AND INSTALLATION

350 Models

1. Turn off the fuel supply at the petcock and drain the float bowls. Disconnect the fuel lines at the petcock. Remove the fuel tank.

2. CL Models: Remove the exhaust system.



3. Remove the plastic sidecovers and the air cleaners.

4. Loosen the connecting bands which hold the carburetors to the intake manifold. Remove the left carburetor from the intake manifold and loosen the choke band pinch-bolt, and slip the band off the shaft. Remove the cable stay and disconnect the cable from the throttle lever. Remove the right carburetor and disconnect the throttle cable in the same manner.

5. Installation is in the reverse order of the above, however, note the following points:

a. Connect the throttle cables before mounting the carburetors;

b. Mount the right carburetor first, then connect the choke band as the left carburetor is installed;

Removing the cable adjuster bracket (350)

c. Connect the fuel line from the right carburetor to the rear outlet on the petcock, and the fuel line from the left carburetor to the front outlet. Secure the fuel lines in place with a spring clip;

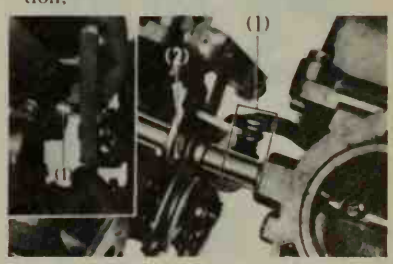
d. Turn the fuel on and check for leaks. Start the engine and check for air leaks around the intake manifold and air cleaner.

360 Models

1. Turn the fuel supply off at the petcock and drain the float bowls. Disconnect the fuel lines at the petcock and remove the fuel tank.

2. CL Models: Remove the exhaust system.

3. Loosen the connecting bands which secure the carburetors to the intake manifold and air cleaner. Pull the carburetors back toward the air cleaners until they are free of the intake manifold, then remove them by lowering them out from the left-side.



4. Disconnect the throttle cables from the cable stay. Loosen the choke band pinch-bolt and remove the choke band from the left carburetor.

5. Remove the carburetors from the mounting plate after removing the four mounting screws.

6. Installation is in the reverse order of the above, but note the following points:

a. Connect the choke band to both carburetors, tighten the pinch-bolt and bend the locktab up against the nut on the pinch-bolt;

b. Set the throttle lever to the stop screw and install the coil spring as shown in the accompanying illustration;

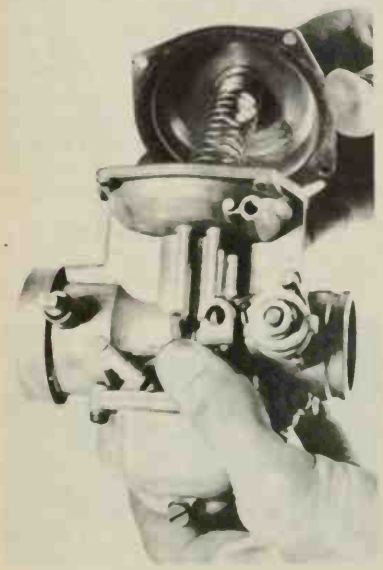
Set the throttle lever to the stop screw (1) and install the spring (2)

e. Mount the carburetors on the mounting plate with the four mounting screws;

d. Connect the throttle cables with the throttles fully closed. The closing cable is connected to the lower cable stay and the opening cable is connected to the top cable stay. Mount the carburetor assembly on the engine. Adjust the cables and secure them in place with the locknuts;

e. Connect the fuel lines to the petcock. The right carburetor is connected to the rear outlet on the petcock, the left carburetor is connected to the front outlet.

DISASSEMBLY (ALL MODELS)



1. Remove the four top cover screws and remove the top cover. Very carefully lift out the return spring and the throttle slide. If the needle is to be removed from the slide, unscrew the needle holder (360 models) or remove the spring retainer (350 models), and remove the needle.

2. Turn the carburetor upside down and remove the four float bowl screws and carefully remove the float bowl.

3. Remove the primary and secondary main jets. On 350 models, these are held in place with a retainer, while on 360 models, they unscrew.

4. Using a small drift, push out the float pivot pin and remove the float. Note that on 360 models, the float needle is removed with the float; on 350 models, the float needle can be lifted from the needle seat.

5. 360 models: Using a small wrench, unscrew the jet holder from the carburetor body, and push the needle jet out from the inside of the carburetor. The main nozzle located in front of the needle jet can also be pushed out of the carburetor body.

7. 350 models: Using a small wooden dowel, push the needle jet and main nozzle out of the carburetor.

8. Remove the phillips head set screw from the float needle seat stay and remove the needle seat by lifting it out.

9. Unscrew the pilot screw.

ASSEMBLY (ALL MODELS)

Assembly is basically the reverse of the disassembly procedures, but note the following points:

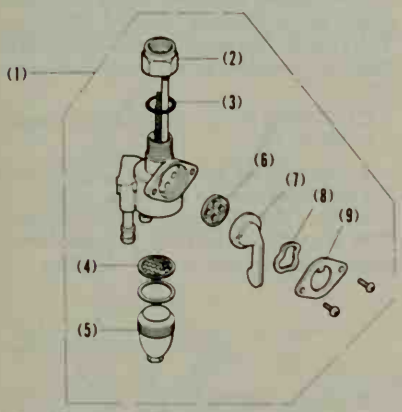
1. Float bowl gaskets and jet O-rings should always be replaced with new ones. Other O-rings and fiber gaskets should be carefully inspected and replaced if less than perfect in condition. Check O-rings for tears and cracks; fiber gaskets for a crushed condition.

2. Exercise care when installing jets, they are made of soft brass and are easily damaged.

3. Install the pilot screw, turning it in until lightly seated, then back it out the proper number of turns as listed in the chart at the end of this section.

4. Fit the tab on the diaphragm into the slot in the body.

5. Tighten the float bowl and top cover screws evenly and in an "X" pattern in order to prevent distortion.



FUEL PETCOCK AND LINES

Cleaning

1. Unscrew and remove the sediment bowl, take out the O-ring, and filter screen.

2. Clean the metal parts in solvent. Check that the filter screen is not punctured, and that the O-ring is not torn or otherwise damaged.

3. Run a little gas through the petcock to flush out any dirt. Catch the gas in a suitable container. Turning the petcock to "Reserve" for a few seconds should remove the better part of any water or dirt in the bottom of the fuel tank.

4. Check petcock operation in all positions. There must be no fuel flow when the petcock lever is turned to the "Stop" position.

5. Install the filter screen, O-ring, and sediment bowl in that order. Check for leaks before operating the motorcycle.

Disassembly

At somewhat extended intervals, the petcock should be removed from the fuel tank and cleaned.

1. Drain the fuel tank completely. Disconnect the fuel lines from the petcock. Remove the sediment bowl, O-ring, and filter screen.

2. Unscrew the nut which holds the petcock to the fuel tank, and remove the petcock.

3. Remove the two screws from the fuel lever setting plate, and remove the setting plate, lever spring, lever, and gasket.

Assembly

1. Install the fuel valve gasket, lever, lever spring, and setting plate. Secure with the two screws.

2. Be sure that the petcock O-ring or gasket is in place and install the petcock on the fuel tank. Install the sediment bowl filter screen, O-ring, and sediment bowl.

3. Be sure that the fuel lines are firmly secured at their connections and the safety circlips are in place.

ELECTRICAL SYSTEM

IGNITION CIRCUIT

1. Troubleshooting the ignition system is made somewhat easier by the fact that the components for the two cylinders are completely independent.

2. If there is a no-spark condition at *both* cylinders, the trouble will be in the battery, fuse, or wiring connections. Check the 15A fuse (located near the battery) first. If this fuse is blown, none of the electrical components will function.

If the fuse is satisfactory, check the battery state-of-charge. Although a low battery may not operate the electric starter, it does not require a very high state-of-charge to spark the plugs, turning the engine over with the kick-starter.

Check the battery terminal connections, then the ignition circuit connections, ignition switch, etc.

3. In the event of hard starting, misfiring, or cutting out, first check the carburetors. Be sure that the fault is electrical before replacing any components. Be sure that all connections are clean, dry, and tight. Wiring plugs and connectors often accumulate dirt or water, and sometimes work loose. Check these first, then proceed as follows:

4. In the event of the above troubles, or a no-spark condition at one cylinder, the plug, plug cap, lead, coil, condenser, or points for that cylinder may be defective.

5. Remove the spark plug, clean it thoroughly, or replace it with a new one; gap the plug to 0.7–0.8 mm (0.028–0.032 in.). Connect it to its cap, and ground it against the cylinder head. Kick the engine over briskly. The spark produced should be thick and blue.

6. If there is no spark, or if the spark is weak and yellow, repeat the test using a piece of metal, such as a nail, inserted into the spark plug cap and held about ⅛

in. away from the cylinder. If the spark is healthy, the problem was the spark plug; if not, check the condition of the points. Inspect, clean, and gap the points or replace them if they are badly pitted or worn. If excessive arcing or sparking at the points is noted while the machine is running, the problem may be the condenser. A defective condenser will also cause new points to wear out quickly.

If new points have just been installed, a no-spark condition can be caused by damaged or improperly installed insulating washers on the points wire terminal.

7. If the problem is not in the points or the spark plug, the spark plug cap should be checked. Noise suppressor caps are fitted, which are designed to eliminate radio interference and provide a hotter spark by means of a resistor in the cap. Sometimes the resistor breaks down, and the cap then becomes an open circuit. Remove the cap from the spark plug lead, and ground the end of the lead against the cylinder head. If a fat, blue spark is produced when the engine is kicked over, the problem was the cap. Replace it with a new one.

8. If the cap checks out okay, carefully inspect the cable itself. Check for dirt or grease, cuts or cracks in the insulation, moisture, etc. If the lead is damaged, it must be replaced. This also involves replacing the coil.

9. If the trouble has not been pinpointed, the ignition coil windings should be checked for continuity, using an ohmmeter.

a. Disconnect the two low-tension coil leads (blue or yellow and black/white) and check for continuity between them. This is a check of the primary winding. If there is no continuity, replace the coil;

b. Check for continuity across the coil's blue or yellow low-tension lead and the high-tension (spark plug) lead. Resistance may be very high, but continuity must exist. This checks the secondary winding.

Even if continuity is present in the coil windings, it is possible that the coil is still defective. Replacing the coil temporarily with one which is known to be serviceable is recommended.

10. The condenser can be checked if a capacitance tester is available. Condensers should have a capacitance of approximately 0.25 mf. Checking with a "megger" (high-voltage ohmmeter) should yield a resistance of 5m ohms or better at 1,000v. Replace the condenser if it fails either test.

NOTE: *After testing, ground the condenser lead against the case to discharge it.*

As noted above, sparking at the points, or points which pit or burn rapidly would indicate a defective condenser. Bad condensers will cause mounds and matching depressions on the points.

11. If the trouble is a misfire, and the tests above do not pinpoint the problem, check the condition and operation of the automatic timing advance unit

CHARGING CIRCUIT

Voltage Regulator

A bad voltage regulator may cause the battery to go dead, or may overcharge it causing electrolyte loss, short light bulb life, etc. The regulator is located beneath the battery box, and is rubber mounted. It can be tested with an ohmmeter, continuity tester, or ammeter.

Voltage regulator location

1. If the battery goes dead, disconnect the three regulator leads (yellow, green, and black).

2. With an ohmmeter or continuity light, check for continuity between the yellow lead and the green lead. Check for continuity between the yellow lead and the motorcycle frame.

There must not be continuity in either case. If there is, the regulator must be replaced.

3. If an ammeter is available, connect it in series with the battery positive wire. Start and run the engine at more than 2,000 rpm. If the ammeter indicates that the battery is discharging, disconnect the regulator yellow lead and repeat the test. If the battery now shows that it is receiving a charge, the regulator must be replaced. If no change is noted, proceed with the rectifier and alternator tests which follow.

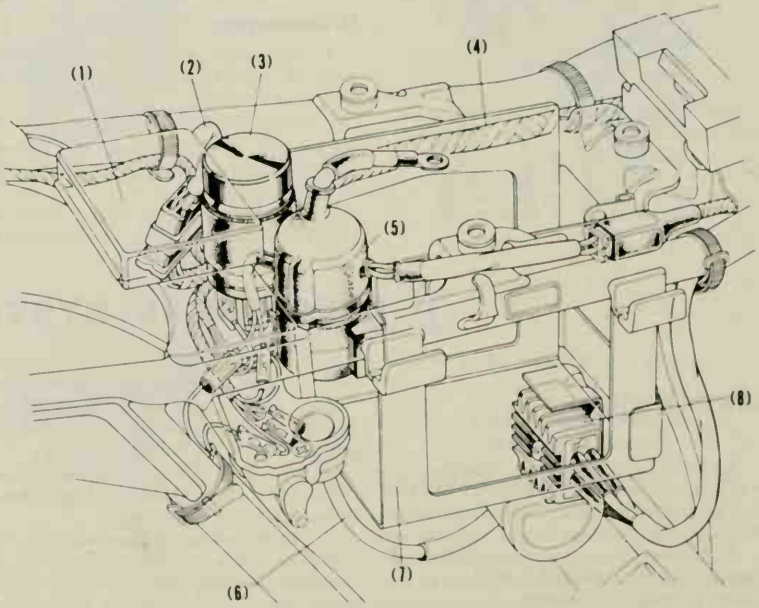
4. If the battery overcharges, check as follows:

Assuming that the battery is in good condition and *fully* charged, start the engine and connect a good voltmeter across the battery terminals. Run the engine at 4,000 rpm. The voltage across the battery should increase to between 14-15 volts, but not more. If the meter reads more than 15 volts, the regulator must be replaced.

NOTE: *This test will not be valid unless the battery is fully charged. To check this, run the engine until the voltage stabilizes, then disconnect the regulator black lead. If the voltage increases, the results of the test were valid.*

5. When mounting the regulator, be sure that the rubber dampers are in place. The regulator could be damaged by excess vibration.

Rectifier



The rectifier is located behind the battery (350) or under the battery case.

The rectifier should be checked in the event of insufficient battery charging. Tests can be carried out with a continuity light or a standard (low-voltage) ohmmeter.

CAUTION: *Do not apply high-voltage to the rectifier.*

1. Disconnect the leads and remove the rectifier from the machine.

2. The test involves testing current flow through the rectifier in both directions. The rectifier consists of four

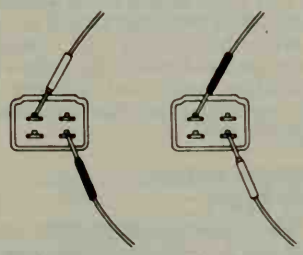
diodes. When in working condition, a diode will pass current in one direction only.

If the diode passes current in both directions, or in neither direction, it is defective. If any of the diodes is defective, the rectifier must be replaced.



Rectifier wires: (1) green, (2) red/white, (3) yellow, (4) pink

3. Connect the negative lead of the tester to the green wire, and the positive lead to the yellow, red/white, and pink wires in turn.

In each case, note whether or not there is continuity.

NOTE: *On an ohmmeter, "continuity" will be indicated by a resistance of 5–40 ohms. "No continuity" by a resistance of 100 or more ohms.*

4. Now reverse the tester connections, connecting the positive tester lead to the

Rectifier is checked by reversing the connections and checking for current flow

green wire, and the negative to each of the others in turn.

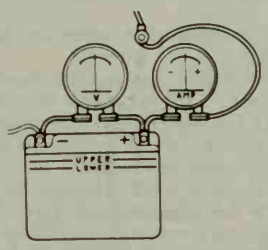
In every case, the reaction of the tester must be the opposite of the first test: i.e., if the first test showed continuity between two leads, reversing the tester connections must show no continuity.

Current flow in both, or in neither direction, for any two leads indicates that the rectifier must be replaced.

Alternator

The alternator should be checked in the event of low or no battery charging not attributable to the other components.

1. A dynamic output test can be carried out if a voltmeter and ammeter are available. The battery *must* be fully charged or the test may be invalid.



Hook up the voltmeter across the battery terminals, disconnect the battery red/white lead and connect it to the ammeter. Connect the other side of the ammeter to the battery positive terminal.

Disconnect the black regulator lead.

Start the engine and compare the voltmeter and ammeter readings with lights off and lights on (high-beam) at the given rpm.

lights off	15.5v/4A (max)	15.5v/4A (max)
high-beam on	15.5v/4A (max)	15.5v/4A (max)

Alternator output set-up

If the readings are not within 10% of the given specifications, the alternator should be replaced.

NOTE: *The alternator should not be excessively hot when this test is carried out.*

2. Using an ohmmeter or continuity tester, a static stator test can be carried out.

Disconnect the alternator wiring at the plastic connector.

Check for continuity between the white, the yellow, and the pink leads. Continuity must exist, or the stator assembly has a broken wire and it must be replaced.

Check for continuity between the yellow lead and the stator core. If continuity exists, there is a short, and the stator must be replaced.

Checking stator continuity

STARTER MOTOR

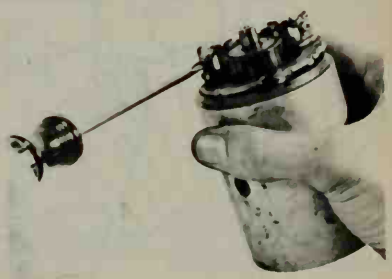
1. If the starter motor spins when the button is pushed, but the engine does not, the starter clutch is defective. Refer to "Engine and Transmission," for starter clutch removal and inspection procedures.

2. If the warning lights dim when the starter button is pushed, but the engine and starter do not turn over, the battery may be too low, or the starter may be defective.

3. If nothing happens when the starter button is pushed, either the starter solenoid is defective, or there is a loose wire in the electric starter circuit.

Removal and Disassembly

1. Disconnect the lead at the starter motor.



2. Remove the alternator cover, both sections of the left crankcase cover, and disconnect the neutral switch lead.

3. Remove the alternator rotor, using either the special puller, or the rear axle

4. Remove the starter sprocket setting plate (secured by a phillips screw), and remove the two sprockets and chain together.

5. Remove the two screws which secure the starter motor, and tap the starter out of the case.

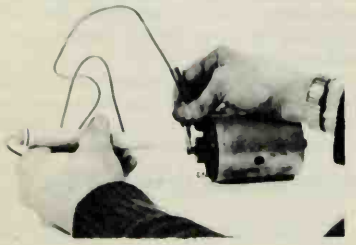
6. To disassemble the starter, remove the two long phillips screws and remove the end plates.

Disconnecting the brush leads

NOTE: *Exercise caution when removing the output side end plate as this contains the reduction gears.*

7. Disconnect the starter carbon brush leads (2) and remove the brush mounting plate.

Disassembly past this point is not necessary.

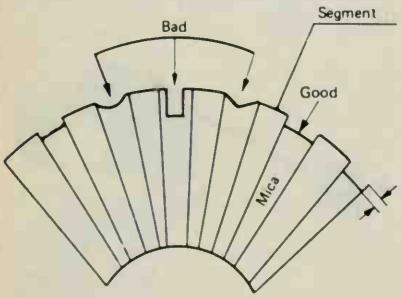


Inspection

1. Use an ohmmeter or continuity tester to check the starter motor.

2. Check for continuity between each of the commutator segments. There must be continuity between all of them. If there is a dead spot, the starter must be replaced.

Checking for continuity between each of the commutator segments



Checking for continuity between the commutator and the armature core

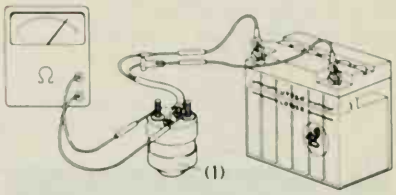
3. Check for continuity between the armature core and the commutator; there must be none. If continuity exists, the starter must be replaced.

4. Check for continuity between the starter lead terminal and the brush leads. Continuity must exist or the starter must be replaced.

5. Measure the length of each carbon brush. Replace them if either is less than 7.5 mm (0.3 in.).

Commutator groove condition

6. Clean the commutator surface thoroughly with a solvent. Check that there is no scoring on the commutator surface. The mica insulation should undercut the commutator segments by at least 0.3 mm (0.012 in.). If less than this, the mica should be undercut using a piece of a hacksaw blade or the like. Be sure to clean the commutator surface thoroughly after this operation. Remove any sharp edges.



Assembly and Installation

1. Reverse the above procedures. Be sure that the output side O-rings are in place.

2. After assembling the starter, check that the armature will turn without excessive binding.

Starter Solenoid

1. The starter switch (or solenoid) can be checked by disconnecting the high-tension lead from the starter motor, and pushing the starter button. The starter switch should click when the button is pushed.

Checking the starter switch (1)

2. If it does not, use an ohmmeter or continuity light to check for continuity across the switch's primary leads (black and yellow/red). If continuity does not exist, replace the switch.

3. Connect a fully charged 12-volt battery to the primary leads, then check for continuity across the starter switch high-tension leads as illustrated. If there is no continuity, replace the switch.

ELECTRICAL SWITCHES

All electrical switches are easily checked with an ohmmeter or self-powered continuity light after disconnecting the switch leads at the plastic connectors.

Ignition Switch

1. With the key turned to the first position, check for continuity between the black and red leads. If continuity does not exist, replace the switch.

2. With the key in the first position, continuity must exist between the brown and the brown/white leads.

3. With the key in the second position, continuity must exist between the red and brown leads.

Clutch Switch

1. Late models have a clutch starter switch incorporated into the clutch lever holder to prevent operation of the electric starter when in gear with the clutch engaged.

2. Check for continuity between the green and green/red switch leads. Continuity should exist only when the clutch is disengaged.

Brake Light Switches

1. Check for continuity across the front brake light switch terminals. Continuity should occur when the brake lever has moved 5–10 mm (0.2–0.4 in.), measured at the tip of the lever.

2. Check for continuity between the black and green/yellow leads to check the rear brake light switch. Continuity should occur when the brake pedal has moved about 25 mm (1 in.). This switch is adjustable.

Kill Button

1. The kill button should show no continuity between the black and the black/white leads when in either "off" position. When in the "run" position, there must be continuity.

Neutral Switch

1. Remove the left crankcase cover. With the transmission in Neutral, check for continuity between the switch and the crankcase. There should be continuity.

2. When the transmission is in gear, there should be no continuity.

Horn

1. If the horn will not function, connect a 12-volt battery directly to the horn terminals. If the horn does not sound it is defective.

2. If the horn does sound, check the horn button by disconnecting the light green lead and check for continuity between the lead and ground, which should be present when the horn button is pushed.

Headlight Switch (Late-Type)

1. There are five headlight switch leads and there should be no continuity between them when the switch is "off."

2. When the switch is "on," continuity must be present between the yellow and yellow/white leads, and between the black, brown/blue, and black/red leads.

Headlight Switch (Early Type)

1. When the switch is "off," there should not be continuity between the leads.

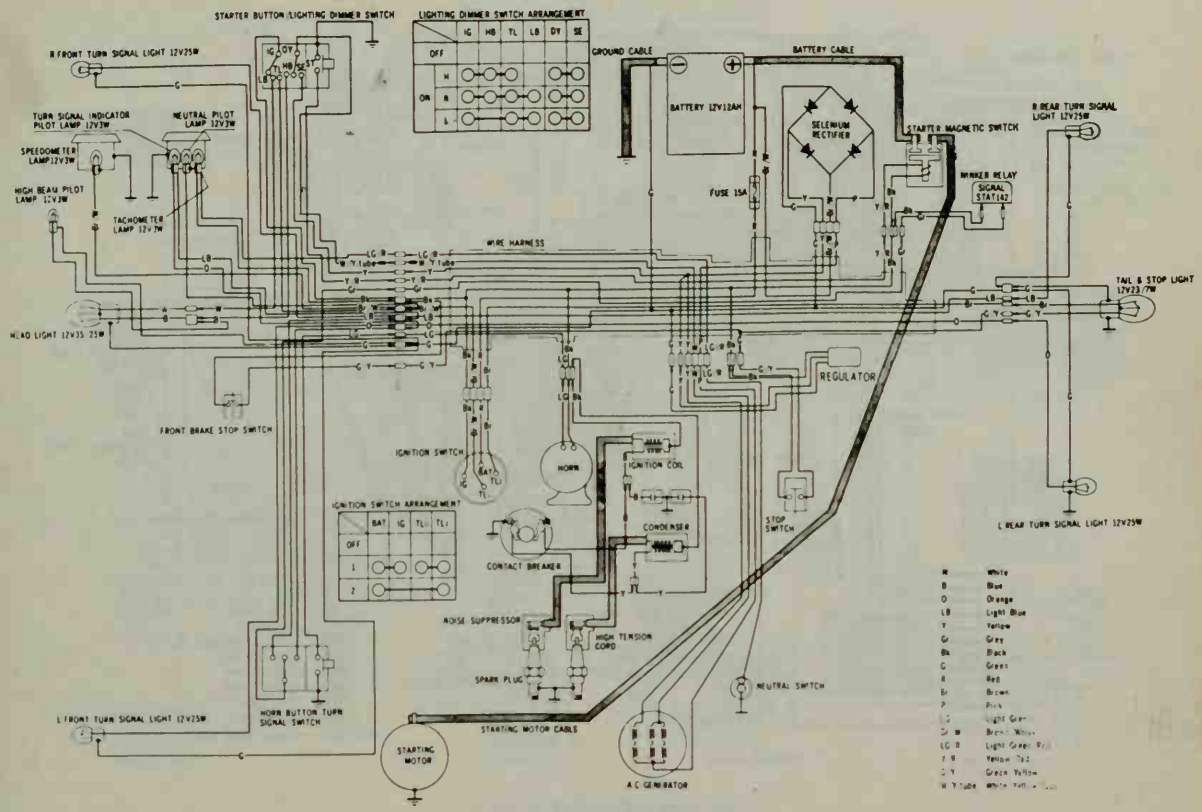
2. When the switch is in the high-beam position (H), there should be continuity between the yellow/white and the yellow leads and between the black, blue, and brown/white leads.

3. When the switch is in the low-beam (L) position, there must be continuity between the yellow/white and yellow leads, and between the black, white, and brown/white leads.

Dimmer Switch

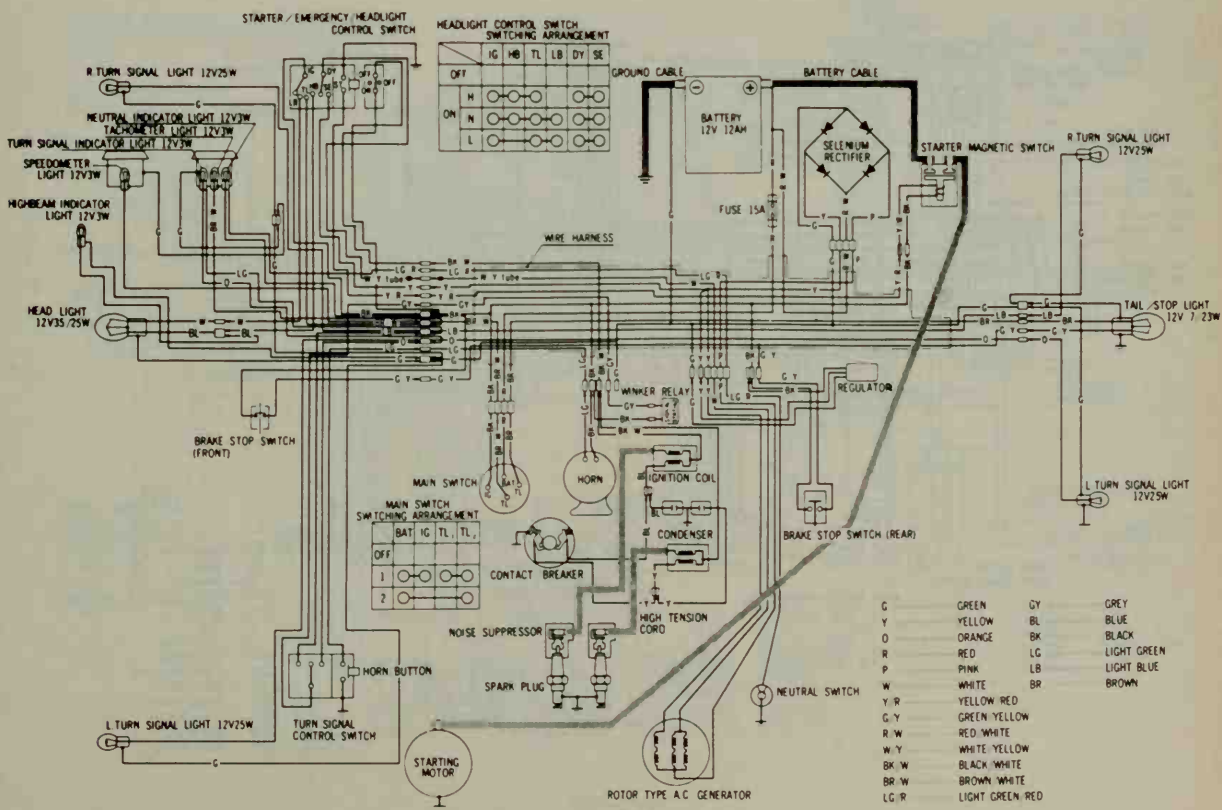
On late models with a separate dimmer switch on the left handlebar:

1. In the high position, there must be continuity between black/yellow and blue wires.



2. In the low-beam position, there must be continuity between the black/yellow and the white wires.

Turn Signal Switch



1. When the left-hand turn signal is activated, there will be continuity between the gray lead and the orange lead.

2. When the right-hand switch is activated, continuity will exist between the gray lead and the light blue lead.

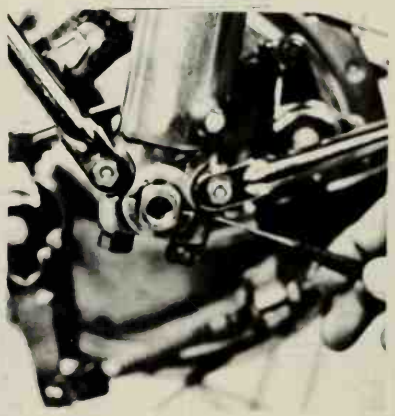
CHASSIS

WHEELS, HUBS, AND BRAKES

Removal and Installation



FRONT

Drum Brake

1. Place the motorcycle on the center stand, and place a support under the engine to raise the front wheel at least 2 in. off the ground.
2. Disconnect the speedometer cable from the brake plate after removing the phillips head set screw.
3. Screw the locknut off the front brake cable adjuster, and run the adjuster in to give as much slack in the cable as possible.
4. Remove the cotter pin from the brake lever on the brake plate. Then pull the lever back by hand and disconnect the brake cable from the lever and the brake plate.
5. Remove the bolt securing the brake anchor to the front hub.
6. Remove the two nuts, plain washers, and lockwashers from each axle cap. Remove the caps. The front wheel can now be removed.
7. To install, hold the wheel in place and install the axle caps, plain washers, lockwashers, and nuts in that order.

CAUTION: *The axle caps are machined unevenly (one side is slightly higher than the other) the high side MUST face the front. The front bolt should also be tightened first so that a small gap exists between the bottom of the fork slider and the axle cap at the rear. If in doubt which side is the high side, place a straightedge across the top of the cap, the high side should be apparent.*

8. Connect the speedometer cable to the brake plate, and secure it in place with the phillips head set screw.
9. Bolt the brake anchor to the brake plate. Connect the brake cable to the brake lever and then to the brake plate. Adjust the cable free-play to 10–20 mm (0.6–0.8 in.) with the cable adjuster on the brake plate.

Cap should touch fork at front with space at rear

Disc Brake

1. Place the motorcycle on the center stand, and place a support under the engine to raise the front wheel at least 2 in. off the ground.
2. Disconnect the speedometer cable from the speedometer drive housing after removing the phillips head set screw.
3. Remove the two nuts, plain washers, and lockwashers from each axle cap. Remove the caps. The front wheel can now be removed.

CAUTION: *Do not squeeze the brake lever when the front wheel is removed. This will force the piston in the caliper out.*

4. To install, hold the wheel in place with the speedometer drive housing facing slightly down and to the rear, and install the axle caps, plain washers, lockwashers, and nuts in that order.

CAUTION: *The axle caps are machined unevenly (one side is slightly higher than the other) the high side MUST face the front. The front bolts should also be tightened first starting on the disc side so that a small gap exists between the bottom of the fork slider and the axle cap at the rear. If in doubt which side is the high side, place a straightedge across the top of the*

cap, the high side should be apparent.

5. Connect the speedometer cable to the speedometer drive housing, and secure it in place with the phillips head set screw.

REAR

1. Place the motorcycle on its center stand so that the rear wheel is off the ground.

2. Remove the mufflers (CB models only), or remove the lower shock mounting bolts so the axle drops below the mufflers.

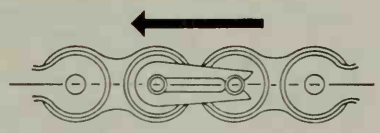
3. Remove the cotter pin, nut, lockwasher, and plain washer from the brake anchor bolt, and separate the brake anchor from the brake plate.

4. Remove the rear brake adjusting nut, depress the brake pedal, and separate the brake rod from the brake lever. Place the clevis pin, spring, and adjusting nut on the brake rod for safekeeping.

Disconnecting the rear brake anchor at the brake plate

5. Remove the cotter pin from the rear axle nut. Remove the axle nut and flat washer.

6. Remove the masterlink from the drive chain. Place the masterlink on the end of the chain for safekeeping. If the chain doesn't have a masterlink, loosen the chain adjuster locknuts and run the adjusters in. Move the wheel forward in the swing arm and slip the drive chain off the rear sprocket once the axle is removed. This can be done for either type of chain and does not require removal of the masterlink.



7. Pull the axle out from the right-side and remove the wheel assembly from the swing arm.

NOTE: *Place the wheel spacers on the axle in the order that they are removed, and screw the axle nut on the axle for safekeeping.*

8. To install the wheel: wrap the drive chain around the rear sprocket. Hold the wheel in place and slip the axle in place from the right-side. Be sure that the wheel spacers are in their correct locations. If the masterlink was removed, place both ends of the chain on the rear sprocket and install the masterlink as shown with the open end of the spring clip facing opposite the direction of rotation.

9. Turn the axle nut on finger-tight. Adjust the drive chain slack; the slack, measured midway between the sprockets, should be about ¾ in. Refer to "Maintenance."

10. Secure the brake anchor to the brake plate with a plain washer, lockwasher, nut, and a new cotter pin in that order.

DIRECTION OF TRAVEL

Install the spring clip with the closed end facing the direction of chain travel

11. Slip the brake cable or brake rod through the fitting in the brake lever and screw on the adjusting nut. Adjust the cable so that the brake pedal has 1 in. of free-play before the brake shoes contact the drum.

12. Tighten the axle nut to the proper torque. The proper torque for your model can be found in the "Chassis Torque Specifications" chart at the end of this section. Then back the nut off until a slot in the axle nut is lined up with a hole in the axle. Secure the axle nut in place with a new cotter pin.

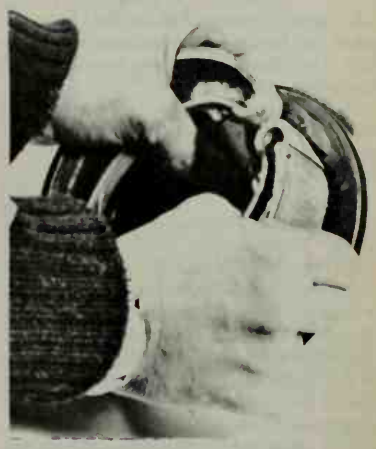
Drum Brake Service

All models use a single-leading shoe rear brake, while, a twin-leading shoe is used on the front. Hondas use brakes in which the lining is bonded to the brake shoe. Lining and shoe, therefore, are purchased and replaced as a single unit.

1. Remove the wheel from the motorcycle. On the front wheel, unscrew the axle. Remove the brake plate from the hub.

2. Brakes can be inspected on the brake plate.

3. Inspect the lining for wear. There should be at least 0.1 in. (2.5 mm) of lining material left (measured at the linings thinnest point) or the shoes must be replaced.



4. Inspect the linings for grooves or scoring. These may be caused by particles of dirt which have entered the drum. If badly scored, the shoes should be replaced. If scoring of the shoes is evident, the drum should be inspected for the same type of damage.

Be sure that there is no oil or grease present on the linings. Oil-impregnated linings must be replaced. If the linings show this condition, determine the source of the lubricant: defective wheel bearing oil seals, excessive chain lube, etc.

5. If the linings are usable, rough up the surface with coarse sandpaper. Then clean the linings with alcohol or laquer thinner. Clean the brake drum with the same solvent.

6. To disassemble the brake plate, remove the cotter pin(s) and washer(s) from the brake pivot(s). Grasp each shoe and fold them toward the center of the brake plate. They may be installed in the same manner.

7. Remove the brake springs. Remove the brake lever pinch-bolt(s) and pull the lever(s) off the splined brake cam(s).

Removing the shoes from the plate

NOTE: *The plurals refer to the twin-leading shoe brakes.*

8. Push the brake cam(s) out of the brake plate from the outside using hand-pressure or if necessary by tapping with a plastic mallet. Remove the plain washer and dust seals from the brake plate.

9. Check that the brake lever pinch-bolts are not bent. This can easily happen if they are overtightened. Replace any bolts in this condition. Inspect the brake lever splines and replace the lever(s) if these are worn or stripped.

10. Inspect the splines on the brake cam(s). These should be in good condition. Check that the brake cam(s) are not bent and that they can rotate freely in the brake plate passage. If it will not, use a fine grade of sandpaper on the camshafts and the surface of the brake plate passage.

11. Clean the cam(s) thoroughly in a solvent to remove any old grease, rust, or corrosion. Use sandpaper or emery cloth to polish the cams. Clean off any residue; before reassembly, smear the cams with chassis grease.

12. Inspect the brake plate for cracks or fractures, and replace it if necessary.

13. Check the condition of the brake springs, noting any twisted or fatigued hooks. Replace any broken, rusted, or old springs with new ones.

14. Clean all parts thoroughly with a suitable solvent, making a special effort to remove the dust and built-up dirt from the backing plate.

15. When reassembling the hub, note the following points:

a. Ensure that the brake cams are lubricated with chassis grease;

b. The use of new dust seals is recommended;

c. Lubricate the brake shoe pivot points with a little grease;

d. Install the shoes as on removal. Hook them together with the springs, and fold them down over the brake cam(s) and pivot(s). Install new cotter pins to the pivot points;

e. When installing the brake lever on the brake cam, be sure that the punch marks on the lever and cam align.

BRAKE DRUMS

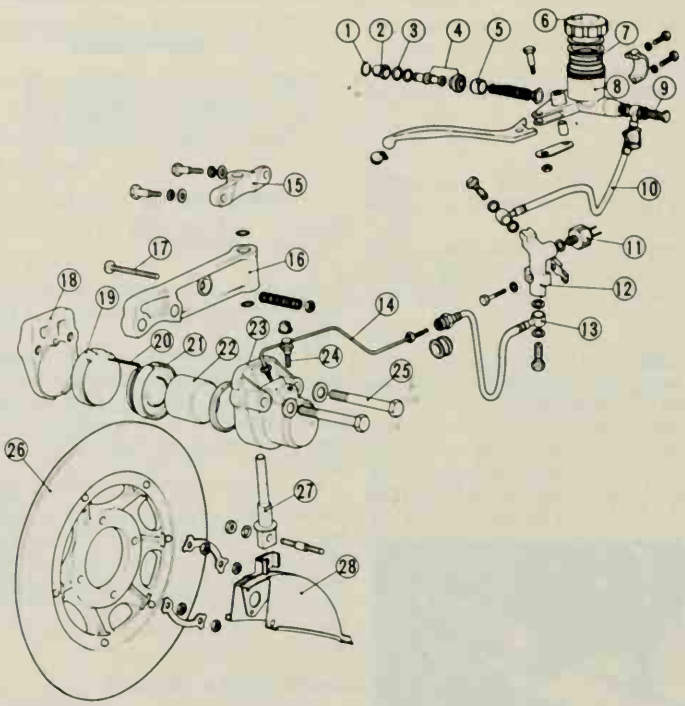
1. Upon disassembly of the hub, inspect the brake drum surface for condition. The drums must be clean and free from score marks or rust.

2. Rust can be removed from the drum surface with sandpaper. Polish the surface until it is shiny, then clean it thoroughly.

3. Alcohol or lacquer thinner can be used to remove dirt or deposits from the drum.

4. The drum should be checked for concentricity. An out-of-round condition is usually noticeable as an on-off-on feeling when the brake is applied while riding. With the wheel assembly mounted on the machine, spin the wheel while applying the brake very lightly. The rubbing noise of the brakes against the drum should be heard for the entire revolution of the wheel.

5. An out-of-round condition and most scoring can be removed by having the drum turned on a lathe.



Disc Brake Service

When handling disc brake fluid, observe the following cautions:

a. Brake fluid absorbs moisture very quickly, and then becomes useless. Therefore, never use fluid from an old or unsealed container;

b. Brake fluid will quickly damage paint. Place a protective cover on the gas tank;

c. Use only DOT #3 brake fluid.

FLUSHING

The brake system should be flushed out every 8,000 miles, or once a year.

1. Attach a length of vinyl tube, about 4 mm in diameter, to the bleed screw on the brake caliper and put the other end into a small container.

2. Remove the master cylinder cap, and the diaphragm. Loosen the bleed screw about ½ turn. Pull the brake lever slowly to the handgrip, then tighten the bleed screw. Release the lever. Repeat until the master cylinder is almost empty.

3. Add new brake fluid to the master cylinder and continue squeezing and releasing the brake lever slowly until the new fluid begins to come out of the vinyl tube. Bleed the system as outlined below.

BLEEDING

1. Needed for this operation are a torque wrench, a small cup, and a vinyl tube with an inside diameter of 4 mm.

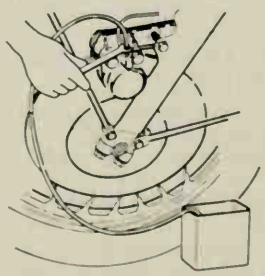
2. Be sure that the reservoir is topped up. After checking the reservoir level, replace the diaphragm and cap.

3. Connect the vinyl tube to the bleed screw on the caliper, making sure that it is a tight fit; then insert the other end of the tube into a small container with several inches of brake fluid in it. Be sure that the end of the tube is below the level of the fluid in the container.

4. Apply the brake lever *slowly* several times, then hold it ON.

5. While holding the brake lever on, loosen the bleed screw. The brake lever will be pulled toward the handgrip. Close the bleed screw BEFORE the lever bottoms out on the handgrip.

6. Repeat the procedure until the fluid issuing from the lower end of the tube is completely free of air bubbles.



NOTE: *During the operation, keep a check on the reservoir fluid level, maintaining it near its normal position.*

7. Tighten the bleed screw to 4.5–6.7 ft lbs.

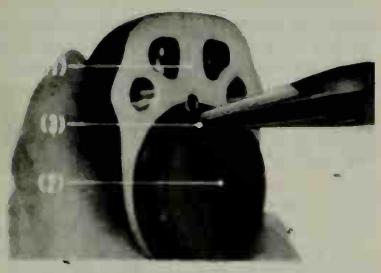
8. Top up the reservoir to the level line.

PAD REPLACEMENT

1. Both pads should be replaced as a set when either pad is worn past the red limit line.

Bleeding the disc brake

2. Disconnect the brake line from caliper A and cover the open end with the rubber bleeder cap, which will keep out dirt or foreign matter.



To remove the caliper halves for replacement of the pads, disconnect the brake line (1), remove the setting bolts (2), and remove the caliper halves (3 and 4)

3. Loosen the caliper setting bolts about ¼ turn.

4. Remove the front wheel. Now the caliper setting bolts can be removed, and the two caliper halves can be separated from the caliper pivot arm.

5. To remove pad B (the pad closest to the wheel) from caliper B, remove the cotter pin from the top of the pad.

6. To remove pad A (piston pad) from Caliper A, hold the caliper with the pad facing down, and tap the caliper lightly on top. The pad should fall out.

To remove pad B (2) from caliper B (1), first remove cotter pin (3)

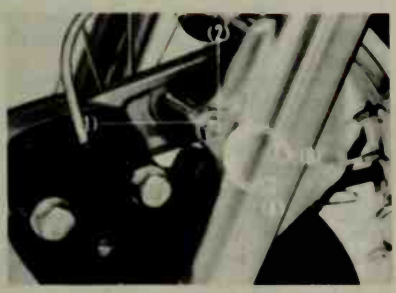
7. When installing pads, apply a small amount of silicon grease to the sides of the pad, and to the center of the back of the pad.

CAUTION: *Avoid getting any grease or oil on the braking surface of the pad.*

8. Install pad B into Caliper B and secure with a new cotter pin. Install pad A into caliper A with the slot in the pad facing the top of the caliper.

9. Install the two caliper halves to the caliper pivot arm and tighten the two setting bolts.

NOTE: *Fitting new pads in the place of a set which were considerably worn will cause the fluid level to rise. The excess fluid will be forced out of the inlet passage when the front wheel is mounted and the piston is forced back into the caliper.*



10. Install the front wheel taking care to locate the disc between the pads. It may be necessary to turn the caliper adjusting screw clockwise to fit the wheel. The piston pad may have to be forced back in the caliper. With the wheel in place connect the brake line and check that the setting bolts are tightened to the proper torque of 9–12 ft lbs. Adjust the caliper and bleed the system.

NOTE: *After installing new pads, avoid hard application of the brake for at least 50 miles.*

CALIPER ADJUSTMENT

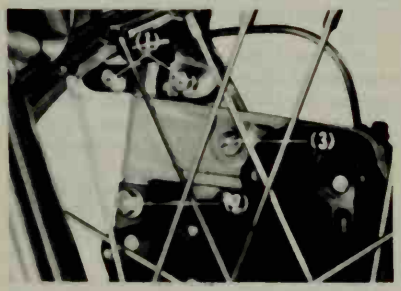
1. The caliper should be adjusted whenever the pads are replaced.

2. Place the motorcycle on the center stand, and place a support under the engine to raise the front wheel off the ground.

Caliper adjusting screw (1), and locknut (2)

3. Using a 10 mm socket, loosen the adjuster screw locknut. With a small screwdriver turn the adjusting screw clockwise until the wheel rotates freely, then rotate the adjusting screw counterclockwise until the fixed pad (pad B) just contacts the disc.

4. Turn the adjusting screw another ½–1 turn clockwise so that there is a small clearance between pad B and the disc. Tighten the locknut.



CALIPER REMOVAL AND DISASSEMBLY

NOTE: *A compressed air supply will be necessary to remove the piston from the caliper.*

1. Remove the front wheel.

2. Disconnect the hydraulic brake line from the caliper, and fit the rubber cap from the bleeder valve onto the end of the brake line to prevent dirt from entering the system.

3. Remove the caliper adjusting screw locknut from the adjusting screw and unscrew the adjusting screw from the right-side. Remove the adjusting screw spring.

Caliper mounting bolts (1 and 2), and adjusting screw (3)

4. Remove the three mounting bolts which secure the caliper pivot arm to the left fork slider. Remove the mud guard and the caliper assembly. The pivot shaft can be pulled from the pivot arm.

NOTE: *The two caliper halves can be removed from the pivot arm and disassembled without removing the pivot arm or the front wheel. To remove the caliper halves in this manner, see the section under "Pad Replacement."*

5. To disassemble the caliper, remove the two setting bolts from the caliper and separate the two caliper halves from the caliper pivot arm. Remove the two pads as described under "Pad Replacement."

6. Remove the piston from caliper A by blowing compressed air into the fluid inlet passage.

7. The piston seal can be removed from caliper A using a wood or plastic tool. However, note that if the cylinder walls are scored while removing the seal, the caliper half will have to be replaced.

CALIPER INSPECTION

1. Check pad wear. If either pad is worn past the red limit line, replace both pads as a set.

2. Measure the inside diameter of the caliper cylinder bore and the outside diameter of the piston. Compare the measured value with the service limit given at the end of this section; if either part is worn beyond its service limit, it must be replaced.

3. Check the bore in caliper A for scoring. If scoring is evident, the caliper half should be replaced.

4. Check the piston for scoring; replace it if scoring is evident.

5. Check the pivot shaft for wear, also check the pivot arm for wear at the pivot points. Replace as necessary.

6. Check the condition of the two pivot shaft O-rings. If they are torn or cracked they should be replaced with new ones.

CALIPER ASSEMBLY AND INSTALLATION

Since it is imperative that no dirt or foreign matter be allowed to enter the hydraulic system, assembly should take place in a clean area preferably on a sheet of white paper.

Clean and lubricate all internal brake parts with fresh DOT 3 brake fluid before assembly.

Use only genuine Honda replacement parts when replacing any parts in the brake system.

1. Install the pivot shaft into the pivot arm. Be sure to apply some grease to the pivot points. Note that an O-ring is fitted to either side of the pivot arm.

2. Mount the pivot arm to the left fork slider with the three mounting bolts. Install the adjusting screw, spring, and locknut.

3. Install the piston seal into the caliper using a wood or plastic tool. Take care not to score the cylinder bore. Installing a new seal is recommended.

4. Install the piston into the caliper half, then install the piston pad. Install the fixed pad to caliper B and secure it with a new cotter pin.

5. Install the two caliper halves to the pivot arm, and torque the setting bolts to 9–12 ft lbs.

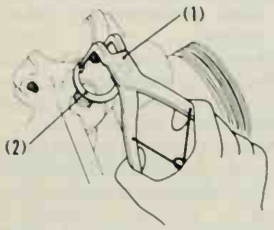
6. Mount the front wheel. Bleed the brake as described under "Bleeding". Adjust the caliper as described under "Caliper Adjustment".

BRAKE DISC

1. Check the disc for run-out by securing a dial gauge to the fork slider. If the run-out is 0.3 mm (0.0118 in.) or more, remove the disc and check it for warpage. Maximum warpage is 0.3 mm (0.0118 in.) If the disc is not warped, suspect the wheel bearings.

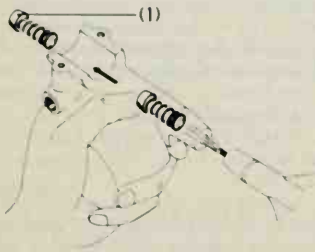
2. Measure the thickness of the disc. Minimum allowable thickness is 6.0 mm (0.236 in.)

3. To remove the disc, remove the front wheel, bend down the locking tabs on the disc securing nuts, and remove the nuts.



4. When installing the disc, care should be taken to tighten the bolts evenly and gradually until the proper torque of 13–16.6 ft lbs is reached. Ensure that the locking tabs are bent up against the flats on the disc bolts.

Master Cylinder

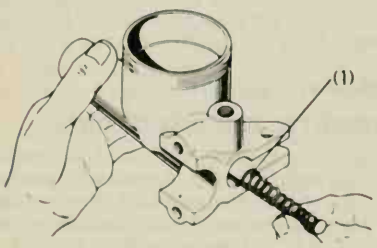


REMOVAL AND DISASSEMBLY

NOTE: *Be very careful when removing and replacing the master cylinder or refilling the reservoir. Brake fluid can remove paint or damage plastic in seconds and therefore should be handled with care.*

1. Place a cloth underneath the connection to absorb any spilled fluid and disconnect the brake line from the master cylinder. Cover the open end of the brake line with a plastic bag secured with a rubber band to prevent dirt from entering the brake system.
2. Remove the two mounting bolts and remove the master cylinder from the handlebar. Unscrew the reservoir cap and discard the brake fluid.
3. Remove the brake lever by unscrewing the pivot bolt.
4. Carefully remove the boot and 18 mm snap-ring.
5. Remove the piston, check valve, return spring, and primary cup by blowing compressed air into the brake line fitting or by carefully pushing it out with a wooden dowel.

Removing snap-ring (2), with snap-ring pliers (1)



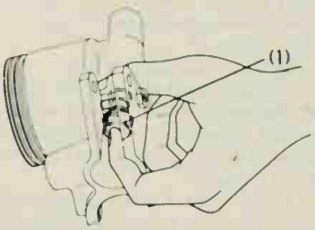
Removing the primary cup (1) with compressed air

INSPECTION

1. Clean all components in clean brake fluid.
2. Check the master cylinder bore for signs of wear, grooves, scoring, etc.
3. Check the piston for scoring or grooves.
4. Replace the primary cup with a new item each time it is removed.
5. Replace any rubber items which show signs of wear or age, cracks, brittle condition, etc.

ASSEMBLY AND INSTALLATION

1. Coat all internal brake parts with fresh brake fluid, including the bore in the master cylinder.



Installing check valve (1)

2. Install the return spring to the check valve and install them into the master cylinder. Be sure that the check valve is facing the correct direction.
3. Install the primary cup after lubricating it with fresh brake fluid.

NOTE: *Make sure that the primary cup does not turn sideways during installation.*

4. Install the piston assembly and 18 mm snap-ring. Install the boot and brake lever.

Installing primary cup (1)

5. Mount the master cylinder on the handlebar. Connect the brake line and torque the banjo bolt to 24–29 ft lbs. Fill the reservoir with fresh brake fluid and bleed the system as previously described.

NOTE: *Be sure that there is a joint washer on either side of the brake line where it is bolted to the master cylinder.*

Wheel Bearings

Removal of the wheel bearings necessitates removing the hub oil seals. These must be replaced with new ones upon reassembly.

DISASSEMBLY

1. Remove the wheel. For the front wheel remove the axle, side collar, and brake plate (drum brakes), or the speedometer drive housing (disc brakes). On the rear wheel, remove the brake plate and any side collars.
2. Remove any dust covers, or dust seals. Unscrew the bearing retainer, if fitted (all rear wheels; sprocket side and disc brake, disc side).

Removing bearing retainer (350 shown)

3. Pry out the oil seal. An oil seal is fitted to the disc side on disc brake wheels and on the side opposite the brake plate on wheels fitted with a drum brake. Use a small screwdriver, or, preferably, an elbow-shaped tool to remove the oil seal.
4. Remove the wheel bearings by reaching through the center of the hub with a long drift and tapping one of the bearings evenly around its circumference until it is removed. Be careful not to turn the bearing sideways in its seat on removal as there is danger of causing damage to the hub.

Removing wheel bearing

5. When either bearing is removed, the spacer tube can be remove from the hub. After removing the spacer tube, remove the other bearing in the same manner as the first.

NOTE: *On some models, especially high mileage machines, the hub should be heated gently with a propane torch in the vicinity of the bearing bosses to facilitate removal.*

INSPECTION

1. Clean the bearings and spacer tube in a suitable solvent, removing all of the old grease. At this point, it would be wise to clean out the hub as well.
2. Check the bearing bosses in the hub for scuffs, cracks, or distortion. If they are in any way damaged, the hub must be replaced.
3. Check the condition of the spacer tube, and replace it if damaged.
4. Bearing condition is very important. Check the balls themselves for pitting, wear, or rust.
5. Apply a few drops of light oil to the bearing and spin it. The bearing must rotate smoothly and freely. Any roughness or binding in rotation will necessitate a new bearing.
6. Note that the bearings must be replaced in pairs.

ASSEMBLY

Assembly is in the reverse order of disassembly; however, note the following points:

1. Obtain a good grade of wheel bearing grease (such as Lithium or Moly) to lubricate the wheel bearings.
2. Pack the wheel bearings until they are completely filled.
3. Place a small amount of wheel bearing grease to the inside of the hub and drive one of the bearings into its seat. Install the retainer if so equipped. Install the spacer tube and drive the other bearing into its seat. The sealed surface of the bearing must face the outside of the hub.

NOTE: *When a bearing retainer is fitted, the bearing closest to the retainer should be installed first. Then install and tighten the retainer, spacer tube, and the other bearing.*

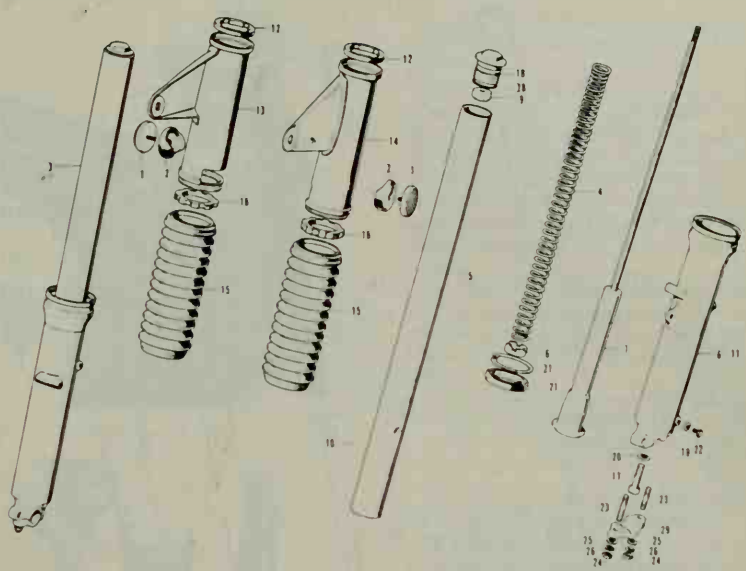
4. Replace all of the oil seals with new ones.

FRONT FORKS

Removal and Disassembly

Two basic types of front forks are used: internal or external fork springs.

1. Remove the front wheel and fender.
2. On disc brake models remove the three caliper mounting bolts and adjusting screw from the left fork slider, and lift the caliper away from the fork leg.



CAUTION: *Do not allow the caliper to hang by the brake line. Tie it out of the way with some string or wire.*

3. Loosen the fork filler caps as they may be difficult to remove once the fork leg is removed from the motorcycle.
4. On 360 models, remove the emblem from the lower triple clamp.
5. Loosen the pinch-bolts on the upper triple clamp (if fitted) and then loosen the pinch-bolts on the lower triple clamp. Remove the fork legs one at a time by pulling them down.

NOTE: *From this point disassembly and inspection refers to one fork leg, but applies to both.*

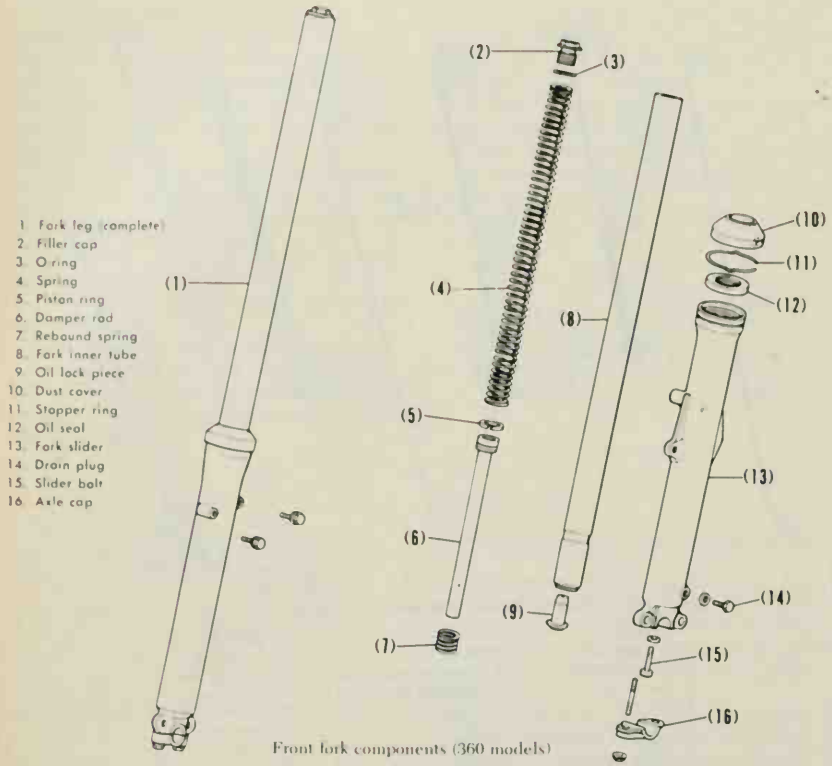
6. Remove the fork filler bolt from the top of the fork leg. Remove the spring (350 to K3, 360) and invert the fork over a container to drain off the oil.
7. Remove the rubber boot (if fitted). With an impact driver remove the screw from the bottom of the slider. Remove the circlip at the top of the slider, and separate the slider from the fork tube.
8. New oil seals should always be used once the slider has been separated from the tube. Pry out the old seal with a screwdriver, but be careful not to score the slider surface.
9. On early model forks with the damper components on the fork tube: remove the circlip at the bottom of the fork tube and take off the damper components. Use a new circlip upon assembly.

Slider screw must be removed with an impact driver



Inspection

1. Inspect the fork tubes for bends as might have been incurred in an accident. Replacement is recommended rather than attempting to straighten bent fork tubes.
2. Check that the surface of the tube on which the slider components move are smooth and free of rust or scoring. Minor rusting should be removed with fine emery cloth.
3. Check the spring condition; check that the spring heights are equal and that they are within the length specifications given at the end of this section. If either spring is compressed more than 0.25 in., both should be replaced.
4. Check that the damper rod (where fitted) is straight and that all damper components are clean.
5. On early-type forks, check the slider bushing for scoring or wear, and replace it if damaged.
6. Replace the fork filler cap O-rings if they are not in good condition.
7. Clean all metal parts thoroughly in a solvent and lubricate them lightly with fork oil before assembly.

Assembly and Installation

Assembly is in the reverse order of disassembly. Note the following points.

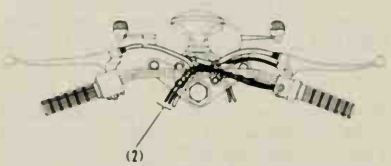
1. On the early-type forks the oil seal must be placed on the fork tube before the damper components, and then inserted in the slider with the fork tube.
2. On the later model forks the oil seal can be driven into the slider before the fork tube is inserted. Use the old seal on top of the new one to drive it in, then remove the old seal.
3. Refit the circlip, being sure that it is properly seated. The use of a new circlip is recommended.

Front fork components (360 models)

4. Fill the forks with the correct grade and quantity of oil and install the filler caps. Install the fork legs into the triple clamps. Tighten the lower triple clamp pinch-bolts and then check that the filler cap is tight. Tighten the upper triple clamp bolts (if fitted).

5. Adjust the brake caliper (if fitted) after assembly is complete.

HANDLEBAR



Disassembly

1. On models with a disc brake remove the master cylinder by unscrewing the two clamp bolts.

2. Disconnect the front brake cable (drum brakes) at the lower end by loosening the locknut on the cable adjuster on the brake plate. Screw the adjuster in to increase the amount of cable free-play. Remove the cotter pin from the brake lever and pull the lever back by hand, slip the cable end pin up and out of the brake lever.

3. Remove the brake (drum brake) and clutch cables from the handlebars by loosening the adjuster locknut and screwing the adjuster into the lever housing. Line up the slots in the adjuster screw and the locknut with the slot in the lever housing. Pull the lever back to the handlebar and pull the cable sheath out of the adjuster as the lever is released. Remove the cable end pin from the lever.

4. To disconnect the clutch cable from the lower end, remove the gearshift lever and chain cover. Screw the adjuster on the chain cover in to increase the amount of cable free-play. Disconnect the cable from the clutch release mechanism in the chain cover.

Route the throttle cables (2), as shown

5. To remove the throttle cable(s) from the twist-grip, unscrew the phillips head screws from the bottom of the throttle cable housing. Lift up the top of the housing and disconnect the throttle cable(s) from the twist-grip. To replace the cable(s), disconnect the cable from the carburetor and route the new cable as shown.

6. The electrical wiring for the horn, starter motor switch, dimmer switch, turn signals, and kill switch can be disconnected either in the headlight shell (350 models) or under the fuel tank (360 models).

7. Remove the handlebars by unscrewing the four bolts from the handlebar holders (two bolts on each holder). Mark the front of each holder before it is removed so that they can be installed in the same direction.

Inspection

1. Check the handlebar for a bent condition. It is recommended that a bent handlebar be replaced as straightened handlebars will be weakened and may break under extreme use.

2. Check that the brake, clutch, and throttle cables are not frayed at the ends. Replace any cable in this condition.

3. Check that the cables move freely in their sheaths. Replace any cable with a bent or kinked sheath.

Assembly

1. Install the electrical switches on the handlebar pulling the wires through the center of the handlebars using a lead of wire or string fastened to the longest wire.

2. Mount the handlebars on the upper triple clamp, and install the handlebar holders, with the punch mark on the handlebars aligned with the top of the lower holder.

CAUTION: *The handlebar holders are machined unevenly (one side is slightly higher than the other); the high side must face the front. The high side (front) on some models can be identified by a punch mark on the top of the holder. If in doubt which side is the high side, place the holder on a straightedge, the high side should be apparent.*

Tighten the front bolt first, so that the upper and lower holder are touching in the front and a small gap is left at the rear.

3. Connect the cables to the controls. When installing the twist-grip into the housing, be sure that the cable tensioner is correctly installed.

4. The remainder of assembly is in the reverse order of disassembly.

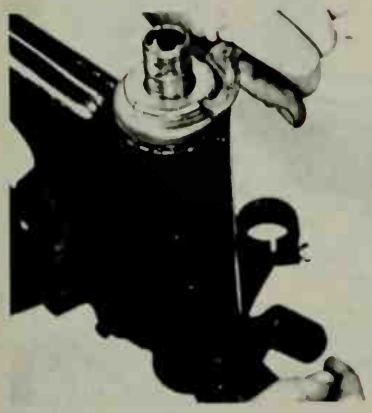
5. Check the operation of all controls before riding the motorcycle.

STEERING STEM ASSEMBLY

Bearing Adjustment

On models equipped with a friction steering damper, the damper should be loosened (counterclockwise) as much as possible so that it does not interfere with the bearing movement while checking or adjusting the bearing. If an oil damper is fitted, remove it from the steering stem.

1. The steering stem bearings are uncaged #8 balls. They are adjusted by means of a ring nut beneath the upper triple clamp.



2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender, place your other hand beneath the lower triple clamp at the frame lug.

3. Attempt to move the fork by pulling up on the tip of the fender. If play or movement can be felt at the lower triple clamp, the bearings are adjusted too loosely or are worn.

4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.

5. With the front wheel off the ground, release the front forks from a few degrees

off the centered position. The fork should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

Adjusting the steering bearings with the Honda pin wrench

6. To adjust the bearings, remove the front wheel, front forks, handlebars, and the upper triple clamp. The bearings are adjusted by means of the adjuster nut under the upper triple clamp.

7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above. Temporarily install the forks, upper triple clamp, and the steering stem nut to check the adjustment.

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

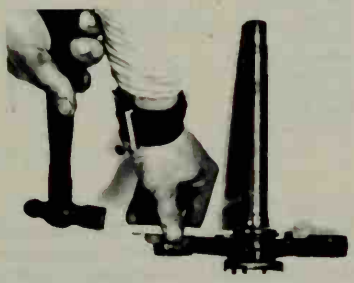
Removal

1. Remove the front wheel, front forks, and handlebars. If a friction steering damper is fitted, remove it by removing the two cotter pins from under the lower triple clamp, and unscrewing the damper rod and removing the friction plates. If an oil shock damper is fitted, unbolt it from the lower triple clamp.

2. Unscrew the steering stem nut and disconnect the speedometer and tachometer cables from their instruments. Remove the upper triple clamp.

3. Disconnect the wiring inside the headlight shell, and remove the headlight shell and the fork ears.

4. Loosen the steering stem adjuster nut with a pin wrench, then hold the steering stem up while unscrewing the adjuster nut the rest of the way off. Remove the steering stem top cone race and the ball bearings from the top race.



5. Carefully pull the steering stem out from the bottom. Some of the ball bearings from the lower race will probably fall out at this time so be prepared for this.

6. Remove the bottom cone race, dust seal, and dust seal washer from the steering stem if they are to be replaced. These will have to be pried off with a chisel, therefore only remove them if necessary.

7. The bearing races in the frame lug are a press-fit and should not be removed unless replacement is necessary. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable punch and tapping the race evenly around its circumference to remove it from the inside of the frame lug. Be sure that the race does not become cocked in its seat upon removal.

Removing the adjuster nut

Removing the lower cone race

Removing the bearing races in the frame lug with a hammer and punch

New races are installed with a suitable sized bearing driver: i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.

These races can also be installed using a block of hard wood of sufficient size to cover the race in place of a bearing driver.

Inspection

1. Wash the ball bearings in a suitable solvent.

2. Clean all of the old grease from the bearing race surfaces, steering stem, and frame lug.

3. Inspect the bearing race surfaces. They must be clean and smooth. That is free from any cracks, scoring, rust, or indentations. Run your finger around each of the bearing races. Note any roughness or ripples on the race surface. If any imperfections are noted, both the sets of races and all of the balls must be replaced.

4. Check the balls themselves for rust, pitting, scoring, or flat spots. If the balls are found to be defective in any way, the balls and both sets of races must be replaced.

NOTE: *Balls and races must always be replaced in a set as worn races will destroy new balls and worn balls will destroy new races.*

5. Check the dust seal for condition and replace if torn or cracked.

6. Check the steering stem for cracks or a bent condition; this is especially important if the bike has been involved in a spill.

Installation

1. Install the dust seal washer, dust seal, and lower cone race on the steering stem. Use a good grade of bearing grease to coat the bottom cone race and the upper race in the frame lug.

2. Embed 18 balls into the grease of the top frame lug and 19 balls into the grease of the lower cone race.

3. When the balls are in place, slip the steering stem through the frame lug and hold it in place while refitting the top cone race and threading on the adjuster nut.

4. Tighten the adjuster nut all of the way by hand, rotating the steering stem to work the grease into the balls.

5. Tighten the adjuster nut until the steering stem turns freely, but has no play.

6. Install the fork tubes, headlight assembly, and upper triple clamp, flat washer, and steering stem nut. Check that the stem moves freely to the steering lock of its own weight when released from 5°–10° off center; if not check for:

a. Steering bearings too tight;

b. Bent steering stem;

c. Worn races or balls.

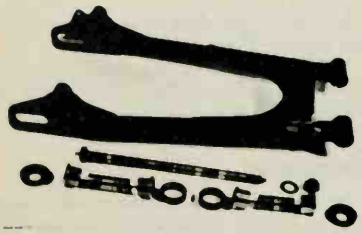
7. Install the front fender, front wheel, and handlebars.

REAR SHOCK ABSORBERS

No service to the rear shock is possible. In the event of oil leaks, bent or broken plunger shaft, dented or otherwise damaged case, the shock absorber must be replaced.

If the shock absorbers are somewhat old, and one fails in the course of normal usage, it would be a good idea to replace both shocks to insure equal damping characteristics.

CAUTION: *Do not attempt to disassemble the rear shocks. Gas is under high pressure.*



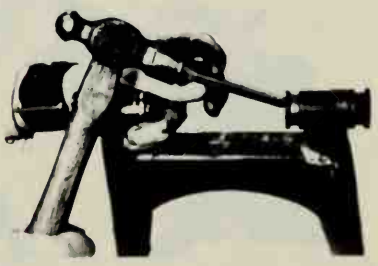
To check a shock which is removed from the machine, place the bottom end on the ground and use the weight of your body to compress it as much as possible. Release one shock and note the rebound behavior. If the shock returns quickly at first, then slowly returns to the normal length, it is serviceable. If it returns to its normal length all at once, it should be replaced.

SWING ARM

All Models

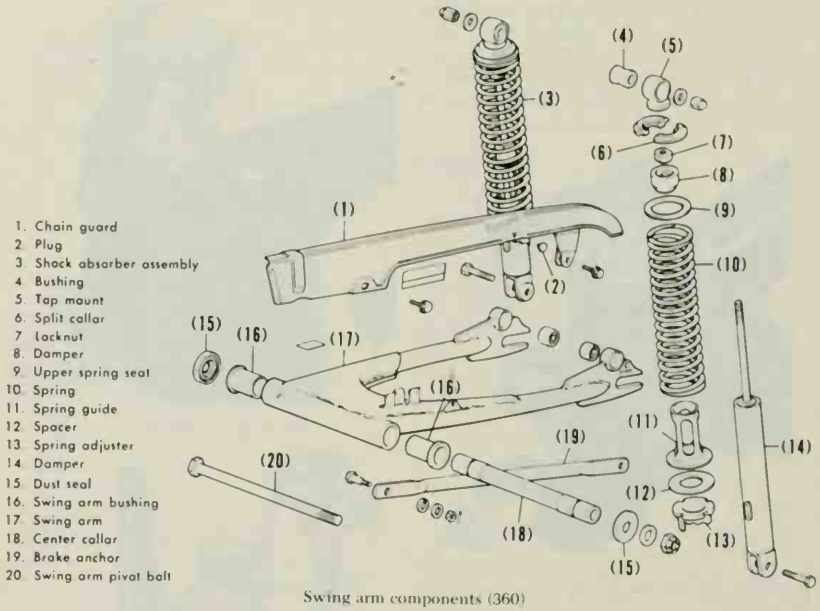
INSPECTION

1. Disconnect the chain. Remove the rear wheel and sprocket assembly.



Swing arm components (350)

2. Remove the shock absorbers and chain guard.
3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced or fixed.
4. Check that the rear wheel mounting plates are parallel.
5. Grasp the legs of the swing arm and attempt to move it from side-to-side. Any noticeable side-play will indicate that the swing arm bushings in the frame need replacement.



The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

REMOVAL AND INSTALLATION

1. 360 models: Proceed as above. Then unscrew the swing arm pivot bolt nut, and pull out the pivot bolt.
2. 350 models: Proceed as above. Then remove the shifter linkage. Remove two 6 mm bolts and one 8 mm bolt from each of the side plates. Remove the nut from the pivot bolt and remove the pivot bolt and the two side plates.
3. Remove the swing arm.
4. The swing arm should be inspected for cracks or fractures, especially around the welds.
5. After removing the swing arm, the dust seals and the swing arm bushings and center collars can be replaced. This should be done every 10,000 miles or more often depending on how the machine is used, or if the bushings are worn.
6. Using a small drift, push the center collar out of the swing arm. Remove the bushings, tapping them out with a long drift and hammer. Once the bushings are removed, they should be replaced.
7. Lubricate the new bushings and both the inside and outside of the inner collar with a good chassis grease. Press in one bushing, refit the inner collar and install the other bushing.
8. Install the two inner dust seals and swing arm on the machine. Install the two outside dust seals and side plates (350). After tightening the swing arm pivot shaft nut, move the swing arm up and down to ensure that movement is smooth and effortless.

Serial Number Locations

On all models, the frame number is located on the left-side of the steering head lug.

The engine serial number is located on the left-side of the engine, on top of the crankcase. These numbers should be used when ordering replacement parts for the engine or frame to ensure that the replacement part is identical to the part originally installed.

NOTE: *Beginning in 1967, Honda (and many other manufacturers) began using nuts and bolts manufactured to the ISO metric standard rather than the earlier JIS standard that had been widely used in Japan. ISO and JIS hardware is interchangeable in some sizes; however, the thread pitch in a few of the common sizes used has been changed and, in these cases, the hardware is not interchangeable. Note also that, except for the 10 mm size (6 mm diameter thread), the width (across flats) of size ISO nuts and bolts (relative to the thread diameter), has been reduced from that of JIS hardware. Early ISO parts are identified by an embossed dot on the bolt head or nut.*

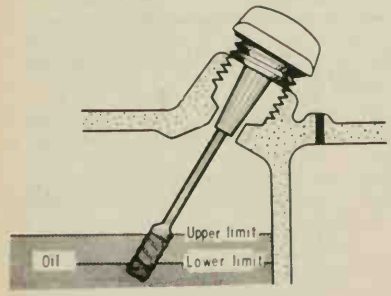
MAINTENANCE



NOTE: *Common maintenance procedures are explained in detail in "General Information."*

LUBRICATION

Checking Oil Level

The oil level is checked with the dipstick incorporated into the filler cap. The filler cap is located in the right crankcase cover. To check the oil level:

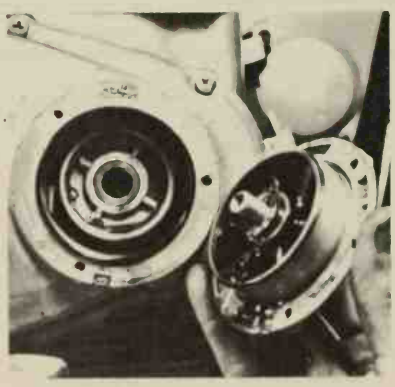
1. Start the engine and allow it to warm up for a few minutes.
2. With the motorcycle on the center stand on level ground, remove the dipstick and wipe it clean.
3. Reinsert the dipstick, allowing the filler cap to rest on the top of the threads of its hole. The oil level should be between the maximum and minimum marks on the dipstick. If the level is below the minimum mark, add enough oil to bring the level up to the maximum mark.

The dipstick should rest on the top thread of its hole when checking oil level

CAUTION: *Do not overfill.*

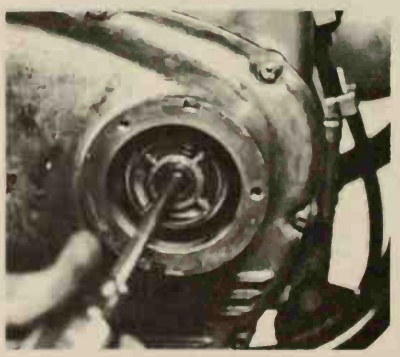
Changing Oil

The oil change interval is 1500 miles or 3 months.



Use oil with a service rating of "SE" only. SAE 10W–30 or SAE 10W–40 may be used at all temperatures. For temperature extremes, refer to the "Recommended Lubricants" chart at the end of this section.

1. Allow the engine to run for a few minutes until it is close to operating temperature.
2. Remove the drain plug from the sump, and allow the oil to drain for a minute or two, then kick the engine over a few times with the kick-starter (be sure that the key is off) to remove any oil remaining in the delivery system.

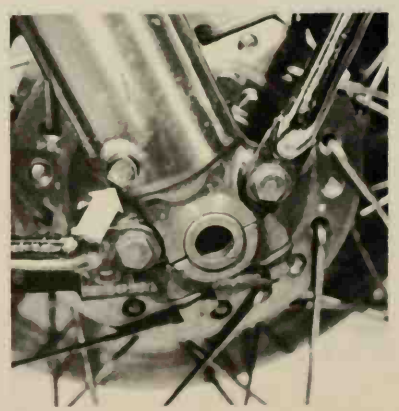


Oil Filter

A centrifugal oil filter is used on all models. The filter should be cleaned every 6,000 miles or 12 months.

1. Clean the oil filter in conjunction with an oil change. Drain the oil, but do not reinstall the drain plug.
2. Remove the three screws from the circular cover plate on the right crankcase cover. Remove the cover.
3. Remove the circlip from the oil filter. Screw a 6 mm (crankcase cover) screw into the center of the filter cap; this will pull the cap off.

Filter cover removed



Removing the filter cap

4. Remove the filter cap and the O-ring.
5. Clean the filter cap and the filter housing. Inspect the O-ring on the filter cap and replace it if damaged in any way.
6. Inspect the oil guide in the cover plate. The guide should be free to move in and out and have sufficient spring force behind it to hold it against the filter cap.
7. Install the filter-cap with the vanes located in the grooves on the inside of the filter housing, and secure with the circlip.
8. Install the cover plate using a new O-ring if necessary.

Front Forks

1. ATF is recommended for the front forks. If slightly stiffer damping characteristics are desired, use SAE 20 or SAE 30 oil.
2. Fork oil should be changed every 6,000 miles or once every year.
3. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Allow the oil to drain for several minutes into a suitable container, then pump the forks up and down several times. After most of the oil is expelled, turn the forks all the way to the right to completely drain the right fork leg, or all the way to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit the drain plug and tighten it securely.

Fork drain plug

Fork filler cap

4. Repeat the procedure with the other fork leg. Look at the old oil, if it contains water or inordinate amounts of dirt, the fork seals should be replaced.

5. Support the front wheel off the ground by placing a suitable jack beneath the engine. Remove the handlebar clamp bolts and move the bars aside if necessary. Remove the filler cap from the top of each fork leg. On models with internal fork springs, either move the spring to one side or take it out altogether to facilitate adding oil.

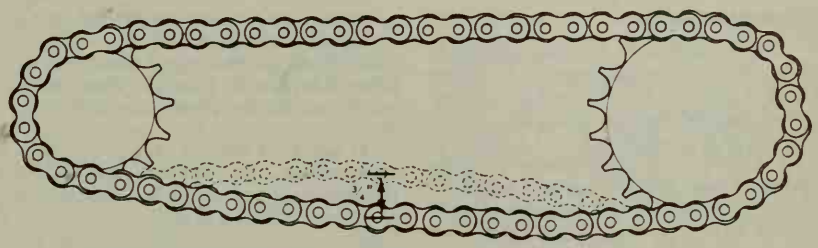
6. Add the correct amount of ATF to each fork leg. Capacities for each model are given in the "Maintenance Data" chart at the end of this section.

7. Inspect the condition of the fork filler cap O-ring, and replace it if it is torn or cracked. Fit the caps and tighten them securely. Tighten the handlebars front bolts first and pinch-bolts if they were loosened. Allow a moment for the oil to settle in the forks before operation.

Chassis Lubrication

1. The swing arm pivot is fitted with a grease nipple. This is on the end of the pivot bolt (450) or on the swing arm itself (500T). This item should be lubricated with a good grade of chassis grease every 3,000 miles. Grease should be applied until some of it shows at either end of the swing arm.

2. Wheel and steering head bearings are lubricated with bearing grease. This should be done every 6,000 miles. Refer to the "Chassis" section for procedures.



SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.

2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on the center stand so that the rear wheel is off the ground;

Chain slack should be about ¾ in. measured at the middle of the lower chain run

b. The transmission should be placed in Neutral;

c. The chain should be clean and well-lubricated;

d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably sprockets which should be replaced as soon as possible.

3. To adjust the chain, first back off the rear brake adjuster nut.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each chain adjuster bolt.

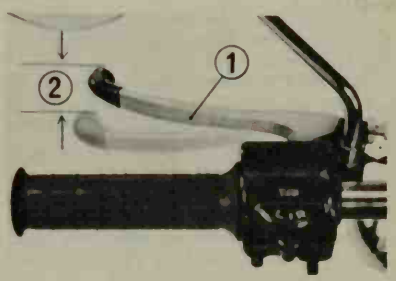
5. Turn each of the adjuster bolts in or out by equal amounts until the chain tension is approximately correct.

6. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

When adjusting the chain, be sure that the index mark on the adjuster aligns with the same swing arm mark on both sides

7. Tighten the axle nut and check the chain tension. The chain tension should also be checked with the weight of a rider sitting on the motorcycle when it is off the center stand; the chain should still have at least ½ in. of free-play. Correct if necessary. After adjustment is correct, torque the axle nut to 60–72 ft lbs.

Fit a new cotter pin and tighten the adjuster locknuts. Readjust the rear brake.



Clutch

Use the cable adjuster at the engine or at the handlebar to maintain the correct amount of cable slack. The clutch lever should be able to be moved 10–20 mm (0.4–0.8 in.) measured at the tip of the lever before the clutch begins to disengage.

If clutch operation is not satisfactory after making this adjustment, proceed as follows:

1. Apply a few shots of chassis grease to the clutch adjuster grease fitting and operate the clutch several times to distribute the grease. Make sure that the cable itself is well lubricated.

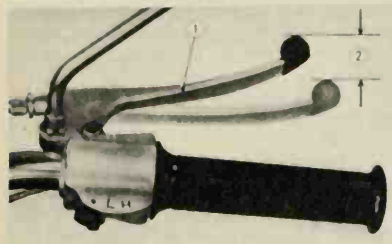
2. If either of the cable adjusters is close to the end of its adjustment range, back off its locknut and turn it in several turns.

The clutch lever should have 10–20 mm (0.4–0.8 in.) of free movement (2) before the clutch begins to disengage

After loosening the bolt (circle), turn the adjuster (arrow) to effect proper lever free-play

3. Loosen the clutch adjuster lockbolt on the left crankcase cover. Turn the adjuster as needed to effect proper lever free-play. Turning the adjuster clockwise will decrease free-play; turning the adjuster counterclockwise will increase the free-play.

4. Tighten the lockbolt; use either of the cable adjusters, if necessary, for fine adjustment. Be sure that the cable adjuster locknuts are secured.



Throttle Cable

The throttle cable free-play should be adjusted *after* the idle speed. This procedure is given in the "Tune-Up" section. The standard throttle cable free-play is 10–15° of grip rotation for all models.

1. Cable free-play is adjusted with the adjuster near the twist-grip. Loosen the locknut on the adjuster and screw the adjuster in or out until freeplay is correct. Tighten the locknut.

Front Drum Brake

1. Use the cable adjuster on the brake plate to allow about 20–30 mm (0.8–1.2 in.) of handlebar lever free-play before the shoes contact the drum. This free-play is measured at the tip of the lever.

The front brake lever should have 20–30 mm (0.8–1.2 in.) of movement (2) before the linings or pads are fully applied

2. This free-play can be maintained as the shoes wear by using the adjuster at the handlebar lever.

3. Late CL models are equipped with a brake wear indicator. If the arrows of the indicator align when the brake is fully applied, the brake shoes are worn to the point of replacement.

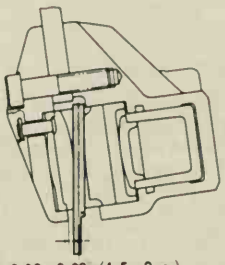
Disc Brake

Disc brakes need no attention other than a periodic check of the fluid level and pad wear:

1. After removing the reservoir cap and rubber diaphragm, check to see if the fluid is up to the level mark on the inside of the master cylinder. If the level is below the level mark, add enough DOT 3 brake fluid to bring the level up to the mark. Reinstall the diaphragm and the cap, and tighten securely.

Maintain the brake fluid level at the level line (arrow)

NOTE: *The fluid level will drop slightly as the pads wear.*



2. Check the brake pad wear, and replace the pads in a set if either one is worn past the red limit line (1972 and later).

On pre-1972 brakes, check the clearance between the front of the caliper and the disc. Replace both pads if clearance is less than 0.06 in. (1.5 mm).

Refer to the "Chassis" section for brake system service procedures.

3. If the brake lever feels spongy, bleed the system. This procedure can also be found in the "Chassis" section.

4. Early disc brake models are equipped with an adjusting screw on the handlebar lever bracket. After loosening the adjuster locknut, turn the adjuster to allow 20–30 mm (0.8–1.2 in.) of lever travel (measured at the tip of the lever) before the pads are fully forced against the disc. This adjustment usually will not need to be reset once lever travel is correct. If the lever travel becomes excessive and the brake pads are satisfactory, suspect air in the brake lines.

Brake pad wear check (early models)

CALIPER ADJUSTMENT

The caliper must be adjusted whenever new pads are fitted, or if the brake seems to drag.

1. Raise the front wheel off the ground.

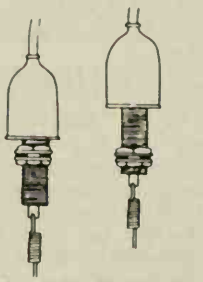
2. Loosen the adjusting screw locknut and turn the adjusting screw *counterclockwise* until the pads contact the disc. A slight drag will be noted when spinning the wheel.

Brake caliper adjustment screw

3. Turn the adjusting screw *clockwise* until the wheel spins freely; then turn the adjusting screw ½ turn more in the same direction and tighten the locknut.

4. Check that the wheel turns freely without drag. Check for proper brake operation.

Rear Brake



1. Use the adjusting nut on the end of the rod so that the brake pedal has 1 in. (25 mm) of movement before the shoes contact the drum. Check movement with the weight of the rider on the machine.

2. Late models are equipped with a brake wear indicator. If the arrows of the indicator align when the brake is fully applied, the brake shoes are worn to the point of replacement.

3. The pedal height may be adjusted for rider comfort by means of the stopper bolt provided. Adjust the brake after adjusting the pedal height.

Brake Light Switch

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch is mounted in a slotted bracket and secured by locknuts. Moving the switch up on the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later.

Do not turn the switch itself for adjustment. Turn the locknuts only, or the wires will become twisted and may break.

Generally, the brake light should come on just as the linings contact the drum.

Headlight Adjustment

1. Set the machine about 25 feet away from and perpendicular to a wall, preferably of a color which reflects light well.

The machine should be off the stand, and with a rider putting his weight on the machine as in operation.

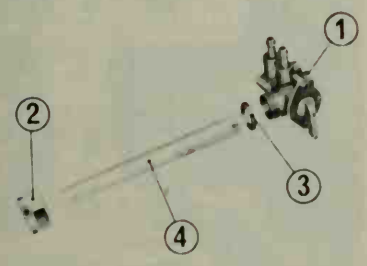
2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.

3. Vertical adjustment is made by loosening the two headlight shell mounting bolts slightly and pivoting the shell up or down.

4. Lateral adjustment is accomplished by means of the screw on the right-side of the headlight. Turning the screw clockwise will move the beam to the left; turning it counterclockwise will move it to the right.

Steering Stem Bearings

The steering stem bearings should be checked periodically and adjusted if necessary. Refer to the "Chassis" section.



FUEL SYSTEM

1. Fuel system maintenance involves cleaning the petcock and filter, cleaning or replacing the air cleaner, and cleaning the carburetors.
